THE ENCYCLOPEDIA AMERICANA

Indian, Education of the. Indian education as at present conducted in the United States is in no way the outcome of any deliberate plan on the part of the Federal government, but is directly descended from the first attempts to teach the Indians of Virginia, and particularly from like beginnings in Massachusetts, where the remarkable results of John Eliot (q.v.) were achieved.

Eliot's Work.—Eliot was actuated by high motives, and his simple measures were chosen with consummate wisdom. Having familiarized himself with the language, disposition, and character of his Indians, he secured their confidence and respect. Those who would follow him he gathered in towns, where he taught them the liberties and responsibilities of township government and the devices and institutions of civilized life, among which the Church and the school naturally occupied places of honor. A number of "choice Indian youths" he induced to attend English schools that they might prepare themselves for missionary work among their own people. He was warmly supported by "the corporation for the propagation of the Gospel in foreign parts," by the General Court of Massachusetts, and particularly by Daniel Gookins, the official superintendent of the Indians in Massachusetts. Eliot began his work in 1646. In 1674 there were 14 towns of "praying Indians," whose schools and churches, in the majority of instances, were administered by educated natives, and an Indian college had been founded at Cambridge. Yet in due time this success was swept away by the fears and prejudices which developed under the baneful influences of the Indian wars. Similar successful work under the direction of John Cotton and Richard Bourne in Plymouth colony shared the same fate.

Other Endeavors.—Followers of Eliot in the 18th century were John Sergeant at Stockbridge, Mass., and Eleazer Wheelock in Connecticut and New Hampshire. The work of Sergeant, which involved the establishment of day schools, of a boarding-school, and an experimental "outing system," was almost ideal in con-

ception, but ended with the deportation of his Indians to the West. Dr. Wheelock's labors led to the establishment of an effective training school and, indirectly, to the creation of Dartmouth College "for the education and instruction of youths of the Indian tribes in this land in reading, writing, and all parts of learning which shall appear necessary and expedient for civilizing and christianizing the children of pagans, as well as in all liberal arts and sciences, and also of English youths and any others." Only the last purpose was destined to achievement.

Surviving Influences.—But in spite of external failure, the spirit and much of the form of these early enterprises persisted. Their impress is observable to-day in almost every prominent feature of the Indian-school organization of the United States, notably in the establishment of day schools in or near Indian villages as a means of domestic and industrial uplifting of Indian family and village life; of industrial boarding-schools in territory occupied by Indians, to introduce among the young a taste for the refinements, duties, and responsibilities of civilization; of advanced training-schools in civilized English-speaking communities for the fuller equipment of "choice Indian youths" for full citizenship in such communities, or for missionary work in the ideals, institutions, and arts of civilization among their own people. It is seen in the universal stress in all schools upon instruction in husbandry, certain trades and domestic arts; in the "outing system," which places partially educated Indian girls and boys as paid helpers in suitable English-speaking families, and affords them instruction in the ordinary public schools; and in the importance attached to religious and ethical training.

Wrong Departures.—On the other hand, it is to be deplored that a number of valuable features of the early schools have been abandoned, and even supplanted by opposite tendencies—the unintelligent warfare against the Indian idiom; the introduction of certain brutalities of military discipline; an equally mistaken effort to wean Indian youth from Indian association by throwing contempt upon the Indian and by stimulating a feeling akin to hatred

INDIAN

of Indian family ties; and in general a policy of compulsion and repression, rather than a spirit of development and benevolent helpfulness. Serious harm came to government schools because patronage entered as a factor in the appointment of officers and employees. Thanks to the Indian Rights Association, the Mohonk Conference, and a number of other societies, in 1893 civil-service rules were applied to employees of the Indian schools.

History of Organization.—The successive steps in the organization of Indian schools have been as follows: After the Revolution little heed was paid to Indian education for 30 years. Only minor appropriations are recorded on the basis of treaties with a few tribes. But in the first quarter of the 19th century a religious revival directed attention to Indian education as a Christian and national duty. Congress responded in 1819 with an appropriation of \$10,000 in addition to certain treaty obligations. In 1820 the President was authorized to apply this sum annually in aid of societies and individuals engaged in the education of Indians. In 1823 \$80,000 was expended in 21 schools maintained by missionary bodies, \$12,000 having been granted by the government. In 1825 the number of such schools had risen to 38, their entire expenditure to \$202,000, of which the government, directly and indirectly, had contributed \$25,000. In 1848 there were reported in operation 16 manual-training schools, 87 boarding-schools and other schools. These schools continued to increase in number and efficiency up to 1873, under the control of missionary bodies, with scanty aid from the government, which had established only a few small day schools directly under treaty provisions. After 1873, however, the government entered upon an era of great activity in the establishment of strictly government schools. In 1877 Congress appropriated for schools outside of treaty provisions, \$20,000; in 1880, \$75,000; in 1885, \$992,800; in 1890, \$1,364,568; in 1895, \$2,060,695; in 1899, \$2,638,390; in 1900, \$2,936,080; 1901, \$3,083,403.65; 1902, \$3,251,254; 1903, \$3,531,220. The expenditures have doubled within the decade, and trebled within 15 years. During the quarter century the average attendance rose in more than like ratio. Increased appropriations naturally stimulated a desire on the part of the government to control expenditures. Moreover, the Constitution, by implication, at least, forbids the appropriation of public funds for denominational purposes. Conclusions unfavorable to government support of missionary schools were further strengthened by the fact that the Roman Catholic Church had gradually outstripped the Protestant missionary bodies and was absorbing the lion's share of government support. In 1893 the Methodist Episcopal Church withdrew from participation in government aid, but without abandoning its schools. In 1895 this example was followed by the Presbyterians and Congregationalists; in 1896 by the Friends; and in 1897 by the remaining Protestant denominations. This left only the Catholics in the field with an appropriation, and in 1901 it was withdrawn from them also. In 1894 Congress had declared its policy of abandoning all support of denominational schools, and this policy has gradually been followed out.

The Schools of To-day.—The present Indian schools under government control are day

schools, reservation boarding-schools, non-reservation boarding-schools, and industrial and normal training-schools. These in 1902 numbered 249, with an enrollment of 24,434 pupils; 323 other pupils were maintained by contract at Hampton and in white public schools.

Day Schools.—Day schools in Indian villages, or near Indian camps or settlements, are, as a rule in charge of a male teacher and his wife, or, as in the pueblos of New Mexico and in the Indian villages of southern California, of a white woman teacher and an Indian house-keeper. These teachers are employed for 10 months in the year; the male teacher's wife acts as housekeeper. The children spend 5 to 8 hours during the 5 days of the week under the care of these employees, and return to their homes in the evening. The instruction is of the simplest character. The children are taught to speak, read, and write English within narrow limits, to cipher, to draw, and to sing. They get some rudimentary notions of geography, of natural history, and of United States history. The methods are borrowed largely from the kindergarten and from object-teaching, and much stress is laid upon habits of cleanliness and order, mutual kindness, and prompt obedience. The boys receive some instruction in the use of tools, in gardening, and in some instances in the care of cows. The girls are taught sewing, cooking, and other arts of housekeeping. In the poorer Indian communities a noon-day lunch of a few simple articles is furnished. While these day schools accomplish comparatively little in conventional school-room work, they serve as concrete illustrations of a civilized Christian home which the Indians learn to respect and, in an appreciable degree, to emulate. Moreover, they reconcile the Indian with the idea of sending his children to school, and render him more willing in due time to entrust them to the care of boarding-schools, as well as more ready to appreciate and to accept the lessons of civilization. The most successful of 134 such schools in 1902, were located in Wisconsin, North Dakota, and South Dakota; the least successful, probably, among the pueblos of New Mexico, where the Indians live in a state of half-civilization which they owe to their Mexican and Spanish antecedents, and which fully satisfies their ideals.

Reservation Boarding-Schools.—There were 90 of these in 1902, averaging 125 pupils. They are in charge of a superintendent, assisted by a matron and such teachers, industrial and domestic helpers as the capacity and character of the school may require. In addition to regular teachers, the school is provided with a cook, a seamstress, and a laundress, whose office it is not only to supervise their respective departments, but also to instruct the girls in these arts. For instruction of the boys there is a farmer, an industrial teacher, and, at larger schools, a tailor, a shoe and harness maker, a carpenter, and a blacksmith. An experiment to provide for more methodical instruction in the use of tools, by expert manual-training teachers, failed because the Indian office would not afford a salary for this position sufficient to attract competent men. In 1894 the experiment of connecting kindergartens with these schools was tried, and proved eminently successful. At the present time there are 40 kindergartens connected with boarding-schools, and the use of kindergarten

INDIAN

methods and material has entered the primary classes in practically all these schools with similar good results. In the kindergarten the children spend from $1\frac{1}{2}$ to 2 hours each half-day. In most of the other schools children spend half a day in the school-room, and the other half-day in domestic or industrial work of a character suited to their age. Experience has proved that half-day instruction, at first forced upon the schools as an expedient, is commended by its good results.

The aim of the school-room work is to teach reading and writing within the usual limits of primary work; arithmetic for the needs of ordinary daily life; rudimentary geography and United States history; drawing and singing; the laws of hygienic living; garden and orchard work; and familiarity with the simpler requirements of agricultural and domestic industries suited to the locality. Moreover, in a few of the larger schools, the older boys have much opportunity to acquire skill in carpentry, blacksmithing, tailoring, and shoemaking. These institutions are to the children not only school, but home and community. The institution gives them shelter, food and clothing; it accustoms them to habits of cleanliness and decency; it cultivates their aesthetic tastes; it labors to secure right moral attitude, and in its Sunday-school seeks to stimulate the religious life of the children. The superintendent of the reservation boarding-school is subject in his work to the control of the Indian agent, who as representative of the government, administers the reservation's affairs. Inasmuch as these agents are selected on partisan grounds, usually at the suggestion of local politicians, this arrangement is fraught with danger to these schools.

In 1893, under civil-service regulations, there came some improvement. Still with reference to minor employees the superintendents, and even the Indian office, were powerless, and frequently good superintendents were forced out of service by combinations against them among the appointees of the agent, or through the aid and influence of unscrupulous partisan inspectors or supervisors. But in 1896 all employees of the school service were placed under civil-service protection, and since that time there has been marked improvement in the conditions and work of these schools. To a certain degree these evils still persisted, however, because of the power and political bias of the agents; but of late the government has adopted the policy of replacing the agents with bonded school superintendents, 22 agencies now being under such control. There has been decided gain in the equipment, in the sanitary condition, in the general character of employees, and in the conduct of the schools. For the Indian office, relieved of attention to office-seekers and their patrons, has been enabled to pay increased attention to the schools themselves. In the reservation boarding-schools instruction continues through 40 weeks; but often some children are kept at the school throughout the year.

Non-Reservation Boarding-Schools.—Of these there are 25. Seven of them are industrial training-schools, and three others are industrial and normal training-schools. The remaining 15, in their original scope of work, differed little from the reservation boarding-schools. But the superintendents of these schools are bonded and directly responsible to the Indian office. There

is no intervening Indian agency, and the consequent sense of responsibility and self-respect in the head of the school finds its reflection in the attitude of his subordinates, as well as in that of the pupils. These schools are, as a rule, located at a distance from the Indian country, and in the vicinity of American towns which afford contact with the amenities of civilized life. Members of many different tribes are also brought together, and tribal antagonisms are broken down. The pupils are older than those at reservation schools, and some have had previous training in day schools or reservation boarding-schools. Because far away from their Indian homes, and near to English-speaking communities, they gain a better control of English; class-room work reaches far into the advanced grammar-school courses of study, with special stress upon language practice, arithmetic, geometry, geography, history, nature study, drawing, and civil government. Instruction in domestic and industrial arts is made effective by frequent opportunities directly to observe their practical applicability and value. The superintendents are paid from \$1,200 to \$1,500 per annum. Other employees are paid on the same scale as in reservation schools. The most noted and successful of these schools are located at Flandreau, S. D.; Pipestone, Minn.; Mount Pleasant, Mich.; Fort Mojave, Ariz.; Carson, Nev.; Perris, Cal.; Tomah, Wis.; Wittenberg, Wis.; Fort Lewis, Colo.; and Pierre, S. D.

Industrial Training-Schools.—There are schools of this class at Carlisle, Pa.; Chemawa, near Salem, Ore.; Chiocco, Okla.; Genoa, Neb.; Albuquerque, N. M.; Lawrence, Kan. (the Haskell Institute), Grand Junction, Colo.; Santa Fe, N. M.; Phoenix, Ariz.; Fort Shaw, Mont. The most strenuous effort is now carried on at Chiocco; organized 1884; a large plant with a capacity of over 500 pupils, and a fine farm of about 9,000 acres. In organization these schools are similar to the schools just described, but in the scope of their work and in equipment they excel in a high degree. The government in 1894 added normal departments at Carlisle, at the Haskell Institute, and at Santa Fé. The experiment proved fairly successful with Carlisle and the Haskell Institute, at Santa Fé slightly so for a time, but of late it has shown better results there.

Contract Schools.—In addition to maintaining these strictly government schools, the Indian office up to 1901, as before said, paid by contract for the education of many hundreds of Indian pupils distributed in Catholic mission boarding-schools, in Catholic day schools; at Lincoln Institute, Philadelphia, and at Hampton Institute, Hampton, Va. In the appropriation for that year, the aid was withdrawn from all but the last-named, where 120 pupils were contracted for. Besides these, the government since 1891 has endeavored to place Indians in white public schools where there are many whites and few Indians, as the most rapid means of civilization. The antagonism of local or State authorities to this coeducation has made this plan a failure in some places; in others there has been some success. Rising from 8 to 45 between 1891 and 1896, the number of such schools has gradually sunk to 16 in 1902, with 110 pupils contracted for out of 189 enrolled, and average attendance of 98.

INDIAN AFFAIRS

Supervision.—Direction of the Indian schools rests with the Indian office, which is under the supervision of the secretary of the interior. In the Indian office the details of the work are entrusted to the education division, to which all reports are made, and by which all directions and orders are drafted and issued. The education division is aided in its work by the superintendent of Indian schools and by 5 supervisors, assigned in their work to 5 districts respectively. These officials constitute a branch of the Indian-school service which occupies a very uncertain position. They have duties, but no rights. A similarly anomalous relation exists between the commissioner and the secretary of the interior with regard to all matters which the latter may wish to control directly. For this purpose the secretary has established under his direct control an Indian division, independent of the Indian office, to which all orders and directions the secretary may designate must be referred by the Indian office for approval. The power of this Indian division is further reinforced by a corps of inspectors in the field, appointed on partisan grounds, and responsible to him alone. Technically the superintendent of Indian schools may appeal from the commissioner to the secretary of the interior, and the commissioner from the decision of the secretary to the President. In view, however, of the hopelessly autocratic relation that runs through the chain, that is practically out of the question. Under these conditions, the fact that Indian education has prospered reflects credit upon all concerned.

Schools of Indian Territory.—The schools of the so-called "five civilized tribes" of Indian Territory are not included in the above sketch. The 5 tribes in 1900 included 25,639 Cherokees, 10,321 Choctaws, 7,963 Creeks, 5,872 Chickasaws, and 1,662 Seminoles. In addition there were in the Territory 36,853 freedmen and 302,680 whites. Missionary zeal availed itself promptly of this field for its efforts. Substantial boarding-schools were erected, more particularly by the Presbyterians, Methodists, and Baptists. In due time, however, the Indian authorities began to make appropriations for these schools. Ultimately they took entire charge of them. Unfortunately, administrative affairs were largely in the hands of whites, who, by intermarriage or bribery, had been adopted into the tribes, and there came over the schools, as well as over all other public interests, the blight of extreme partisanship and nepotism, which rapidly degraded them in character and efficiency. In 1808 the government at Washington assumed supervisory control over the affairs of all these tribes except the Seminoles. The conduct of the schools and orphan asylums in the 4 tribes involved was placed under the direction of a superintendent of schools in Indian Territory, appointed by the secretary of the interior. Under him there is for each of the tribes or nations a supervisor of schools, whose duty it is to inspect the educational institutions in his district, and to assist in their organization and conduct. The superintendent reports to the commissioner of Indian affairs at Washington through the United States inspector for the Indian Territory, who is his immediate superior. The initial report of this superintendent showed in the 4 tribes 24 boarding-schools, with an enrollment of 1,758 pupils, and an average attendance of 1,480, taught and cared for by 234 employees

at an annual expense of \$236,824. This does not include 363 neighborhood schools, in which more than 10,000 children are taught at an annual expense of \$113,380, which, in character and equipment, show great inferiority.

WILLIAM N. HAILMANN,
Ex-Supt. Indian Schools.

Indian Affairs. The prevalent idea that the national government has always striven to dispossess the Indians from the lands they occupied, or has sympathized with such efforts, is the exact reverse of the truth. From its foundation until now, its history presents an unbroken record of quarrels between Indians and bordering or interdwelling white settlers, in which the government has been slowly and reluctantly pushed on to interfere; sympathizing with and justifying the Indians against its own citizens, its commissioners usually reporting in their favor, and even its generals in later days blaming the whites for the troubles; its courts deciding in their favor; attempting pacification amid local outrages against them, rebuffing appeals for aid, and only using its armies to reduce the Indians and its administrative power to remove them when it was no longer politically possible to leave them in possession. Even then, it has meant to deal righteously by them; but the complexity of the problem — one may say its insolubility till the country was very strong and the Indians very weak — along with the universal curse of "spoils" in the administration — has hindered success. While until 1887 there was no consistently formulated plan, there has been a sequence of government panaceas in a steadily descending line. First, there was to be one vast Indian reservation, large enough to give them all the hunting-room they needed, and so far from the United States that our growth would never reach to them and create more troubles; then three great reservations, to prevent so formidable an Indian district and internecine Indian wars; then a number of small ones, to segregate hopelessly hostile tribes, enable better training into civilized existence, and protect them from depredations; lastly, no reservations, but severalty ownership and individual citizenship. These changes of policy have been due not to fickleness or visionary causes, but to broadening experience and varying conditions.

The policy of removing the Indians west of the Mississippi was first formulated by Jefferson, who in a proposed constitutional amendment (1803) set off the Louisiana Purchase north of the Arkansas as a pure Indian country, in which no land was to be sold to whites. This was carried out, on a much reduced scale, in the formation of Indian Territory (q.v.) by act of 30 June 1834; by another act of same date a superintendent of Indian affairs was appointed, no one to trade or settle in the Indian country without permission from him or his agents. Previous to this the Indian matters had been under the War Department; in 1849 they were transferred to the new Department of the Interior, of which they still form a bureau. Under the commissioner of Indian affairs are eight inspectors and a large variety of subordinate officials and employees. The Indian agents, though under his control, are appointed by the President, for four years, with bonds; on their

INDIAN ART

action depends often peace or war to great white populations, but in too many cases they have been the football of politics, and sometimes scandalously unfit for their places.

The legal theory, until a recent date, was that each tribe was a nation, but not a foreign nor independent one; a "domestic dependent nation," but with which, nevertheless, all intercourse was to be conducted through special commissioners appointed by the President. In 1871 Congress abolished this method of procedure, and substituted immediate Congressional control, but the fiction of Indian nations remained; nor, indeed, could any other system well be applied so long as the Indians were recognized as national wards, and could not be made a part of the regular republican system or thrown into the current of unrestricted competition. It was the general plan to let the larger and better advanced ones, as the five "nations" of the Indian Territory, govern themselves and thus develop political life, including a full judiciary system. But the smaller ones could not be thus left, even in leading-strings; and in all, the government has recognized its duty to watch over their ignorance, improvidence, and savage instability of will and emotion from either violence or cunning on the part of the whites. Traders with them must have certificates of good character and be licensed by the Indian commissioner, and the goods they sell are subject to regulation; no one can hunt, cut timber, or pasture cattle on Indian lands without the agent's permission; intoxicating liquors may not be sold to them. Still more important and beneficial is the educational work, which has not only been carried on by churches, missionary societies, and private individuals from early times, but has been actively forwarded by the government. The five civilized nations of Indian Territory had their own school system, of considerable extent; but for others, and even for those where needed, the President was empowered in 1865 to appoint instructors of Indian children in reading, writing, arithmetic, and agriculture, and in 1882 to appoint an inspector of Indian schools. (See INDIAN EDUCATION OF THE.)

From 1877, when a \$20,000 appropriation was made for Indian schooling, to 1900, when over \$3,000,000 was appropriated, over \$35,000,000 had been thus expended by the government. It has spent since its foundation nearly \$400,000,000 on the Indians, outside of the cost of wars against them; and the present expenditure is about \$10,000,000 a year. In 1900 it was maintaining over 45,000 wholly by rations, and 12,500 partly, at a cost of about \$1,250,000 per annum; and paying annuitants (partly from trust funds derived from sales of their lands) over \$1,500,000.

On 8 Feb. 1887, however, an act was passed, amended in 1890, to sweep away as soon as feasible all this system of tutelage and pauperization, in the belief that abolition was best for Indians and whites alike. All reservations were to be surveyed; all Indians who wished to take up lands in severalty to a certain amount might do so—and by the act become citizens, as well as all who had previously done so under treaties and Congressional enactments, over 10,000 in number. Up to 30 Oct. 1900 6,736,514 acres had been so allotted, to 56,996 Indians; about 2,000

a year comply with the permission; and a few years will see an end of Indian tribes except as historical reminiscences. Many of these new citizens are made voters by their States: there are over 20,000 such in the United States at present. See CHEROKEE; CHEROKEE NATION v. GEORGIA.

Indian Art. In none of the fine arts except architecture have the Hindus attained much eminence. Their paintings are of very little merit, though the walls of temples, of palaces, and of the better class of private dwellings are often ornamented at great cost with pictures illustrating the characters and events of their mythology. More attention has been paid to sculpture than to painting, and in the temples cut from the living rock great numbers of statues are contained, some single figures and others large groups. Many of these are bold and spirited in design, though the human form is not exhibited in good proportion nor with its parts well developed.

Indian Architecture, however, comprehends a great variety of styles, among which we may distinguish, as the most important, the Buddhist, the Jaina, the Dravidian or Southern Indian, the Chalukyan, and the Modern Hindu or Indian-Saracenic styles. The history of Indian architecture commences in the 3d century B.C. with the religious buildings and monuments of the Buddhists. Among the principal forms of Buddhist architecture are first, the *topes*, *stupas*, or towers built to mark some sacred spot, and the *dagobas*, constructions of a similar nature, containing relics of Buddha or Buddhist saints. These buildings generally consist of a circular stone basement, varying from 10 or 12 to 40 feet in height, and from 40 to 120 feet in diameter, on which rose a rounded domical structure, generally of brick or small stones laid in mud, the whole edifice rising sometimes 50, sometimes 100 feet high. Second, the rock-cut *chaitya* halls or churches, and the *viharas* or monasteries. Most of these are found in Bombay; some also in Bengal and Behar. In rock-cut buildings architectural skill is confined to the façade and the interior. Among the most notable for beauty of design are those at Ajanta, and, finest and largest of all, the great *Chaitya* cave at Karli, near Bombay, the date of which is probably about 80 B.C. Another interesting example is at Ellora. The Jaina style is a development or corruption of the pure Buddhist. It is characterized by the square or polygonal court, the twelve-pillared dome, the slenderness and elegance of the columns, the horizontal arch, the *sikras* or towers surmounting the cells containing the images, and, lastly, by the peculiar grouping of many temples together on hill-tops. Prominent examples of Jaina architecture are found at Girnar in Gujerat, and at Mount Abu. The most flourishing epoch of the Dravidian style comprises the 16th, 17th, and even 18th centuries of our era. To this late period belong the great temples at Tanjore, Tiruvalur, etc. The distinctive parts of a Dravidian temple are the *vimana* or temple proper, with storied pyramidal roof; the *mantapas* or porches, covering the door which leads to the cell; the *gopuras* or gate-pyramids, in the quadrangular enclosures surrounding the vimanas; and the *choultries* or pillared halls, used for various purposes. The

INDIAN BEAN — INDIAN MUTINY

general characteristics of a Dravidian temple of the first class are the storied pyramidal towers, the hall of 1,000 columns, the bold cornice with double flexure, the detached shafts, the richly carved stylobate, and the large tanks with flights of stone steps. The Chalukyan style, so named from a dynasty which rose in the 6th century in what is now Mysore and the Nizam's Territory, reached its perfection in Mysore from the 11th to the 14th century. The characteristic features are the open porch, the straight-lined, conical-shaped tower, the star-shaped temple, and the basement terrace of stone.

The Indian-Saracenic style is a general name for a number of somewhat varying styles, the result of the mixture of Saracenic principles of architecture, brought with them by the Mohammedan conquerors of India, and the distinctive architectural features of the different localities where they settled. Under the Mogul emperors in the 16th century were erected some most magnificent buildings, such as the tomb of Humayun Shah at Old Delhi; that of Akbar at Secundra; the palaces of Shah Jehan at Agra and Delhi; and the Taj Mahal, built by the same monarch at Agra. (See AGRA.) The Moslem architecture of India contrasts with the native Indian styles in its use of the radiating arch, in the superior simplicity and grandeur of its style—its flat ornamentation not interfering with the lines of true architectural construction. A characteristic feature also is its fine conventionalism of vegetable forms for decoration and tracery. See Moslem Architecture under ARCHITECTURE.

Indian Bean, a catalpa (q.v.); specifically the large southern tree (*Catalpa catalpa*), now planted as a shade or ornamental tree all over the country on account of the beauty of its masses of spring flowers and the quaint appearance in autumn of its long, bean-pod-like fruit.

Indian Bible, the first Indian translation of the Bible in the New England colonies. This translation was made in 1663 by John Eliot, "The Apostle to the North American Indians." It was in the dialect of the Naticks, a Massachusetts tribe of the Algonquins. A second revised and corrected edition was printed in 1685, only 12 copies of which are known to exist. An edition with notes by P. S. Du Poneau, and an introduction by J. Pickering, was published in Boston in 1822. When the original edition was issued, 20 copies were ordered to be sent to England. A copy of the edition of 1663, with the Epistle Dedication, was sold in 1882 for \$2,900.

Indian Bread-root, a plant of the genus *Psoralea*; the "large" was *P. esculenta*; the "small" *P. hypogaea*. See BREAD-ROOT.

Indian Corn. See MAIZE.

Indian Fig. See PRICKLY PEAR.

Indian Head, (1) the highest point of the Palisades, 550 feet; so called because it resembles somewhat the head of an Indian. It is in the northeastern part of New Jersey, on the Hudson and opposite Hastings. (2) The name of a village in Fayette County, Pa. (3) A small town in Maryland, on the Potomac River, below Washington, the seat of a naval station.

Indian Hemp. See CANADA HEMP; APOCYANACEAE.

Indian Hippo, an American plant. See BOWMAN'S ROOT.

Indian Humped Cattle, a species of East Indian oxen (*Bos indicus*), now known only in the domesticated state, distinguished by a high fatty hump on the withers, by the prevalent ashy gray color, large drooping ears, enormous dewlap and several structural peculiarities. They vary in size from those as large as a European ox to the smallness of a half-grown calf. They form the working cattle and draft animals all over India and eastward more or less locally to China. They are venerated by the more pious sects of Hindus, especially in the persons of certain privileged bulls, called Brahma or Brahminy bulls, which wander about the bazaars of cities unharmed and uncheked in their depredations upon market produce.

Humped cattle are known in Madagascar, and in Abyssinia, and it has been suggested that the species was originally African. The Abyssinian form is a large animal with huge horns called "galla ox" or sunga. These animals seem to thrive only in hot countries, and have never been found profitable outside of their present range.

Indian Language and Literature. See INDIA.

Indian Mutiny. The British occupation of India had been largely aided by native troops called Sepoys, who were enrolled under British officers in the service of the East India Company. At the close of Lord Dalhousie's sway in 1856, when the whole of India seemed to have been either reduced directly under British rule, or if retaining its native princes to have placed itself under British protection, the Sepoy mutiny, a contingency for which the government ought not to have been altogether unprepared, occurred. Previous symptoms of disaffection had not been wanting. Mutiny had on several occasions broken out in the native army, in a way to indicate how easily through causes which Europeans, from their defective sympathy with native thought and feeling, could not anticipate, these troops might be alienated; but, on the other hand, the general fidelity of the Sepoys merited confidence, and this feeling prevailed over any grounds of suspicion which might have been formed from isolated occurrences. The Sepoys in Bengal were mostly either Mohammedans, or Hindus of the Brahmanical or military castes. The recent annexations had alarmed the native chiefs, while the fanatical Hindus had been deeply offended by reforms, including the successive abolition of various rites of their worship. Two European regiments had been drafted off for the Crimean war, and had not been replaced. Others had been sent to Burma, and in the beginning of 1857 fresh regiments were despatched to Persia, so that only eighteen regiments were left in all Northern India, of which nine were in the Panjab. In Oudh, where, from its recent annexation, disaffection was rife, there was only one British regiment, and Delhi and Allahabad, the two chief arsenals, were guarded by native troops. To add to these favorable cir-

INDIAN MUTINY

cumstances a Hindu devotee had prophesied the termination of British rule at 100 years after the battle of Plassey. A slight incident sufficed to give point and direction to a spirit of disaffection which so many circumstances tended to favor. At this time the Enfield rifle was introduced into the Bengal army. This rifle was loaded with a greased cartridge, the end of which required to be bitten off at the time of loading. By a natural inadvertence the authorities had neglected to consider how this seemingly trifling requirement might affect the easily excited sensitiveness of the Hindus in regard to caste, and this insignificant circumstance removed the last security against a united movement of disloyalty among the native troops, by establishing a bond of sympathy between the Mohammedans and Hindus. A report got abroad that the cartridges were to be soaked in cow and pork fat. The prejudices of Hindus and Mohammedans were thus equally involved, and as this rumor rapidly spread, the excited imagination of the Sepoys conceived a conspiracy on the part of the government to convert them forcibly to Christianity, by compelling them to violate the laws of their own religion. When this grievance was explained it was at once removed, the manufacture of greased cartridges at Dum dum was stopped, and the men were instructed to grease them themselves with materials procured at the bazaars. Suspicion once aroused, however, was not to be allayed, and easily found a new object of contention. The paper of the new cartridges was glazed, and it was again alleged that grease was used in its manufacture. The spirit of disaffection became too deep-rooted for any measures of conciliation. Conferences among the disaffected gave rise to ambitious schemes, and the original grievances became a pretext in the hands of unscrupulous leaders, whose excesses debarred them even from the plea of patriotism, to extirpate the British power in India. On 26 February the first overt act of mutiny took place at Berhampur, when a regiment refused to receive their cartridges. Another dangerous outbreak took place at Barrackpur on 29 March. The arrival of a British regiment from Burma and the disbandment of the disaffected regiments was thought to have ended the trouble, but it soon became evident that disaffection, which had only wanted an occasion, was spreading rapidly not only among the Sepoys, but among the Hindus generally. Another outbreak took place on 2 May, near Lucknow, when a regiment of cavalry were, by some oversight of the government's instructions, ordered to bite their cartridges. Sir Henry Lawrence succeeded by a show of force in disarming it. A more formidable outbreak occurred about the same time at Meerut, 35 miles northeast of Delhi, when the mutineers, with the assistance of the native inhabitants, indiscriminately massacred the Europeans and escaped to Delhi. The advance-guard of the mutineers reached Delhi on 11 May, and at once entered the city, where they were assisted by the king's servants in massacring the Europeans. The native troops cantoned outside the city in the meantime joined the main body of the mutineers, and assisted in massacring their European officers. About 50 Europeans sought refuge in the palace, and placed themselves

under the protection of the king, who had placed himself on the throne of the Moguls. These after some days were coolly murdered in an open court in presence of a general concourse of spectators, conspicuous among whom was Mirza Mogul, the king's eldest son, who had assumed the title of commander-in-chief. The magazine at Delhi had been blown up by its defenders; but the explosion was only partial, and most of its contents fell into the hands of the mutineers. European troops were now summoned from all quarters. Several regiments were detached from an expedition which was proceeding under Lord Elgin to China, and the Persian war having been concluded, the troops engaged there were immediately recalled. When intelligence of these events reached the Panjab the mutinous spirit which prevailed among the large body of Hindustani troops there was promptly subdued by disarmament. The Sikhs, though the Panjab had been so recently annexed, continued faithful. But the revolt had spread rapidly elsewhere, and British authority was almost extinct throughout the Bengal Presidency. Everywhere the mutiny was attended with savage excesses—women were outraged, and Europeans, without distinction of age or sex, barbarously murdered. Sir Hugh Wheeler, at Cawnpore, was betrayed by Nana Sahib, maharajah of Bithur, who, after offering aid, took the mutineers into his pay, and raising the Mahratta standard, besieged Cawnpore. The siege, or rather bombardment, lasted from 7-24 June, when a capitulation was agreed to, on a sworn promise of Nana Sahib to allow the garrison to retire to Allahabad. But as the embarkation was proceeding the boats were attacked by the Nana's troops, and the men indiscriminately massacred. The women and children were for the meantime made prisoners. Sir Henry Lawrence was besieged in Lucknow, where he died on 4 July from a wound received in a sortie.

Meanwhile mutineers had been converging on Delhi, and British reinforcements were hastening to the besieging camp on the ridge above the city. After protracted operations and repeated reinforcements on both sides Delhi was taken by assault, 14-20 September. Sir Henry Havelock, who had been engaged in the Persian campaign, had arrived in Calcutta, and immediately set out for Allahabad, to commence operations for the relief of Lucknow and Cawnpore. While his force was victoriously advancing on Cawnpore Nana Sahib, on 15 July barbarously massacred his prisoners, consisting of 210 women and children. Havelock was succeeded in the command at Lucknow by Sir James Outram, who held it till relieved by Sir Colin Campbell, on 17 November. At first it was feared that the mutiny might extend to the Bombay and Madras presidencies, and from this cause and the occupation of the troops in Bengal the mutineers had been left unchecked in Central India. At length columns organized in these presidencies entered Central India, and were united under Sir Hugh Rose. By the operations of these commanders the brave Rani of Jhansi, who died fighting at the head of her troops, was defeated, and Tantia Topi whose military capacity had prolonged Nana Sahib's resistance, was captured and the mutiny was

INDIAN OCEAN

finally suppressed. The war was substantially closed by June 1858, although the complete pacification of Oudh was not effected till the end of the year. See INDIA, EAST INDIA COMPANIES. Consult: Malleson, 'History of the Indian Mutiny' (1897).

Indian Ocean, that body of water which has Asia on the north, the East Indian Islands, Nicobar and the Andaman Islands, Australia and Tasmania on the east, Africa on the west, and the Antarctic continent on the south. The Cape of Good Hope, and the southern extremity of Tasmania may be considered its extreme limits from east to west. Its length from north to south somewhat exceeds 6,500 miles, its breadth varies from 6,000 to 4,000 miles. Its gulfs are the Red Sea, the Gulf of Aden, the Persian Gulf, the Gulf of Oman, the Arabian Sea, the Bay of Bengal, and the Great Australian Bight. Its islands are Ceylon, Madagascar, the Laccadives, Maldives, Socotra, Andamans, Nicobar, Mauritius, Bourbon, Kerguelen's Land, etc. Rocks and coral reefs render navigation dangerous. The Ganges, Brahmaputra, Irrawaddy, Indus, Euphrates, Gadaravi, empty into the Indian Ocean. The southeast trade-wind blows between the 10th and 28th parallels of south latitude from April to October, after which date its limits are contracted; south of these are the northwest winds, which prevail almost in the same latitude, in the Atlantic and Pacific. The monsoons are mainly to be found in the north, from the continent of Asia to about lat. 8° S., and from the Mozambique Channel on the west to the western shores of Australia and the sea of China. They blow for six months, changing about the equinoxes. North of the equator the northeast monsoon prevails from October to April, the southwest from April to October; while south of that the northwest monsoon blows while the northeast is blowing on the north side, and the southeast prevails during the time of the southwest monsoon north of the equator. In the hot season, likewise, when the southeast trade-wind recedes south, the northwest monsoon flows between the equator and the 12th south parallel. The hurricanes of this ocean usually range between lat. 9° and 31° S., extending from Madagascar to the Island of Timor. They usually come from the northeast, and travel southwest and south, returning again east. Their season is from December to April.

According to the most recent soundings the mean depth of the Indian Ocean is 2,300 fathoms, or somewhat greater than that of the Atlantic. The greatest depths are in the eastern part to the south of the equator, where it is estimated that there are fully 50,000 square miles with a depth of over 3,000 fathoms. Over 13,000,000 square miles lie between the depths of 2,000 and 3,000 fathoms.

The area of land draining into the Indian Ocean is estimated at 6,813,600 square miles, and the rainfall on this land amounts to 4,379 cubic miles of water annually. The rivers flowing from the Asiatic continent are by far the most important, and they carry a vast amount of detritus into the Bay of Bengal and Arabian Sea, these forming immense deposits of blue mud. Along the African coasts, in depths from

100 to 1,000 fathoms, there are glauconitic sands and muds, and on these as well as other coasts, coral muds and sands, and blue and green muds in the shallower depths. In the deeper parts of the ocean, far from land, there are deposits of red clay, radiolarian-ooze, and globigerina-ooze. Toward the Antarctic continent the ocean bed is covered with a diatom-ooze.

The temperature of the surface waters varies much in different parts of the ocean, at different seasons, and under the influence of different winds. In tropical regions the temperature usually varies from 70° to 80° F., and the yearly range is 7° or 8° F. Off the Cape of Good Hope and Cape Guardafui, the annual range may be from 20° to 30° F. Sudden changes of temperature are often noticed off Cape Guardafui when the wind blows off shore. The cold and deep water is thus drawn up along the coast to take the place of the warm surface water which is driven east by the wind.

The temperature of the water at the bottom is very uniform and subject to little, if any, annual variation. In the Bay of Bengal and Arabian Sea temperatures of 33.7° F. and 34.2° F. have been recorded; these are only very slightly higher than those recorded by the Challenger in lat. 50° S. It is certain, therefore, that this deep cold water is slowly drawn into the Indian Ocean from the Antarctic to supply the place of the warm surface currents that are driven south by the winds.

The currents of the Indian Ocean are less constant than in the other oceans, being largely controlled by the monsoons. Some characteristic coral atolls and islands are found toward the central part, such as the great Maldivian group, the Chagos, Diego Garcia, and the Cocos Islands. The tropical shores are generally skirted by fringing and barrier reefs. Christmas Island is coral formation, while St. Paul's, Mauritius, Rodriguez, and others are of volcanic origin, and Madagascar, Ceylon, and Socotra, continental islands.

The Indian Ocean was little known to the ancients. The first Europeans who explored it seem to have been the Phoenicians, who in the 7th century B.C. held the thalassocracy, or marine domination of the Mediterranean. Necho, an Egyptian monarch who flourished about 610 B.C., is reported by Herodotus to have sent some of his vessels, manned by Phoenicians, into the Indian Ocean, then known as the Erythraean Sea, to circumnavigate Africa. This they did, starting from the Arabian Gulf and regaining Europe by the Columns of Hercules. In the 6th century B.C. this sea was traversed by Hanno, a Phoenician admiral of Carthage. There is still extant his account of the voyage which is translated into Greek under the title 'Hanno's Voyage of Circumnavigation.' The Greek historian Arrian has given us an account of the coasting voyage of Nearchus, one of Alexander's generals, from the Indus to the mouth of the Tigris and Euphrates.

Hippalus, an Egyptian navigator who flourished about the beginning of the Christian era, was the first to observe the regular monsoons of the Indian Ocean, and to profit by them. In the 9th century the Arabs made frequent voyages across the Indian Ocean. In 1486 the Portuguese rounded the Cape of Good Hope,

INDIAN PAINT—INDIAN SUMMER

and in 1498 Vasco da Gama reached the coasts of India by the same route. In 1521 a ship of Magellan's squadron crossed the Indian Ocean in completing the first circumnavigation of the world.

Indian Paint, the name of two American plants: (1) the golden seal (q.v.) or orange-root, which furnishes a yellow color; and (2) the bloodroot. (See *SANGUINARIA*.)

Indian Paint-brush. See *PAINTED CUP*.

Indian Physic, an American plant. See *BOWMAN'S ROOT*.

Indian Pipe, or **Corpse-plant**, a smooth, waxy-looking, fleshy herb (*Monotropa uniflora*), of the order *Ericaceæ*, widely distributed in dark, rich woods almost throughout North America. It is said to derive some of its food from the roots of other plants, but much is obtained from decaying vegetable matter. From a matted mass of fibrous rootlets the white scaly, but not leafy, stems rise to a height of perhaps eight inches, and bear solitary, nodding, white, inodorous flowers during summer, followed by erect many-seeded fruits.

Indian Races. The numerous peoples of India belong to several distinct groups or families, speaking numerous dialects founded on two or three distinct stocks which are much blended by the intercourse of the different peoples with each other. Previous to the Mohammedan ascendancy the dominant race were the Hindus, whose language is spread in various dialects over a great part of India, but who were not the aboriginal inhabitants nor even the first invaders. From the northwest of India, through Kashmir and down the valley of the Indus, and from Tibet through the passes of the Himalayas, the inhabitants of northern Asia have from a very early period migrated southward to the milder and more fertile plains of India. Two great successions of these invasions are recognized as having taken place before the period of authentic history. The first immigrants, of dubious ethnological connections, but commonly known as the Tamil races, appear to have overspread the entire peninsula. Following them the Sanskrit-speaking peoples, called the Hindus, of Aryan speech, dispossessed the Tamil races, and superseded their language in the whole of India north of the Narbada. The Hindus subsequently descended into the peninsula and penetrated as far as Cape Comorin; but though their influence on the languages of Southern India was considerable in the way of introducing new terms, the grammar and construction of the Tamil languages maintained their place in the districts south of the Narbada. Two great groups of languages were thus spread over India, which were further modified by the Mohammedan invasion. The native tribes were not exterminated by these invasions, but are still to be found under various names, as Bhils, Catties, Coolies, Gonds, etc., inhabiting the fastnesses of the mountain ranges in Bengal, the Vindhya and Satpura Mountains, the Ghâts, etc. The hill tribes and other aborigines in all India are estimated at 70,000,000. The leading religion is Brahmanism, the professed creed of the majority of the Hindus and the religion most distinctive of India. It reckoned 207,000,000 adherents in 1901. Large numbers in the north and northwest are Mohammedans (about 62,-

500,000). Buddhists number about 9,500,000; Parsees or Fire-worshippers 95,000; Sikhs 2,200,000. Among the Hindus the caste system still prevails. European missionaries have long been active, but only a mere fraction of the people are as yet Christians (2,284,380). Education is now making good progress, schools and colleges of all kinds having been established throughout the country. The pupils, however, only number about 4,000,000 in all. There are universities at Calcutta, Bombay, and Madras, besides other two at Lahore and Allahabad.

Indian Red, an impure oxide of iron, used as a pigment by painters. It was originally imported from India, but is now chiefly prepared by roasting ferrous sulphate. The sulphuric acid is expelled by the heat, and the red oxid of iron remains behind. It is very permanent, and the color varies from purplish to a yellowish red.

Indian River, an important stream in the eastern part of Florida, in Brevard and Volusia counties. It connects with the Halifax River at Titusville and extends 100 miles southeast to the ocean at Indian Inlet. Its width varies from 300 feet to 3 miles and it is navigable for vessels drawing five feet. The Indian River is famous for the excellent oranges grown along its banks.

Indian Schools, in the United States, are schools specially established either by private or denominational means or by the national government, for the education of children and youth of the Indian population of this country. For particulars concerning these schools see *INDIAN AFFAIRS; INDIAN EDUCATION OF THE*.

Indian Shot. See *CANNA*.

Indian Summer, the name given to a period of mild summer weather which generally occurs toward the end of autumn. The term first made its appearance in the last decade of the 18th century. During the next decade the phrase was "second summer." This indicates that the spell of weather known by this name was not generally noticed much before 1800. The term Indian summer became established about 20 years after its first appearance, which was in western Pennsylvania, and spread to New England by 1798, to New York by 1799, to Canada by 1821, and to England by 1830. The term is, then, not an Americanism; to write in praise of Indian summer is now a literary convention of three continents.

It is by no means easy to account for the origin of the term. The principal characteristics of the season which it describes are haziness, smokiness, and high temperature. Some explanations of the origin of the term are (1) that the Indians predicted such spells of weather; (2) that the smokiness was produced by Indian fires; (3) that this was the last season of Indian attacks on the settlements of the whites; (4) that the season partook of the Indian character of deceptiveness; (5) that the name was given because one of the seasons of East India was similar in character. Horace Walpole used the term in 1778, not in reference to America, but in relation to weather in the tropics. "Squaw winter" was a name for the spell of cold weather preceding the Indian summer, and perhaps the key to the nomenclature is to be sought in this latter term.

INDIAN TERRITORY

Indian Territory, an organized body of land in the southwest centre of the United States, occupied by Indian allotments and reservations; not a "Territory" in the official sense, as it has no common local government, head, or capital, and sends no delegates to Congress. It lies between Kansas north and Texas south, Arkansas and a corner of Missouri east, and Oklahoma (till recently its own western half) west. It is about 250 miles north to south, and from 75 to 200 east and west. Area, 31,400 square miles, of which 400 are water.

The topography of the district is not yet fully studied, as Indians do not make surveys, and till less than a decade ago the government had no motive but a scientific one for undertaking them. Hence the interior was nearly as little known as central Africa, and as much misunderstood. Even yet, nearly every reference book describes the entire surface as "flat" or "gently rolling," and mostly prairie. But the government survey authorized in 1894, when the reduction to civilized conditions was undertaken, found it to be one fourth mountainous plateau, and two thirds woodland well distributed, mainly through the east and southwest portions. The prairie section is a continuation of the Kansas plains, and occupies most of the Cherokee district north of the Arkansas, and the Creek triangle between the Arkansas and Canadian, with about a fourth of the western half below the Canadian, the rest being timber land. In the extreme northeast is a rugged plateau cut by streams with a southward trend, west of which is a rolling plain with some hills. South of this the Ozark mountain chain, entering from Arkansas, stretches from northeast to southwest across the Territory, with a gradual declension; from about 2,500 feet high near the Arkansas line, they sink to about 1,000 feet in the centre. Their more pronounced elevations are termed the Boston, Poteau, Kiamichi, Sans Bois (treeless), Shawnee, etc. In the Chickasaw territory at the southwest, a set of low elevations from Tishomingo northwest, rising in the sharp spur called the Arbuckle Mountains, and again farther on in the Wichita Mountains of Oklahoma, connect the Ozarks with the outliers of the Rockies. The highest elevation in the Territory is about 3,000 feet above sea-level, the lowest 350. The timber north of the Canadian is mainly confined to a belt in the west, save for cottonwoods, elms, pecans, and a few other sorts along the streams; south of it the timber occupies much the greater portion, even in the west. The eastern half of the Territory is nearly all well wooded, the mountainous parts most heavily so; the woods besides the above are oak, largely in a belt from the Arkansas to the Red called the Cross Timbers (used only for fuel and railroad ties, not for construction), with valuable yellow pine and red cedar on the elevated grounds, and walnut in the bottoms.

The drainage belongs entirely to the Arkansas and Red River systems. The former, flowing across and cutting off a northern cantle, is joined east of the centre at Webber's Falls by the long Canadian, its main affluent, which forms nearly the median line of the Territory and its northern boundary with Oklahoma; and is further fed from the north by the Neosho and the Verdigris joining close together, and by the Illinois near the Canadian. The latter

has hardly any water-shed on the south. Nearly the whole southern half of the Territory is drained by the affluents of the Red, forming the entire boundary with Texas; the chief are the Washita in the southwest and the Kiamichi in the southeast.

Geology and Minerals.—Geologically, the Territory may be divided into four sections: (1) The Arbuckle-Wichita region, with an outlying granite field at Tishomingo. This contains coal measures on the north and asphalt on the south; the former is the chief mineral product of the Territory. For the year ending 30 June 1903, there were employed in coal mining 6,001 men and boys; there were in operation for the same year 280 coke ovens, producing 52,625 tons of coke; the coal tonnage for the same year was 3,243,692 tons. Large bituminous asphalt deposits occur in the Choctaw and Chickasaw Nations; these have been worked some, but owing to the want of railroad facilities, and the asphalt trust, the operators have not been encouraged with very great success. There are also sandstone and limestone as well as granite. (2) The Ozark system, Carboniferous and Silurian, containing zinc and lead. (3) The northern prairie, Carboniferous, with coal and large quantities of petroleum. (4) The southern plains cropping over from Texas, underlaid by the Cretaceous, with artesian strata, and sand and marl above. There are valuable gold and silver deposits from which Indians have long made all their trinkets, but they have kept the places secret, to prevent an influx of miners.

Fauna.—The characteristic species are the timber and prairie wolves, panthers and foxes, black bear, deer, prairie dogs, and some smaller game. The wild turkey is the most important bird.

Climate and Rainfall.—The Territory belongs to the southern division by temperature and to the middle one by precipitation. It has a mean winter temperature of 35° to 48°, and a summer one of 77° to 82°; while the rainfall, light in the north like western Kansas, is heavy in the southeast (52 inches), and steadily decreases to the west (about 35 inches at Fort Gibson and 30 in the southwest). But hardly anywhere is it too scant for favorable agricultural conditions.

Agriculture.—Scarcely any region of the United States has greater natural advantages in fertile soil and plentiful water supply. With the opening of the Territory to white settlement and ownership, a vast increase in production will be effected. Until within the present year (1904) the word "ownership," as applied to tenures in the Indian Territory, had a peculiar meaning. To protect Indian interests, white men (except licensed traders and those made citizens by marriage to Indian wives in accordance with the laws of the tribe, or adopted into the tribe by tribal legislature) could not hold land, except as tenants of Indian landlords. The fee to the land in all cases was in the Indian tribes, and even the Indian citizen had only in a sense an occupancy right, owning the improvements absolutely, and cultivating the land practically as a fee simple owner, but always subject to future allotment among all the members of the tribe.

Within the past few years, agreements have been made between the United States and each of the five civilized tribes by which the lands of such tribes are being allotted in severalty to

INDIAN TERRITORY

the citizens thereof, with the power of alienation in most of the nations, under certain restrictions, of all, except a certain amount reserved as a homestead, which, in some cases, is inalienable during the life of the allottee, and in others for 21 years, if the allottee lives so long.

In the Creek Nation, 120 acres of an allotment can at present be alienated with the consent of the secretary of the interior, which is being rapidly accomplished, under the rules and regulations prescribed by him, and the allotments are being bought by whites, who are either occupying them themselves or leasing them to other whites. The real Indian, as a rule, is not much of a farmer, and, as the amount granted to an Indian family is generally greater than the head can utilize or cares to utilize, the remainder is leased to some white farmer or cattleman. The whites farm a large proportion of the farms at present. In the year 1890, of the 35,451 farms cultivated by whites only 3,475 were owned by them.

These allotments to the Indians vary in the different tribes. A Choctaw and Chickasaw allotment is 320 acres of average allotable land, and of this the homestead consists of 160 acres of average allotable land, the latter inalienable during the lifetime of the allottee, not exceeding 21 years from the date of the certificate of allotment; the remainder of the land is alienable after issuance of patent, as follows: one fourth in acreage in one year, one fourth in acreage in three years, and the balance in five years; in each case from date of patent.

The Creek allotment is 160 acres, 120 of which is inalienable before the expiration of five years from the 8th day of August 1903, except with the approval of the secretary of the interior; the balance of 40 acres constitutes a homestead, which is inalienable for 21 years, unless the allottee sooner die, in which event the homestead remains for the use and benefit of children born too late to receive an allotment; but, if there be no such issue, then the allottee may dispose of his homestead by will free from restrictions, and, if this be not done, it descends to his heirs free from any limitations.

In all the above cases, as well as in the Seminole Nation, where the land was divided equally between all the members of the tribe, the allottee had the right to select his allotment so as to include any improvements owned by him at the time. At present the allottees can rent their allotments for one year for grazing purposes, and five years for agricultural purposes, and longer in some cases with the consent of the secretary of the interior. Mineral leases may also be made up to 15 years with the consent of the secretary of the interior.

The productions might easily be of the greatest variety in this warm moist region, but the conditions of tenure hitherto did not encourage tenants to diversify crops or improve the condition of farms to revert to Indian owners. The great crop at present is corn, of which in 1900, 30,709,470 bushels were raised; 1,486,820 of wheat, and 1,102,200 of oats were reported. The territory is well within the cotton belt, and 154,850 bales were shipped in 1900. The other products of note were about \$1,000,000 of vegetables and fruits. Stock-raising is largely carried on; the value of domestic animals in 1900 exceeded \$40,000,000, and included 110,687 dairy cows, 275,000 horses, mules and asses, 17,000

sheep, 10,500 goats and 650,000 swine. It has been known to many that there was a large quantity of oil and gas in this country, but owing to the lack of laws permitting leases and development in the Indian lands, nothing was done until within the last 18 months. The change in the laws, however, has permitted a great deal of development work in some of the towns as well as on outside allotments, and the production is proving very satisfactory to the lessees, as well as the lessors. The field thus far developed is in the northern portion of the Cherokee Nation and the border of the Creek Nation.

Manufacturing.—The manufactures till recently have been mostly confined to the Indian hand-made blankets, shawls, baskets, and trinkets. But within the decade a considerable genuine manufacture by whites has arisen. With only 20 establishments in 1890, there were 789 in 1900; the capital had grown from \$204,329 to \$2,624,265, the wage-earners from 167 to 1,714, the value of products from \$248,932 to \$3,892,181. The one great industry, nearly a third of the total products, was flour and grist milling; next greatest, toward half a million each, were cotton-seed oil and cake; and lumber, saddlery and harness, and car-shop work were also noted.

Railroads.—There are about 1,800 miles of railroad in the Territory: Several great lines cross it, giving the facilities for the vast business growth. The main lines are the Frisco System (St. L. and San F.), the St. Louis, Iron Mountain & Southern, the Missouri, Kansas & Texas, the Choctaw, Oklahoma & Gulf, the Atchison, Topeka & Santa Fe, and the Ft. Smith & Western.

Banks.—In 1902 there were 69 national banks, with capital of \$2,779,000, deposits of \$5,896,000, cash and other resources \$548,000, and loans and discounts of \$7,277,000. There were also 20 private banks, having capital of \$203,975, deposits of \$495,810, cash of \$56,354 and loans and discounts of \$602,676.

Population.—The total population in 1890 was 180,882; in 1900, 392,060, the increase being all white. The real Indian population had probably somewhat decreased, though it showed on the face a slight increase, from 51,279 to 52,500. But the word "Indian" is misleading: for legal purposes and tribal recognition, any one is an Indian who has even 1-64 or in fact any degree of Indian blood in him; and probably two thirds of the so-called Indians are mixtures of various complexities and elements. The negroes, numbering 36,853, are for the most part the former slaves of the Indians, to whom the United States after the war forced the tribes to grant citizenship and a share of the tribal lands and bounties, or their descendants. These two and the vast white population—married and adopted, leaseholders and tenant farmers, hired farm laborers, business men with permits, coal and railroad company employees, etc.—were distributed among the chief districts as follows (besides 27 Chinese):

Chickasaw Nation, 124,306 whites, 9,066 negroes, 5,872 "Indians." Cherokee Nation, 66,951 whites, 9,162 negroes, 25,639 Indians. Choctaw Nation, 79,332 whites, 10,123 negroes, 10,321 Indians. Seminole Nation, 1,143 whites, 981 negroes, 1,662 Indians. The other reservations—Modoc, Ottawa, Peoria, Quapaw, Seneca, Shawnee, Wyandotte—had 5,762 whites and

INDIAN TOBACCO — INDIAN TURNIP

1,043 Indians. The concentration of whites in the Chickasaw district had made it the industrial leader of the territory.

The towns which grew there formerly had a peculiar status. They were "white" towns with white men occupying the buildings they had erected, and doing business insecurely, without legal title, but the ostensible owners of the ground were the Indians. The so-called Curtis Bill and the various agreements made with the tribes above referred to have changed this condition, and made it possible for the white man, or any other occupants of towns in the Indian Territory to purchase lots under the various provisions of these bills upon which they owned houses or other valuable improvements. The result is that all the larger towns have been platted, surveyed and sold to the occupants, so that the Indian titles have become almost entirely extinguished. Within a year or eighteen months every town within the limits of the Indian Territory will have been so platted and sold. The changes are so great and constant that statistics are nearly as useless as in a new mining district, but it may be said that the present chief towns are Ardmore, and Chickasha, in the Chickasaw Nation, South McAlister in Choctaw Nation, and Muskogee in the Creek Nation, is the handsomest town in the Territory, with good public schools, churches and four colleges of the four leading denominations — Baptist, Methodist, Presbyterian, and Roman Catholic. These towns now have a population approaching 10,000 each and there are over 20 others with over 1,000. The oldest white settlement is Vinita in Cherokee; the oldest in the southeast is Caddo; the best known has always been Tahlequah, for some generations the capital of the Cherokee Nation.

Internal Conditions and History.—The Territory was part of the Louisiana Purchase. Early in the 19th century many of the Southern Indians, their old hunting grounds invaded by the whites, removed to this virgin forest. In 1832 it was fixed on by the national government as a place for the tribes whom agreements with the Southern States had bound us to deport, and in 1834 special reservations were set apart. The Five Civilized Tribes, as they are called, established governments on the civilized model, with elected legislature, council and governor, courts and schools and responsible financial management, and even newspapers in the Cherokee tongue, with Sequoyah's famous alphabet. But the vast enclave of nearly 70,000 square miles in the heart of a swelling settlement could not be maintained, and the Indians from some constitutional blight do not grow to fill their districts. In 1866 some 5,500,000 acres were purchased of the Indians in the present Oklahoma; on 22 April 1889 over 3,000,000 acres were thrown open to settlement; on 2 May 1890 this and other territory was formed into Oklahoma. Meantime the old system in the eastern part was going to wreck, not so much from the white immigration, following the railroads which began to cross it, as from internal development which was making the primal object of the system a mockery. It was designed to protect the half-helpless Indian from white greed till he could stand on his own feet; in fact, the half-breeds and the intermarried whites were rapidly appropriating everything to themselves, while the full-blood was "crowded out upon the moun-

tain and unproductive land, to take care of himself as best he could." (Dawes Commission.) The tribal governments were under control of these governments and were "recklessly leasing the community lands to cattlemen and coal companies" (Hinton), to railroads, oil and lumber companies, etc. The government, therefore, under the lead of ex-Senator Henry L. Dawes of Massachusetts, set about negotiations to break up the tribal governments, and turn the Territory into a set of ordinary civilized communities with ownership in severalty, protecting the Indian for a time by restraining his liberty of alienation. The Dawes Commission of 1893 began this work; in 1897 the United States extended its judicial power over the district; in 1898 the Curtis Act carried out the work, providing for the enrollment of citizens for allotment of lands, for laying out town sites and incorporating towns with power to elect officers and tax themselves for schools, etc., and giving the President a veto power over the tribal legislatures. The arrangements vary with the different tribes; the Seminoles continue their government after a fashion for the present, the Choctaws and Chickasaws with some modifications till 4 March 1906. The present government consists in reality of four federal judges or one court of appeals and four district courts, with 20 commissioners acting as petty courts and justices of the peace, and a resident Indian Inspector. The statutory code is in the main that of Arkansas.

The educational situation has been a part of the anomalous position of all social matters. The tribes maintained schools and admitted white children on payment of a fee; and the missionaries have operated others. But all were very insufficient, and the tribal schools, once the best of the vicinity, have not kept their quality. The Curtis Act of 1898 for the first time provided a public-school system, in cities and towns, and power of towns to levy taxes for them. In 1900 it was estimated that 50,000 white children were deprived of school advantages. Of academic schools, some claiming collegiate rank, there are good ones in each nation; these have sent many pupils to Eastern colleges. By act of 19 May 1902 municipalities of 2,000 or more inhabitants may issue bonds up to 10 per cent of their assessed valuation for school buildings, sewers, and waterworks on a two-thirds vote and with a 20-year sinking fund. Pop (1900) 392,062; (1903) fully 500,000. Consult: "Report of the Dawes Commission" (1903); Curtis Act in U. S. Statutes. WILLIAM T HUTCHINGS,
Muskogee, Indian Territory.

Indian or Wild Tobacco, one of the North American lobelias (*Lobelia inflata*), also called asthma-weed and gag-plant,—a tall plant with small light blue flowers quite overshadowed by numerous thin, oval, or obovate dentate leaves; the plant branches as a panicle, is pubescent and the pod is inflated. Its leaves have an acrid taste, and are, as Gray says, "poisonous and a quack medicine"; they were dried by the Indians as a substitute for smoking tobacco, or to mix with it, for the sake of their narcotic properties. The dried flowers still have a place in *materia medica*. It grows in dry fields and thickets through North America. Compare KINNICKINICK.

Indian Turnip. See JACK-IN-THE-PULPIT.

INDIAN YELLOW—INDIANA

Indian Yellow, known in commerce as **PUREE**, a pigment of unknown origin which is exported from India, China and probably from Arabia. It comes in the shape of balls, which are outside of a brown tint, and inside of a brilliant yellow. It has the odor of urine, musk or castoreum, is soluble in water or alcohol, and an essential element in its composition is carbonate of euranthin. It is used in India for house decoration, and is valued by artists all over the world as a dazzling pigment.

Indiana ("The Hoosier State"), a north-central State of the United States (No. 19 in order of admission) bounded north by Michigan, south by Kentucky, east by Ohio, west by Illinois; extreme length 276 miles, extreme breadth 177 miles; area (No. 34 in U. S.) 36,350 square miles, 440 water; pop. 1900 (No. 8 in U. S.) 2,516,402, or 70.1 to the square mile. (No. 11 in density.) The State boundary in Lake Michigan is an east and west line 10 miles north of the extreme southern point of the Lake. The Ohio River runs along the southern boundary, but, by a provision of the Virginia cession of Northwest Territory, Indiana extends only to low-water mark on the north bank of the Ohio. In consequence all islands in the Ohio belong to Kentucky, the Supreme Court having recently held this as to Green River Island (*Indiana v. Kentucky*, 136 U. S.) which, although an island at the time of the cession, became connected with the Indiana shore by alluvial deposits, and had been governed and taxed as part of Indiana for many years.

Topography.—The surface of the State is comparatively level, the highest point, in Randolph County, in the centre of the eastern tier of counties, being estimated at 1,285 feet above sea-level, and the lowest, at the southwest corner of the State, being 313 feet above sea-level. The Ohio at the southeast corner of the State is 436 feet above sea-level, and Lake Michigan at the northwest corner is 585 feet above sea-level. From the table-land of the east central part of the State, and western Ohio, radiate low water-sheds separating the drainage basins of Indiana. The northern part of the State is quite flat, the central part slightly rolling, and the southern part rather hilly on account of the valleys cut out by water. There are no mountains, and no large lakes, but there are hundreds of small lakes, chiefly in the northern part of the State.

River Systems.—The southern parts of the State are drained to the Ohio River by the Whitewater and smaller tributaries. The central part of the State—about four fifths of its area—is drained by the Wabash and its tributaries, the most important of which are the White, Tippecanoe, Eel, Salamonie and Mississinewa rivers, and Wild Cat Creek. The northeastern corner of the State is drained by the St. Joseph's and St. Mary's rivers; these unite at Ft. Wayne to form the Maumee, which flows into Lake Erie. The extreme northern part of the State is drained by another St. Joseph's, the Calumet, and smaller streams, into Lake Michigan. A part of the northwestern section is drained by the Kankakee and its tributaries to the Illinois River. The Wabash is navigated to a limited extent, by small boats, as high as Terre Haute, and also the lower part of White

River. The remaining streams are not navigable.

Climate.—The climate of Indiana is mild, ranging from an average of 31° F. in the winter months to an average of 76° in summer. The mean temperature is 53°. The average annual rainfall is 43 inches, that in the southern part of the State being slightly in excess of that in the northern part. Serious droughts and destructive storms are rare. In earlier years parts of the State were malarial, but with the clearing of the forests and the drainage of lands this condition has almost wholly disappeared.

Geology.—The earliest geological formation that outcrops in Indiana is the Hudson and Trenton limestone, of the Silurian Age, which appears in the southeastern corner of the State, throughout the Whitewater Valley and the adjacent region. West of this is a belt of Niagara limestone, which broadens at the north and extends entirely across the State, covering all of a dozen counties and large parts of as many more. On the west of this, and also extending to the State line on the north, are belts of Hamilton limestone and sandstone of the Devonian Age. The remainder of the State—the southwestern corner and a broad belt to the north reaching beyond the Wabash—is of the subcarboniferous and carboniferous formations. The northern and central parts of the State are covered by glacial drift, which in some regions is of a depth of 400 feet.

Soils, Agriculture and Forests.—The soil of the State varies in character, but for the most part is fertile. Originally the southern part of the State, and as far north as the Wabash, was covered with a very heavy growth of forest, mostly of hardwood trees. North of this were low prairies interspersed with sand ridges and dotted with hundreds of small lakes. This region is now found very productive of cucumbers, melons and small fruits in the sandy parts. The richest lands are the alluvial valleys of the streams and the drained prairies. The forests have so far disappeared that the State is now encouraging tree planting. Agriculture is the chief industry of the State, the value of farm products in 1899 being reported at \$204,450,196. The chief agricultural products were corn, 178,067,070 bushels, wheat 34,986,280 bushels, oats 34,565,070 bushels, potatoes 6,209,080 bushels, hay 3,470,378 tons. The value of animal products was \$81,947,922, of forest products \$5,235,459, of orchard products \$3,166,338, of dairy products \$15,739,594. The value of the poultry raised in 1899 was \$8,172,993, and of the eggs produced \$7,441,944.

Minerals and Mining Industries.—About one fifth of the surface of Indiana is underlaid by coal, workable veins having been found in 19 counties. There are at least 7 distinct veins of workable thickness, varying from 3 to 11 feet. The coals of the State are of two classes—caking or bituminous, and non-caking or block coal. The latter can be burned in blast furnaces without coking. The production in 1901 was 7,019,203 tons, valued at \$7,370,163, the State ranking sixth in the Union as to quantity and seventh as to value of the product. The number of people employed in coal mining was 12,968. The mineral product second in value was petroleum, the production of which is a

INDIANA

comparatively new industry. In 1901 the oil product of the State was 5,749,975 barrels, valued at \$4,795,312. This was largely increased—over one third—in 1902. Next in value of the mineral products of the State is building-stone, of which the chief varieties are the oolitic limestone, the blue Devonian limestone, the gray Niagara limestone, and sandstone. The oolitic, so called because composed of minute fossil shells resembling a mass of fish eggs, has become celebrated throughout the United States on account of its superior qualities. In 1901 Indiana was first in rank in the Union in the production of limestone for building purposes, and fifth in rank as to building-stone of all kinds, the product being valued at \$3,028,145. There is also a large production of cement and lime. Good clay is abundant throughout the State, and brick and tile making are extensive industries. Kaolin and glass sand are also found in quantity in several counties, and are profitably mined. Natural gas has been found, by sinking wells, throughout a large part of the State. The supply at one time reached a daily flow of 900,000,000 cubic feet. It served to draw many manufactories to the State, but the pressure is now decreasing. In many places its cessation has been followed by a flow of petroleum. Many other minerals have been found in Indiana, but not in quantities of commercial importance.

Manufactories.—The manufactures of Indiana are chiefly a development of the past 30 years. In the earlier period manufacturing was confined almost wholly to supplies for domestic consumption, and was chiefly conducted at the homes of the people. In 1900 there were reported 18,015 manufacturing establishments in the State, employing 155,956 wage-earners, and producing goods to the value of \$378,120,140. The leading classes of manufactures, with the value of products in 1900 and in 1890, are as follows:

	1900	1890
Slaughtering and meat packing	\$43,862,273	\$27,913,840
Flour and grist mills.....	30,150,766	31,239,627
Distilleries	22,738,106	9,677,973
Lumber and wood manufacturers	34,471,902	32,725,647
Iron and steel (including foundries).....	36,566,527	14,285,259
Glass and glassware.....	14,757,883	2,995,409
Carriages and wagons, and materials	15,801,826	10,531,683
Railroad cars.....	19,248,999	14,362,711
Agricultural implements.....	6,415,081	5,756,131
Textiles and clothing.....	8,618,360	7,736,890
Clay products.....	4,222,529	3,142,454

It is probable that this rate of increase will not be continued in the next decade, partly because of the decrease of natural gas, partly because of abandonment of plants under trust control, and partly for other reasons. The production of lumber in the State was almost stationary in the past decade, and will probably decrease in this on account of decreasing forest supplies.

Commerce and Navigation.—About one tenth of the people of Indiana (in occupations) are engaged in commerce and transportation. The navigation of the State is limited, being confined to the Ohio River on the south, with the

lower Wabash and a small part of the White River, and Lake Michigan on the northwest. The canals of the State are practically abandoned except for water-power. The railroads furnish the chief means of transportation. Commerce is chiefly domestic, but both exportation and importation are steadily increasing.

Fisheries.—Indiana has no fisheries of commercial importance, though it has waters that might be made valuable. Recently laws have been passed for the protection of fish, and some interest is being shown in their propagation.

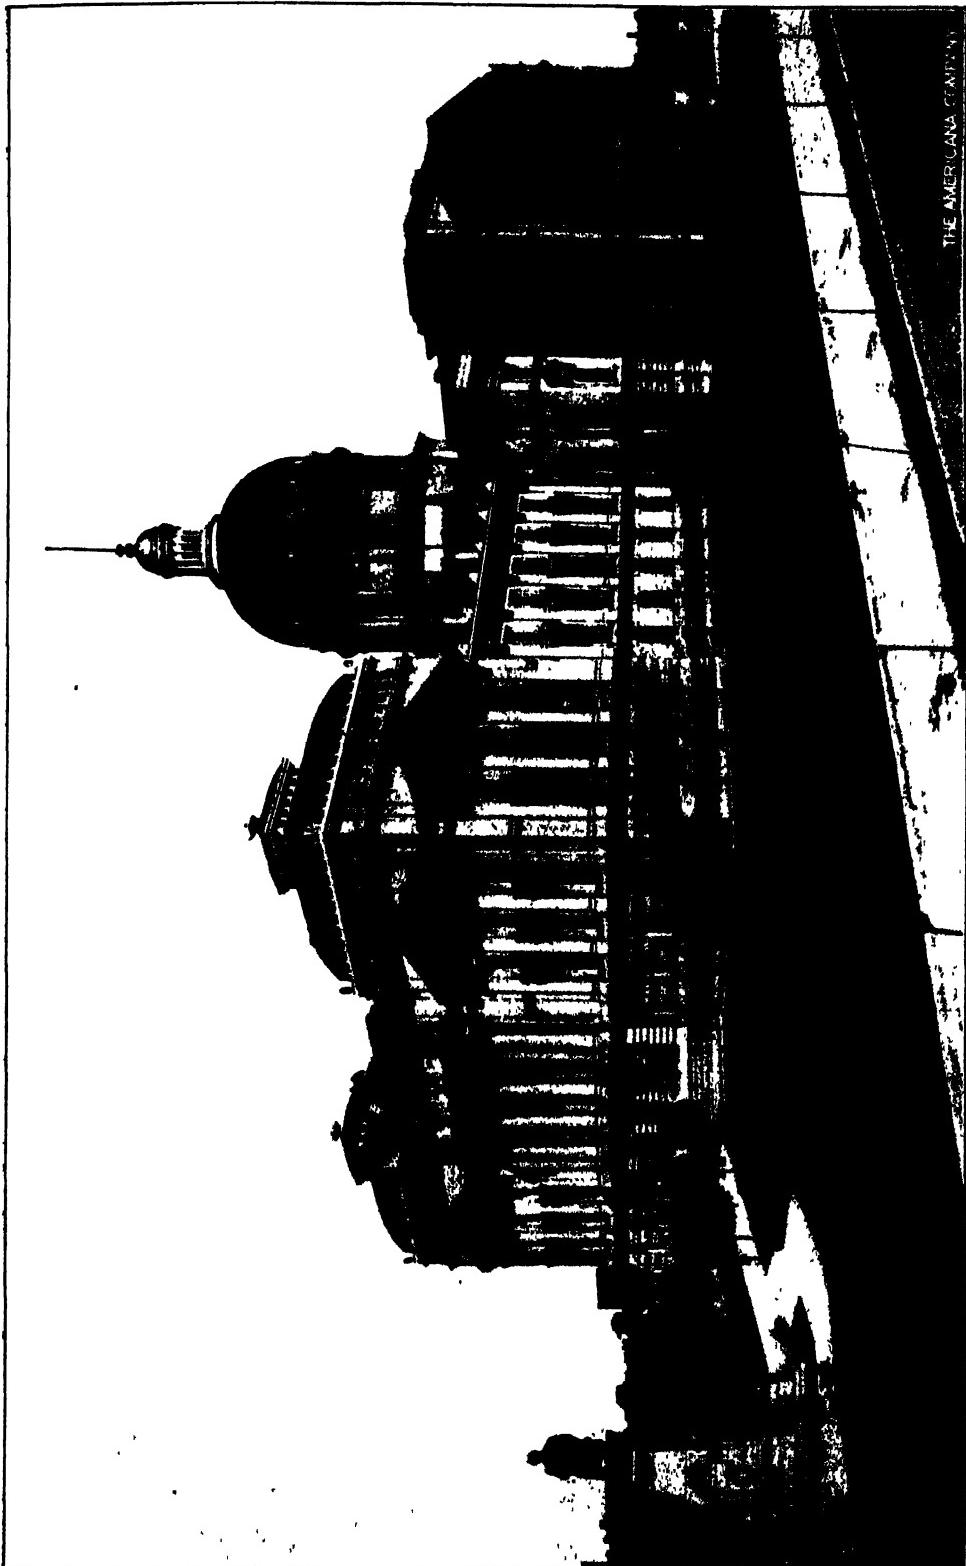

Railroads and Street Railways.—The railroad mileage of Indiana, in 1902, was 6,651 miles, exclusive of second main and side tracks. In 1850 it was 228 miles; in 1880, 4,320. Railroad lines extend through all but 3 counties in the State. The chief railroad centre is Indianapolis, from which 14 lines radiate. These are connected outside of the city by a belt railway. The valuation of railroad property for taxation in 1902 was \$162,797,978. There are street railways in all of the cities and larger towns, the total aggregating 168 miles. In 1899 there began an extraordinary development of electric interurban lines. By the close of 1902 about 400 miles of these were in operation, and 500 miles were under construction, while new lines aggregating over 1,000 miles were projected. These lines have made a material change in the transportation of both passengers and freight, and will apparently furnish large competition with the steam railroads. One of these lines, operating between Indianapolis and Columbus, Ohio, has added sleeping-cars to its equipment.

State Finances.—The assessed valuation of the State in 1901 was \$1,397,981,497, from which deductions for mortgage exemption were made amounting to \$35,160,250. Individuals are permitted to deduct *bona fide* mortgage indebtedness from their schedules to the amount of \$700. The total number of polls was 436,522. The State tax levy for general State government was 9 cents on \$100, and 50 cents poll; for the benevolent institutions 5 cents; for sinking fund 3 cents; for State tuition—which is distributed to the school districts for support of the common schools—11 cents and 50 cents poll; for State institutions of higher education 1½ cents; making a total State levy of 29½ cents and \$1 poll. The reduction of the State debt was begun in 1889, when it amounted to over \$10,000,000. On 31 Oct. 1902, it had been reduced to \$2,887,615.12, on which the annual interest charge was \$101,505.

Banks.—In 1902 there were 137 national banks with \$16,618,552 capital, \$4,789,956 surplus, \$71,533,942 deposits, and \$7,210,780 outstanding circulation; 113 State banks with \$4,884,490 capital, \$915,413 surplus, and \$24,240,334 deposits; 5 savings banks, with \$7,812,157 of deposits; 37 trust companies transacting bank business, with \$4,392,500 capital, \$465,947 surplus, and \$12,378,348 of deposits, and 203 private banks, which are not required to make returns by the State. Of these last named, however, 68 made returns to the comptroller of the currency, showing \$9,671,733 deposits. The only clearing-house organization in the State is at Indianapolis, and the volume of clearings in 1902 was \$270,409,456.

Education.—Indiana has always given much attention to education and especially since the

INDIANA.

THE AMERICANA COMPANY

STATE CAPITOL AT INDIANAPOLIS.

INDIANA

adoption of the present school law in 1852. At that time there was created a public school fund, the interest on which was to be distributed to the various school districts. The principal factor in this was the profits which the State had derived from the State Bank of Indiana, amounting to about \$3,500,000, to which was added \$573,000 of the surplus revenue distributed by Congress in 1836, and several smaller funds. To this additions have been made by fines and other public receipts, until in 1902 the common school fund amounted to \$7,978,580.68, to which is to be added the Congressional township fund, derived from the sale of school lands donated by the national government, amounting to \$2,465,304.64. This total fund of \$10,443,885.32 is held by the several counties, and the interest on it is applied to the support of the public schools. Added to this is a State tax of 11 cents on each \$100, and 50 cents on each poll, the proceeds of State liquor licenses and dog licenses, and local taxes assessed by local authorities. From all these sources the actual revenues raised for the public schools in 1902 amounted to \$8,585,354.98. The enumeration of children of school age—6 to 21 years—was 761,801 (of whom 15,002 were colored). A large number of these attended private schools, and the attendance in the public schools for the year was 423,078. The revenue was therefore in excess of \$20 to each child in attendance. There were employed 16,039 teachers, and the average number of days of school was, in townships 126, in towns 153, in cities 179, in the State at large 146. The number of public schoolhouses is 5,080 brick, 4,807 frame, 97 stone, and 3 log. The value of schoolhouses and grounds is \$22,904,607 and of school apparatus \$1,277,455. In these figures are included 704 high schools, which are a part of the public school system. There are also a large number of private schools, notably those maintained by the Roman Catholics and Lutherans for children of all ages, and a number of academies, seminaries, institutes, boarding-schools, military institutions, colleges, normal schools, etc., for intermediate education.

There are three institutions of higher education that receive aid from the State, Indiana University at Bloomington, the State Normal School at Terre Haute, and Purdue University at Lafayette. Indiana University has an income of about \$125,000 derived from a State tax levy and the interest on an endowment fund of \$600,000 raised by State taxation. It had 1,285 students in 1902. The State Normal is also supported by a State levy, and the city of Terre Haute pays one half the expense of keeping the buildings in repair. It has 1,406 students. Purdue has an income of \$150,000 derived from State tax levy and interest on endowments, and including \$57,000 paid to it annually by the United States government as an agricultural school. It has 1,180 students.

Among the private institutions for higher education the more important are Wabash College (Presbyterian), University of Notre Dame and St. Meinrad's College (Roman Catholic), DePauw University (Methodist), Earlham College (Society of Friends), Franklin College (Baptist), Hanover College (Presbyterian), Northern Indiana Normal (non-sectarian), Winona Technical Institute (non-sectarian), and the University of Indianapolis. The last

named was formed by the union of Butler College (Christian) with the Medical College of Indiana, the Indiana Dental College, and the Indiana Law School, all of which are located at Indianapolis.

An important branch of educational work in Indiana is the development of libraries. A feature of the school system adopted in 1852 was the establishment of a free public library in each township in the State. The State expended \$273,000 for books, and the system was received with great public favor, but no provision was made for maintaining or increasing the libraries, and in the pressure of the war times they were allowed very generally to fall into ruin. To some extent these have been replaced as school adjuncts by the libraries of the Young People's Reading Circle, which are found at many of the schoolhouses of the State. These libraries in 1902 contained 436,151 volumes. There has also been a notable development of town and city libraries, 28 towns having accepted donations from Andrew Carnegie, aggregating \$660,000, agreeing to maintain libraries in the buildings thus provided. There are 25 others that are maintaining libraries in buildings provided by themselves. The general supervision of library work is lodged in the Public Library Commission, which has charge of a system of traveling libraries furnished by the State. It also maintains a school for the training of librarians engaged in the work in Indiana.

Churches.—The principal religious denominations of Indiana in the order of their strength are the Methodists, Roman Catholics, Disciples or Christians, Baptists, Presbyterians, United Brethren, and Lutherans.

Charitable and Penal Institutions.—The State maintains 9 charitable and 4 penal institutions, at an annual cost of over \$1,500,000. Of the former, 4 are hospitals for the insane located respectively at Indianapolis, Logansport, Richmond and Evansville. On 31 Oct. 1902, these had 4,039 inmates. The annual cost of maintenance was \$649,834.54, or \$173.79 per capita. The other charitable institutions are the Institution for the Blind, Indianapolis, inmates 127, per capita cost \$276.40; Institution for the Deaf, Indianapolis, inmates 318, per capita cost \$231.66; Soldiers and Sailors' Orphans' Home, Knightstown, inmates 603, per capita cost \$174.52; Soldiers' Home, Lafayette, inmates 739, per capita cost \$167.30; School for Feeble-Minded, Fort Wayne, inmates 318, per capita cost \$127.05. The correctional institutions are the State Prison, Michigan City, inmates 796, per capita cost \$133.32, earnings \$53,395.86; Indiana Reformatory, Jeffersonville, inmates 923, per capita cost \$130.68, earnings \$62,350.67; Reform School for Boys, Plainfield, inmates 531, per capita cost \$122.13, earnings \$298.91; Industrial School for Girls and Women's Prison, Indianapolis, inmates 52 women and 175 girls, per capita cost \$191.55, earnings \$1,436.69. At the legislative session of 1903 a law was passed for the division of the last named institution and the establishment of a new Industrial School for Girls. The State has the convict-contract-labor system, but efforts have been made to abolish it, and the legislature of 1903 provided for a commission to investigate and report on the subject. The convict labor is all done within the prisons. The State has the indeterminate sentence system with commutation of time for

INDIANA

good behavior. In addition to the State institutions each county maintains a poor asylum. In these, and the Marion County asylum for the incurable insane, there were on 31 Aug. 1902, 3,046 inmates, of whom 1,975 were men and 1,071 women. Of these inmates 518 were classed as insane, and 889 as feeble-minded. There are in the State 46 orphans' homes, in which there were on 31 Oct. 1902, 1,565 inmates, of whom 1,025 were boys and 540 girls. At the same date the Board of State Charities reported 811 orphan children maintained in private homes, without public expense.

State Government.—The elective State offices are held for periods of 2 years, with eligibility restricted to 4 years in any period of 6 years, except as to the governor, lieutenant-governor, and geologist, whose terms are 4 years. No one is eligible to the office of governor or lieutenant-governor for more than 4 years in any period of 8 years. The governor's salary is \$5,000, with an allowance of \$1,800 for house rent. The governor's veto power extends to all laws passed by the legislature, but the veto may be overthrown by a majority vote in both Houses. The legislature meets once in 2 years, and may be called in special session by the governor; regular sessions are limited to 60 days and special sessions to 40 days. The Senate is composed of 50 members elected for 4 years each, and the House of 100 members elected for 2 years each. The members receive \$6 a day while in session, and \$5 for each 25 miles traveled in reaching the capital and returning home. The State is required to be redistricted for legislative purposes every 6 years. The present Constitution was adopted in 1851, and is very generally considered unsatisfactory, especially as to legislative representation and the location of the appointing power. It can be amended only by the majority vote of both Houses of two consecutive legislatures, followed by a majority vote of the electors of the State.

Congressional Representation.—The State has 13 representatives in Congress.

Population and Divisions.—The population of Indiana territory in 1800 was 5,641, but only about 2,500 of this was within the boundaries of the State. In 1810 the population of the territory, with practically the same boundaries as the State, was 24,520. A territorial census taken in 1815 showed 63,897 inhabitants. After the admission of the State the census returns were as follows: 1820, 147,178; 1830, 343,031; 1840, 685,866; 1850, 988,416; 1860, 1,350,428; 1870, 1,680,637; 1880, 1,978,301; 1890, 2,192,404; 1900, 2,516,402. Of the population in 1900, 142,121 were foreign born, and 57,505 were negroes. The tendency of the negroes is to gather in the cities, more than one fourth of the entire number being found at Indianapolis, and an eighth at Evansville.

The State has 92 counties, whose names and county-seats are as follows:

Adams, Decatur.
Allen, Ft. Wayne.
Bartholomew, Columbus.
Benton, Fowler.
Blackford, Hartford City.
Boone, Lebanon.
Brown, Nashville.
Carroll, Delphi.
Cass, Logansport.
Clark, Jeffersonville.
Clay, Brazil.
Clinton, Frankfort.

Crawford, English.
Daviess, Washington.
Dearborn, Lawrenceburg.
Decatur, Greensburg.
DeKalb, Auburn.
Delaware, Muncie.
Dubois, Jasper.
Elkhart, Goshen.
Fayette, Connersville.
Floyd, New Albany.
Fountain, Covington.
Franklin, Brookville.

Fulton, Rochester.	Orange, Paoli.
Gibson, Princeton.	Owen, Spencer.
Grant, Marion.	Parke, Rockville.
Greene, Bloomfield.	Perry, Cannelton.
Hamilton, Noblesville.	Pike, Petersburg.
Hancock, Greenfield.	Porter, Valparaiso.
Harrison, Corydon.	Posey, Mt. Vernon.
Hendricks, Danville.	Pulaski, Winamac.
Henry, Newcastle.	Putnam, Greencastle.
Howard, Kokomo.	Randolph, Winchester.
Huntington, Huntington.	Ripley, Versailles.
Jackson, Brownstown.	Rush, Rushville.
Jasper, Rensselaer.	Scott, Scottsburg.
Jay, Portland.	Shelby, Shelbyville.
Jefferson, Madison.	Spencer, Rockport.
Jennings, Vernon.	Starke, Knox.
Johnson, Franklin.	Steuben, Angola.
Knox, Vincennes.	St. Joseph, South Bend.
Kosciusko, Warsaw.	Sullivan, Sullivan.
Lagrange, Lagrange.	Switzerland, Vevay.
Lake, Crown Point.	Tipppecanoe, Lafayette.
Laporte, Laporte.	Tipton, Tipton.
Lawrence, Bedford.	Union, Liberty.
Madison, Anderson.	Vanderburg, Evansville.
Marion, Indianapolis.	Vermilion, Newport.
Marshall, Plymouth.	Vigo, Terre Haute.
Martin, Shoals.	Wabash, Wabash.
Miami, Peru.	Warren, Williamsport.
Monroe, Bloomington.	Warrick, Boonville.
Montgomery, Crawfordsville.	Washington, Salem.
Morgan, Martinsville.	Wayne, Richmond.
Newton, Kentland.	Wells, Bluffton.
Noble, Albion.	White, Monticello.
Ohio, Rising Sun.	Whitley, Columbia City.

Chief Cities.—The largest city in Indiana is the capital, Indianapolis, with a population (1900) 160,164. Next in size are Evansville (59,007), Ft. Wayne (45,115), Terre Haute (36,673), and South Bend (35,999). Each of these cities has a charter specially made for it, though under guise of a general law. These charters are of recent creation—the oldest made in 1891—and establish advanced forms of city government. Of cities of secondary importance may be named Muncie (20,942), New Albany (20,628), Anderson (20,178), Richmond (18,226), Lafayette (18,116), Marion (17,337), Logansport (16,204), and Elkhart (15,184). There were in all 80 cities and 330 incorporated towns in the State in 1901.

History.—The first-known visits of white men to Indiana were those of Sieur de la Salle, who followed the Ohio River along its southern boundary in 1669-70, and crossed its northwestern corner by way of the St. Josephs-Kankakee portage in 1671. There were no Indians living below the Wabash at that time, and probably not many in the northern part of the State, but those there were LaSalle induced to join his confederacy against the Iroquois, and they all removed to the Illinois River, leaving Indiana practically uninhabited. After some years they began moving to the East, reaching Detroit by 1712, and shortly afterward located at points along the Maumee and Wabash rivers. The Delawares, who afterward lived in the central part of the State, on White River, came there about 1750. It is probable that the French first placed representatives at the Indian villages near the site of Ft. Wayne, and next, about 1720, at Ouiatenon—on the north side of the Wabash just below Lafayette—and that there were stockade forts at these places, but there is nothing to indicate a permanent settlement at either place. The post at Vincennes was established in 1731, largely under the influence of Father De Beaubois, a Jesuit who had been stationed at Kaskaskia. Families located there soon afterward, and it remained a permanent settlement, though there is but one land grant recorded of

INDIANA

date prior to 1736. The French posts were small and unimportant, and the history of the region under French and British rule presents no very striking features. In 1778 Vincennes was surrendered to representatives of Gen. George Rogers Clark, and the Wabash country was brought under American control. A recapture by the British was followed by a second taking by Clark in 1779. The region was ceded to the United States by the treaty of 1783, and was included in the Territory northwest of the Ohio River, by the ordinance of 1787. It was thus governed until 1800, when Indiana Territory was formed, including all of the Northwest Territory except Ohio. From Indiana Territory, Michigan Territory was cut off in 1805, and Illinois Territory in 1809, leaving it with practically the present State boundaries. By act of Congress of 19 April 1816, Indiana was authorized to form a State government, and the State was formally admitted by act of 11 Dec. 1816. In the meantime a State Constitution had been adopted on 29 June; State officials had been elected, and the State government had been actually inaugurated on 7 November.

There were almost continuous Indian troubles in the Ohio Valley from 1788 to 1795, when, after Gen. Wayne's successful expedition, peace was made at Ft. Greenville. After that date the American immigration began, and there was no material trouble with Indians until the formation of Tecumseh's confederacy in 1811. The Indians were overwhelmed at the battle of Tippecanoe (q.v.) on 7 November of that year, by the troops under Gen. Harrison, and sued for peace, but when the war with England came on there were Indian hostilities of minor importance continuing until the close of the war in 1815. After that year there was a gradual extinction of Indian titles, the Indians being concentrated in the northern part of the State and finally removed west of the Mississippi. The last removals occurred in 1836 and 1838.

The sobriquet "Hoosier," commonly used to designate the State and its people, was first applied to them about 1830. It was not coined for that purpose, as is commonly supposed, but was a slang word signifying an uncouth rustic, which was in common use in the South at that time, and is still commonly used there in that sense.

The history of the State after its admission was chiefly that of peaceful development—clearing lands, opening roads, building towns and cities, and establishing industries. The most notable feature was the disastrous internal improvement enterprise on which the State entered in 1836. It contemplated transportation routes on 7 main lines, involving the construction of 1,289 miles of railroads and canals. That the routes were fairly well chosen is shown by the fact that they are now practically all occupied by successful railroad lines. The chief defect was that the improvements were mostly high-line canals, and the breaks in these before completion caused such great damage that the estimated cost was enormously increased. The financial panic of 1837 added to the difficulties, and the effects of this were aggravated by the general entering of the States on such enterprises on borrowed capital. The total debts of the several States swelled from about \$13,000,000 in 1830 to \$207,894,613 in 1842. In 1839 Indiana was unable to realize on the sales of her bonds, and was forced to default interest

on those already issued. The canals and roads being unfinished, did not furnish the revenues anticipated. Compromises were effected by which the work done was turned over to creditors, but the State was left with a debt of about \$10,000,000 without any property to represent it. In all, Indiana built 453 miles of canals, at a cost of \$7,725,262, all of which are now abandoned so far as transportation is concerned. But under private management, and more favorable conditions, the transportation lines developed rapidly, and in 1849 the one railroad originally contemplated was paying 8½ per cent dividends on its stock. In 1860 there were 2,126 miles of railroads in successful operation in the State.

In the war with Mexico, Indiana furnished troops to the number of 4,470. Of these there were killed and wounded 183, and died of other causes 218. When the Civil War began the State occupied an important position, and its resources were utilized to the uttermost by its war governor, Oliver P. Morton. The State furnished 106,363 men for the War, and 784 paid for exemption, or in other words supplied 74.3 per cent of her total population capable of bearing arms, by the census of 1860. Only one State in the Union surpassed or equaled this record, Delaware being credited with 74.8 per cent of her military population. But of the supply credited to Delaware nearly one tenth was in money commutation for exemption, and nearly one tenth of the men in actual service were colored. On the basis of white troops furnished for 3 years or more of service, Indiana supplied 57 per cent of her military population of 1860, and on this basis was surpassed only by Kansas, which is credited with 59.4 per cent. Of the troops sent by Indiana 7,243 were killed or mortally wounded in battle, and 19,429 died of other causes, making a total death loss of over 13 per cent of all troops furnished. One feature of the War period in Indiana, and some adjoining States, was the formation of secret treasonable societies known as Knights of the Golden Circle, and later Sons of Liberty. These attracted much attention at the time, and much comment later, but in reality they were neither extensive nor dangerous. They were organized with a system of "circles within circles," with mysterious rites and blood-curdling oaths, but the masses of the members understood that they were merely for mutual protection, and the treasonable designs were affairs of the inner circles. Among their members there were a number of government detectives who kept the authorities informed as to every movement, and at the final exposure the chief witness for the government was Felix Stidgers, a detective who had become so prominent in the order that he was made "Grand Secretary for Kentucky," and knew all of the secrets of the order. As is aptly stated by Gov. Morton's biographer, "No one can read the history of the secret organizations in Indiana and not feel that, widespread as they were, there was not an instant in which they were not securely within the grasp of the war governor." After the War, Indiana became peculiarly a political battleground. In 1868 the Republicans elected Conrad Baker governor by less than 1,000 plurality, and in 1872 the Democrats elected Thomas A. Hendricks to that office by the narrow plurality of 1,148, although Gen. Grant received the vote of the State for President. After 1872 neither

INDIANA UNIVERSITY—INDIANAPOLIS

party carried the State at two consecutive Presidential elections until after 1896, and neither carried it by a majority of all the votes cast, or by a plurality of as much as 20,000. One result of this close balance has been an improvement in State legislation, the Democrats leading in the legislature of 1889 which they held although they had lost the State offices and the Presidential vote of the State in the preceding year. Indiana in that year adopted the Australian ballot system, being the second State in the Union to do so, with some improvements that have been extensively copied. Other notable reform laws are a school-book law that has made a large reduction in the cost of books used in the common schools; a Board of State Charities law that has greatly improved the charitable and penal institutions of the State; a fee and salary law putting officials on salaries and requiring the payment of all fees into the public treasuries; a compulsory education law; laws for the encouragement of public libraries; laws for the incorporation of cities which provide the most modern modes of city government; laws for the reform of county and township government providing supervisory boards to which local legislation is entrusted and a tax law that has been largely effective in equalizing taxation and has been copied elsewhere. Another feature of Indiana's development that has attracted notice in later years is its production of native writers of poetry and fiction. Among the former may be named Joaquin Miller, John Hay, John James Piatt and James Whitcomb Riley; among the latter Gen. Lew Wallace, Maurice Thompson, Edward Eggleston, Charles Major, Meredith Nicholson, Booth Tarkington and Annie Fellows Johnston. These with lesser lights and some writers of note in other lines form a notable group for a commonwealth whose settlement and development have occurred in little more than a century.

JACOB PIATT DUNN,
Secretary Indiana Historical Society.

Indiana University, the State university located near Bloomington. In accordance with a provision of the State constitution, the legislature passed an act in 1820 providing for the establishment of a State seminary, which was opened in 1824 under the name of Indiana Seminary; in 1827, it was raised to the dignity of a college, and in 1838 the name was changed to Indiana University. In 1869 the university was opened to women, and has since been coeducational in all its departments. The university is the head of the public school system of Indiana, and no tuition fee is charged; the government is by a board of trustees which reports biennially to the governor. Courses are offered in languages, science, and history, all graduates receiving the degree of A.B. The degrees of Ph.D. and A.M. are given for graduate work; there is also a school of law connected with the university which confers the degree of B.L. There is a biological experiment station on Winona Lake, under university control, and a summer session is maintained. In 1902 the annual income amounted to \$140,000; the number of students was 1,285.

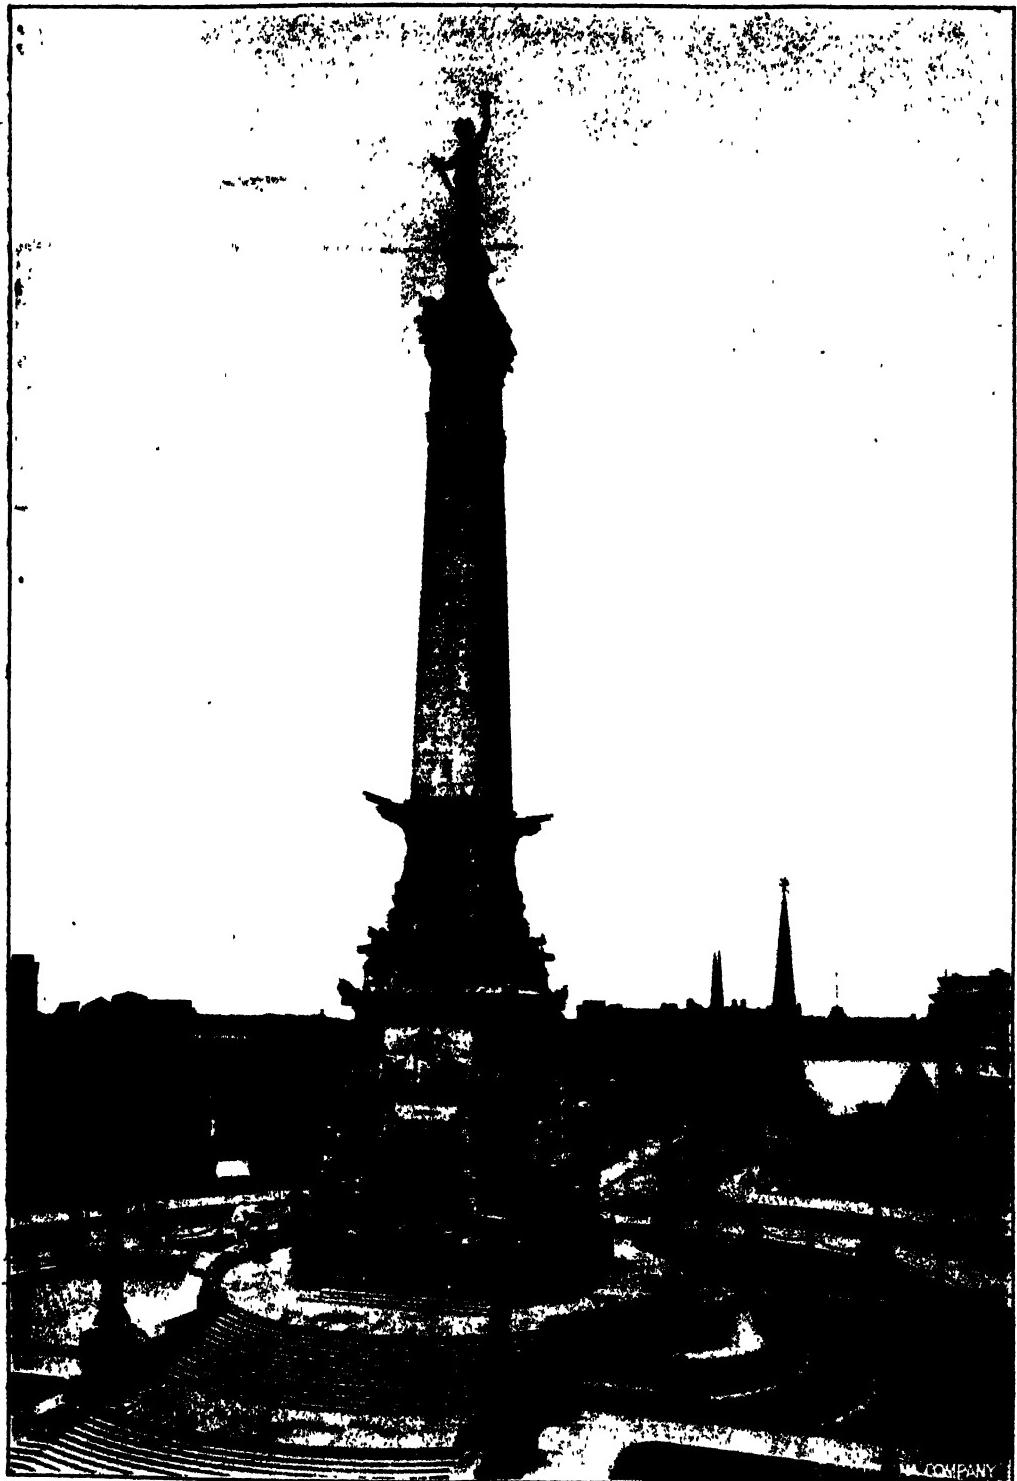

Indianapolis, Ind., capital of the State, county-seat of Marion County, the largest city in the State and the 21st in the United States; situated on the west fork of White River. It is

the centre for 16 radiating railroads, which connect it with Chicago, 184 miles northwest, Cleveland, 283 miles northeast, St. Louis, 240 miles southwest, Louisville, 110 miles south, Cincinnati, 111 miles southeast, Columbus, 181 miles east, New York, 819 miles east, and other termini in Ohio, Michigan, Illinois, and Indiana. Its area is 29.35 square miles.

The site was selected in 1820 as the location of the capital by a legislative commission, and its name was adopted by the legislature in session at Corydon, 6 Jan. 1821. The first plat included a square mile, which was laid out with broad rectangular streets and avenues radiating from a central circle. The character of the plan was undoubtedly influenced by l'Enfant, the designer of the city of Washington, D. C., for one of the surveyors who made the town plat had aided in the work at the national capital. While the additions to the city have not been developed upon the same broad lines, most of them have been treated liberally and the city is noted for its wide streets, well paved and beautifully shaded. The city is very level, nearly all of its area being 700 to 800 feet above sea-level. There are 439.6 miles of platted streets, of which 92 miles are paved, 44 miles with asphalt, 27 miles with brick, 17 miles with wooden blocks, and 4 miles with macadam. The chief business streets are Washington Street, which is a section of the old National road projected and partly completed to run from Baltimore to St. Louis; Market, Maryland, and Georgia streets, all running east and west; Meridian, Pennsylvania, Delaware, and Illinois streets, running north and south, and Massachusetts, Indiana, Virginia, and Kentucky avenues, which are diagonals, radiating from the circular Monument Place. This central circle contains the State's monument to its soldiers and sailors, perhaps the most successful of the innumerable monuments erected by towns, cities, societies, and States in commemoration of the nation's defenders, and is generally regarded as one of the greatest in the world from an artistic point of view. The finest residence streets are Delaware, Meridian, and Pennsylvania. Several other residence districts are particularly well designed and cared for, such as Woodruff Place—a residence park, with esplanades, fountains, statues, etc.—which has a town government of its own, though completely surrounded by the city; Morton Place, and Meridian Heights.

Public Service.—The first water supply and the first sewer system were constructed in 1870 to 1875, and but little else was done in the way of comprehensive public improvements until after the adoption of the present efficient charter in 1891. Prior to that year the city government had been by mayor and council. Public-spirited citizens who recognized the impossibility of comprehensive public improvements, through the Commercial Club and Board of Trade agitated the adoption of the new charter, which separated the legislative and administrative functions of the city government, making the mayor and his appointees fully responsible for the latter. The first Board of Public Works devised a broad system of improvement, including sewerage, paving and street cleaning, which was supplemented in 1895 by a Park Commission. Under these two boards the progress in the establishment of municipal public works adding to the beauty and convenience of the city has been rapid. As a step preliminary to the era of im-

INDIANAPOLIS.

SOLDIERS' MONUMENT.

INDIANAPOLIS

provement which began in 1890 a paving exposition was held for the purpose of educating the people of the city regarding paving materials and methods. It was the first ever held in America and attracted attention throughout the country. Official delegations were sent to it from many cities. Prior to 1890 less than two miles of pavements had been laid. The amounts expended since the adoption of the new charter in 1891, including the year 1902, are as follows: for pavements of asphalt, \$2,726,668.01; brick, \$1,011,214.39; wooden block, \$969,652.82; macadam, \$154,522.91; gravel, \$757,112.50; for alley improvements, \$46,655.26; for cement walks, \$879,610.21; for brick walks, \$65,995.41; making a total for paving of \$6,611,431.51. During the same period the expenditure for construction of 105 miles of sewers added to the 23 miles previously in use was \$1,828,878.67, and for bridges \$240,485.32. The grand total for the 12 years shows \$8,680,795.50 expended in these departments of public improvements. The waterworks owned by the Indianapolis Water Company have developed with the city. The system of pumping by direct pressure is used, and a system of filter beds to purify the water taken from White River some miles above the city has been installed. The company has 226 miles of water mains and receives from the city about \$85,000 a year for public water and fire protection service. Electric lights are in general use. The city pays about \$115,000 a year for about 1,350 electric arcs for street lighting and about \$7,000 for about 400 gas and vapor lights. The police department contains 175 men and costs \$150,000 a year. The police court, city clerk, city dispensary, and central station are housed in a handsome building of recent construction. The fire department has 100 horses, 9 steam fire-engines, 20 hose wagons, 1 water tower, 1 aerial, and 4 service trucks, 4 chemical engines, and 175 men, and is housed in 22 stations. It costs the city \$175,000 a year. There are 50 miles of underground conduits used by the telephone, telegraph and electric light and power companies, and 125 miles of electric street railway lines, owned by the Indianapolis Street Railway Company. The city is the most prominent centre of interurban railway traffic in the United States. Ten systems are in operation or in active construction, and others are early probabilities. The city has recently made a contract with the Indianapolis Terminal and Traction Company, lessee of the city lines, under which a great terminal station and belt lines for the passenger and freight traffic of the interurban lines are under construction, the whole making a model system.

Parks and Cemeteries.—The public park system includes 9 parks of nearly 1,200 acres area. Riverside Park, purchased in 1898, contains 950 acres along White River, Garfield Park 108 acres, and Brookside Park 80 acres. Since the establishment of the park commission in 1895 \$300,000 has been spent in purchasing new parks and \$400,000 in improving them. There are several small parks scattered about the city, such as Military Park, 14 acres; University and St. Clair Squares, each 4 acres; Spades Place, 8 acres; Indianola Place, 2 acres; Highland Square, and combinations of park, boulevard, and residences as Elmwood, Fletcher, Morton, and other places, of which the largest is Woodruff Place, above noted. The city street railway company maintains two parks a short distance

outside the city limits. The first cemetery of the city, Greenlawn, has not been used as such for many years and is kept in park form by the Board of Park Commissioners. Crown Hill cemetery, one of the notable cemeteries of the country, embraces over 540 acres. There are also Roman Catholic, Lutheran, and Jewish cemeteries.

Buildings.—The Indiana State House, costing \$2,000,000, and built of Indiana colitic stone, is perhaps the most notable building. With its grounds it occupies two large blocks. The county building was completed in 1878 at a cost approximating \$1,750,000. The new Federal building, containing the post-office, custom-house, and United States courts, is under construction at a cost of \$2,400,000. Other municipal buildings of note are the police building, the public library, containing also the offices of the public schools, and some of the new public school buildings. Tomlinson Hall, a bequest by Dr. J. M. Tomlinson, is a public building, its lower story being used as a market. The Indianapolis Art Association is considering plans for an art museum and school. Among the prominent business buildings ornamenting the city, special mention may be made in the order of their construction of the Commercial Club, Majestic, Law, Stevenson and Newton Claypool buildings and Claypool Hotel. The Columbia Club building is an important feature of one quadrant of Monument Place, which surrounds the Indiana State Soldiers and Sailors' monument. This massive shaft is the central and most notable decorative feature of the city. It is 285 feet high, including the bronze statue, and its base is ornamented with symbolic groups of statuary and reliefs in stone and bronze. It was designed by Bruno Schmitz and cost over \$500,000. Four epochs in the history of the State are commemorated by the statues of George Rogers Clark, William Henry Harrison, James Whitcomb, and Oliver P. Morton, which are grouped about its base. The width of Washington street, 120 feet, and of the streets of the original plat, 80 and 90 feet, give space for the best possible display of architectural features.

Transportation.—Indianapolis is the centre of trade for the State. With the completion of the Indianapolis Southern Railway every county in the State except three, which are on the Ohio River, can be reached by railroad in less than one day's travel. Consolidations have placed most of the railroads in two systems. One of these, the Pennsylvania lines west of Pittsburgh, now operates the Madison and Jeffersonville lines, which reached the city in 1847, and the Vincennes line, completed in 1868; the Indiana Central to Columbus and the East, completed in 1853, and the Terre Haute and Richmond, later the Vandalia, completed in 1852, and now reaching St. Louis; also a line to Chicago, partly over the Lake Erie and Western. The other, the Big Four system, operates the Bellefontaine road to Cleveland, completed in 1852; the Indianapolis and Cincinnati, which reached the city in 1850; the Indianapolis and Lafayette, of 1852, now reaching Chicago; the Indianapolis, Bloomington and Western to Peoria, finished in 1870, its eastern extension to Springfield, O., completed about 15 years later; the Indianapolis and St. Louis, completed in 1876. Through trains are also run to Benton Harbor, Mich., and to Louisville, over branches of these lines. The

INDIANAPOLIS

Cincinnati, Hamilton and Dayton Railroad Company operates the Cincinnati and Indianapolis Junction road, completed in 1868, and the Indianapolis, Decatur and Springfield road to Springfield, Ill. The Indianapolis, Cincinnati and Louisville operates a line to Chicago, which was completed about 1880. The Lake Erie and Western Railroad Company operates the old Peru and Indianapolis road, completed in 1854, and reaches Michigan City, Toledo and Peoria.

The construction of the system of interurban electric roads began about 1890 with the Broad Ripple line, now a suburban city line. The next to be constructed was the Indianapolis and Greenwood line in 1900, now reaching Columbus, Ind. It was quickly followed by the Indianapolis and Eastern, which now connects with lines to Columbus, Ohio, and other Eastern points. The Union Traction Company entered the city with a line from its centre in Anderson in 1901 and completed a new line north to Tipton and other points in 1903. The Indianapolis, Shelbyville and Southeastern is another line completed in 1901. Lines entering the city in 1903 are the Indianapolis and Martinsville, the Indianapolis and Plainfield, and the Indianapolis and Northwestern, reaching Crawfordsville and Lafayette. The Indianapolis and Cincinnati is under construction in 1903 to Rushville, and contracts have been let for the Indianapolis and Southern railroad. The steam railroads are served within the city by the Union Railway Company owning the Union passenger station and the belt railway for facilitating the transfer of freight. The interurban electric roads will in like manner be served by the Indianapolis Terminal and Traction Company owning a large terminal station and belt lines for passenger and freight business.

Manufactures.—During the brief natural gas era in Indiana, Indianapolis benefited largely by the cheap fuel. Since the failure of the gas supply the superior shipping facilities of the city and relatively cheap coal fuel have attracted many more manufactoryes, and more than 160 industries are carried on in about 2,000 establishments. According to the United States census of 1900 there was invested in 1910 establishments capital amounting to \$36,828,114, employing 27,478 persons, including proprietors, and turning out products valued at \$68,607,579. Among the most important industries are slaughtering and meat packing, whose product was \$18,781,442 in the census year from 7 establishments; iron work of all sorts, \$6,727,990; flouring and grist mill products, \$3,820,373; carriages and wagons and material therefor, \$2,812,498; furniture factory product, \$1,685,827; saws, \$1,587,827; malt liquors, \$1,770,939; printing and publishing books and newspapers, \$2,924,385; clothing, \$2,190,050, half of it factory product; lumber and lumber-mill products, \$1,588,797.

Finances and Banking.—The assessed valuation of the city in 1870 was \$24,656,460. In 1891 at the beginning of the era of public improvements it was \$93,595,930, and in 1902 it had increased to \$132,927,210. The tax rate for State, county, township, city, and school purposes was \$2.08 in 1902. The bonded debt is \$2,421,000. The city's expenses are about \$1,200,000 a year. The post-office receipts are \$635,000. The custom-house receipts are \$165,000, and the valuation of imports \$350,000. There are 14 banks and trust companies, including seven national

banks. The aggregate capital of the national banks is about \$4,300,000, their surplus about \$1,900,000, and deposits over \$18,000,000. The six trust companies have a capital of \$2,900,000 and individual deposits of about \$7,500,000. The trust companies and private banks carry savings accounts. There are about 90 building, loan and savings associations in various stages of progress and liquidation.

Churches.—Indianapolis is the seat of a Roman Catholic bishop, with an auxiliary bishop and of an Episcopal bishop. Including missions there are 12 Roman Catholic churches in the city, 47 Methodist, 16 Presbyterian, 7 Episcopal, 34 Baptist, 10 Congregational, 7 Lutheran, 15 Christian, 3 German Evangelical, 3 Evangelical Association, 3 Friends, 2 United Presbyterian, 5 German Reformed, one each of 11 other denominations. There are 4 Hebrew congregations.

Charities.—In the city there are 15 hospitals, State, county, college, church, charitable, and private, 4 homes for the aged, 6 industrial schools and orphan asylums, 4 homes for women and girls, 16 organized charitable and relief societies, and several such institutions as the Y. M. C. A., Y. W. C. A., Friendly Inn, Bureau of Justice, Humane Society, Day Nursery. The township trustee is a source of official relief. The charities of the city are most efficiently administered, as a result of co-operation between organizations largely brought about through the efforts of Rev. Oscar C. McCullouch. In 1894 a plan of relief for the unemployed, whereby over 5,000 people were provided with the necessities of life throughout winter without pauperizing influences resulting, became widely known as the "Indianapolis Plan of Relief." It gave opportunity to worthy poor to earn credit at a market for food, fuel and clothing. The plan was devised and carried out on behalf of the people of the city by a Commercial Club committee composed of Hugh H. Hanna, Col. Eli Lilly, and William Fortune.

Education.—There are 60 public school buildings, including 2 high schools, one giving manual training, in which about 700 teachers are employed, with a total enrollment of about 35,000 pupils; 22 Catholic schools, 2 Lutheran schools, 5 private schools and academies, besides the schools in connection with institutions. The University of Indianapolis is an organization formed in 1896 to unite several institutions of the city, including Butler College, first incorporated in 1850 as the Department of Liberal Arts; the Medical College of Indiana, organized in 1869; the Indiana Dental College, organized in 1878, and the Indiana Law School. There are in all five medical schools, two dental colleges, a law school, and 21 business, music and other special schools. The United States Arsenal grounds in the city were purchased in 1902 for a technical institute. Free kindergartens are operated under the Free Kindergarten Association, and 23 kindergartens and a normal school are maintained largely from public funds, besides a number of private kindergartens. The Art Association of Indianapolis maintains the John Herron Art Institute, including art gallery, school, and museum. The Propylaeum is a building erected by an association composed exclusively of women.

Libraries.—The most notable libraries are the public library with about 100,000 volumes, under

INDIANOLA — INDIANS

the control of the board of school commissioners, and the State library with about 35,000 volumes. The State law library with 40,000 volumes, and agricultural and horticultural libraries in the State House, and the county library and bar association's library in the court-house may be noted. There are seven branches of the public library, including the newly erected Bona Thompson library of Butler College and many small special libraries of schools and associations.

Newspapers and Literature.—In 1903 the city had 9 daily papers, 23 weeklies, 38 monthlies, and 5 with other periods of issue. The list of trade and class papers published in the city is particularly notable. Indianapolis is the home of many writers whose names are familiar to the public, and it has in recent years become an important western book-publishing centre.

Organizations.—The development of the city has been markedly influenced by organized work in various directions. There are a great number of literary, art, and musical societies, and largely as a result of this activity there is a high standard of cultivation in such matters. This has had a notable influence in establishing in the social life of the city a standard of merit rather than determining the standing of the individual on questions of lineage or wealth. There are many social clubs, among the most notable being the University, Country, Contemporary, and Woodruff Clubs, the Deutsche Haus, the Männerchor, and the Elks, while the Columbia, Marion, and Indiana Clubs are political organizations, established in comfortable homes. The Columbia Club building, located on the Circle, is one of the finest club-houses in the United States. The Commercial Club, with a membership of over 1,000, which owns as its home an eight-story office building, was a dominant force in the new era of progress and development which started in 1890, and devotes itself to the welfare of the city. The Board of Trade, an older organization with a membership of about 500, has also been active in this direction. Organizations of various kinds, commercial, trade, fraternal, social, literary, art, musical, and miscellaneous, number over 500.

Government.—The administrative department is in the hands of a mayor, elected biennially, and of boards appointed by him. The council consists of 15 members elected one from each ward, and 6 members elected at large, with a two-years' term of office. The city clerk and police judge are also elected biennially. The mayor's appointees are the city comptroller, attorney, civil engineer, boards of public works, 3 members of public health and charities, 3 members of public safety, and of commissioners of public parks 4 members. The school system is in charge of a board of 5 school commissioners elected at special elections held for that purpose only.

Population.—Beginning with two or three families in 1819 or 1820, Indianapolis has shown a steady and rapid growth, having a population of 1,085 in 1830; 2,668 in 1840; 8,091 in 1850; 18,611 in 1860; 48,244 in 1870; 75,056 in 1880; 105,436 in 1890; and 169,164 in 1900. Since the last census the increase in population has been still more rapid. The growth of the city has been almost exactly parallel with that of Buffalo, but 20 years behind, and the parallelism promises to continue. In 1890 Indianapolis was 26th

in population, and in 1900 it was 21st in the United States.

History.—The first settler, George Pogue, arrived in March of 1819 or 1820. The legislature of Indiana, meeting at Corydon, by committee selected, in 1820, the site for a State capital, and named it Indianapolis, 6 Jan. 1821. Another committee laid out the plat. Lots were slowly sold for several years, and the government was actually removed to the new capital in 1824, the first session of the legislature being held there in 1825. The first State House, modeled after the Parthenon, was completed in 1835. A town government was instituted in 1832 under three trustees, a town council was established in 1838, and a city government under mayor and council in 1847. The present metropolitan form of government, with the mayor as the responsible administrative officer and the council as the legislative branch, was adopted in 1891. A volunteer fire department was formed in 1826, which had much help from the State when the capitol building was completed. The first fire chief was appointed in 1853, and the department was changed to a corps of paid men in 1859. The police department was first established in 1854. The new town began to support a newspaper in January 1822, and a church in 1823. The first railroad reached the city in 1847, and several others were completed in the next four years. Their effect upon the town is seen in the large increase in population. The State capital was the centre of great activity during the War, and there was great expansion in business and manufactures as well as increase in population, most of which was retained. The city did its full share in raising regiments for the War, and is said to have expended a million dollars in contributions, bounties, and war expenses. Camp Morton, on its outskirts, was first a camp for training soldiers, and later for prisoners of war. The free school system now cited as a model by educational experts, was begun in 1853 with the accumulations of several years of special taxation spent in buildings and grounds. The Citizens' Street Railway charter was granted 18 Jan. 1864. The slaughtering and packing business, now so large a factor in the city's trade, began its great expansion in the same year. Public improvements were but few in number until the adoption of the new charter in 1891.

Indianapolis has numbered among her prominent citizens Benjamin Harrison, Thomas A. Hendricks, and others high in the affairs of the national government. *WILLIAM FORTUNE, Prest. Municipal Engineering Co., Indianapolis.*

Indianola, Iowa, city and county-seat of Warren County, 18 miles south of Des Moines, on the Chicago, B. & Q. and the Chicago R. I. & P. R.R.'s. There is a large and increasing trade here in grain, butter, eggs, fruit, live stock and garden products. Here is the seat of the Simpson Methodist Episcopal College, founded in 1867. The electric light plant is owned by the city. Pop. (1890) 2,254; (1900) 3,261.

Indians, American. Columbus, when he discovered America, believed he had reached a part of Asia, or of India, and in a letter of February 1493 wrote of "the Indians (in Spanish, *Indios*) I have with me." Thus the aborigines of the New World came to be called "Indians" (French *Indiens*, German *Indianer*,

INDIANS

etc.), or, to avoid confusion with the natives of India, "American Indians," for which rather cumbrous term the word "Amerinds," susceptible of many modifications by means of prefix and suffix, and easily adaptable to the exigencies of modern European and other civilized languages, has been suggested by an eminent American lexicographer and is used more or less by a number of anthropologists and other writers. The word "American," originally applied to the Indians, is still somewhat in use, and Dr. D. G. Brinton styled his comprehensive sketch published in 1891, "The American Race"; but its employment to designate the white population of the continent seems to bar its ethnological application to the aborigines without some qualifying term. By some writers the Indians are called the "Red Race," and, more popularly, "Redskins" (in French *Peaux-Rouges*, in German *Rothäuse*), or "Redmen," terms of no exact somatic significance. A few American, and many European, ethnologists continue to separate the peoples who created the civilizations of Mexico, Central America, Peru, etc., from the Indians, while others exclude the Eskimo, and others, again, the "Mound-Builders." But somatic, cultural, and linguistic evidence justifies the conclusions of Powell and Brinton in using the term "American Indians" to include not only the aborigines now existing, or known to have existed since the discovery, but also all the pre-Columbian peoples of America concerning whom we have little data,—the most divergent are no more than sub-varieties of American man. This unity is the great ethnic phenomenon of American aboriginal history. The study of Indian languages, archaeological remains, arts, and industries, games, social and religious institutions, mythology and folk-lore indicates a general psychic unity, while the somatic diversities do not transcend those observable in the other great races of mankind. Whether one investigates, as McGee has so admirably done, the Seri of the Gulf of California, who represent about the lowest type of savage culture on the North American continent, or the Mayas of Yucatan, whose approach to a phonetic system of writing touches the high-water mark of Amerindian achievement, one receives the same impression: that it is a question not of very recent civilized or semi-barbaric intruders from Asia or from Europe, but of a race (whatever their remoter origins may be) who have dwelt for ages in an American environment, which has shaped them into the peoples met with by the whites at the time of the Columbian discovery. The limited effect of the "discovery" of the Norsemen may be held to discount any "discoveries" by Europeans before them; while, on the other hand, the American-Asiatic contact revealed by the investigations of the Jesup North Pacific expedition is as much American as Asiatic, and the "Bering Sea" culture is a local phenomenon no more fundamentally indigenous to the Old World than to the New. The arguments in favor of a trans-Pacific Malayo-Polynesian influence upon primitive America are no stronger than those that can be adduced to support the contrary opinion. The culture of the "Mound-Builders" does not in any way transcend the possibilities of what the American Indian was and is yet capable of, nor is it necessary to assume the presence of foreign culture-elements

to explain the civilizations of Mexico, Yucatan, Colombia, and Peru. Since very primitive times America has been essentially the "ethnic island" of Brinton, Keane, and other investigators. The impress of America has been upon the aborigines so long that physically, socially, linguistically they have been "Americanized" in so marked a fashion that their right to be considered one of the "races" of mankind is not to be dismissed without cause. To group them merely as a branch of the Mongolian, or, again, of the Malay "race," is to obscure many points of great importance in the prehistory of America or to ignore them altogether. The American Indian is in too many respects a modified (and anciently so) variety of mankind to be thought of as expressing in any serious degree the type of the Mongolian or the Malay.

Language and Culture.—The ethnic isolation of the American race has already been noticed. The apparent independence of the culture-centres of North and South America is another interesting fact. With the exception of a few possible traces of the presence of tribes of Arawak lineage in ancient Florida and the spread of art-motifs of the Caribbean type over a portion of the adjacent Gulf region, no direct evidence of the influence of South America upon North American culture is forthcoming. The independent origin of Mexican and Peruvian civilizations seems certain, and convincing proofs of the community of origin of Peruvian and Chibchan and even of Mexican and Mayan are lacking. The possibility of inter-cultural relations having once existed is, however, not to be denied. The Pacific coast, from the Gulf of California to the Argentine and Chile, has been a nursery of culture just as the Mediterranean area was for the Eurafican peoples. There has been a Mexico and a "greater Mexico," a Peru and a "greater Peru," while the Mayas and the Chibchas have also had their extensive spheres of influence. To the Pueblo culture north of Mexico corresponds the Calchaqui culture south of Peru. On the northern borders of Mexico still lie the savage Seri and Yaqui, and the culture-areas of Colombia and Peru have also their primitive frontagers,—and this was so in the time of the ancient Montezumas and the Incas. This juxtaposition of civilization and savagery is one of the characteristic facts of American ethnology, as it was once likewise of the history of the Mediterranean area in the Old World. In both areas we meet with a large number of peoples who rose above savagery, but, for some reason or other, failed to develop high stages of culture. That the more material evidences of civilization should be so confined to the Pacific coast is, to some writers, a significant fact suggestive of Asiatic relations; but the intellectual power of such Atlantic peoples as the Iroquois and some of the Muskhogean tribes of North America, and the moderate but distinct progress made by a few of the Brazilian tribes of the Atlantic area relieve us from any such theory, environment, and historical incident in America quite sufficing to account for the phenomena involved. (See ETHNOLOGY.) Certain other resemblances and contrasts in the various aspects of aboriginal culture in America merit attention here. At the extreme north of the continent, one stock, the Eskimo, with closely related forms of speech, kindred mythology, and folk-

INDIANS

lore, similar customs and social institutions, etc., extends in a narrow line from east to west, even overflowing into Asia, while at the extreme south (much less extensive) the Fuegians, numbering altogether less than 10,000, are divided into three distinct linguistic stocks (Yahgans, Onas, Alikulufs). Eastern and northern North America, and the corresponding regions in South America, are areas of wide distributions of single stocks. The Pacific coast of America, as compared with the Atlantic, is a place where, in diverse spots, languages seem to pullulate. This region (including the narrow limits of Mexico and Central America) contained probably more independent tongues than all the rest of the continent. Indeed, within the present bounds of the State of California alone 22 such tongues are found, with several others in Nevada, and in Prof. Cyrus Thomas' list of the stocks of Mexico and Central America, made in 1902, nearly 30 are recognized.

The multiplicity of languages in primitive America has called forth explanatory theories of various sorts, among them Horatio Hale's suggestion of the origin of linguistic diversity through the spontaneous language activity of the child. As Gatschet has noted, the very existence of such a multitude of tongues all over America is proof that neither in ancient nor in later times has this continent been the scene, on a vast scale, of the suppression and extermination of peoples one by the other, which have been characteristic features of Old World history. In spite of the common belief to the contrary, mutual destruction was probably never so rife as when the coming of the white man introduced new means of warfare, and, crowding the natives for subsistence, led them to attack each other more effectively. The recent studies of Dixon and Kroeber in California have strengthened the view of a certain parallelism of language and culture.

That some culture-elements, however, have spread from tribe to tribe is shown by the distribution of certain inventions discussed by Mason, the northward movement of such plants as maize, the use of tobacco, the transmission of many themes and incidents of myths and legends (as demonstrated by Boas), the modes of occurrence of certain art-forms, etc. Interminglings of culture of a more or less local, though often of an extensive, character, have taken place in the Bering Sea area, in the Columbia River region, in the habitat of the Pueblo Indians of New Mexico and Arizona, in the southeastern part of the United States, in the Isthmian region of Central America, in Ecuador, in the Pampean country of the Argentine, etc.,—larger and more significant intermixtures have, perhaps, taken place in earlier times in Mexico, the Mayan country, Colombia, and Peru. A number of the borrowed culture-elements may be explained as the result of trade and commerce, by means of which useful or artistic objects, food, plants, etc., were easily conveyed long distances under primitive conditions. The widespread custom of adoption would also account for not a few instances of alien culture-grafts. So, too, with the exogamic marriage, when the women are culture-bearers. Where language-mixture has taken place it is more or less easily detectable in most American Indian 'stocks' and tongues. When families of the same stock possess, in the one case (Algon-

kian) dialects which differ as much as Micmac and Blackfoot, in the other (Iroquoian) as much as Cherokee and Mohawk, we are justified in looking for culture-differences as well in such widely separated peoples. Doubtless the results of careful somatological, sociological, and other investigations of the various tribes of American aborigines will furnish us ultimately with diverse ways of classifying them. At present, however, the most serviceable classification is a linguistic one, the result of the labors of Major J. W. Powell and the Bureau of American Ethnology, supplemented by the work of Dr. D. G. Brinton.

Linguistic Stocks.—The Bureau of American Ethnology has issued the Powell map showing the extent of the 58 linguistic stocks north of the Mexican boundary line; that is, of families or forms of speech, so independent of one another as to be catalogued as distinct stocks; apparently no more closely related than the Aryan and the Semitic families of the Old World. For South America no such authoritative map is extant. The exact number of such linguistic stocks in America has not yet been determined with certainty, but the following list probably represents the best view of the matter to-day:

1. Adaizan (Louisiana)
2. Algonkian (northeast North America)
3. Alikulufan (Tierra del Fuego)
4. Andaaquan (Colombia)
5. Arauan (northwest Brazil)
6. Araucanian or Aucan (Chile)
7. Arawakan (Central and N. E. South America)
8. Atacameñan (S. Bolivia)
9. Athapaskan (N. W. Canada, etc.)
10. Attacapan (Louisiana)
11. Aymaran (S. Peru, N. Bolivia)
12. Barbacon (S. Colombia)
13. Beothukan (Newfoundland)
14. Betoyan (Colombia-Venezuela)
15. Caddoan (Texas)
16. Calchaquian or Cata-mareñan (N. Bolivia)
17. Canichanan or Canisianan (N. Bolivia)
18. Carajan (S. Brazil)
19. Caribean (N. E. South America)
20. Cayubaban (N. Bolivia)
21. Charruan (N. E. Argentine)
22. Chetumachan (Louisiana)
23. Chiapanecan (Central America)
24. Chibchan (Colombia and Isthmian region)
25. Chimakuan (Washington)
26. Chimarikan (California)
27. Chinantecan (Oaxaca, Mexico)
28. Chinookan (Washington)
29. Chiquitan (N. Bolivia)
30. Chocoan (N. W. Colombia and Isthmus)
31. Chumashan (California)
32. Churoyan (Colombia-Venezuela)
33. Coahuiltecan (Mexico-Texas, mouth of Rio Grande)
34. Coconucan (S. Colombia)
35. Copchan (California)
36. Costanoan (California)
37. Cunan (Isthmus of Panama)
38. Doraskean or Changuinan (Panama and Nicaragua)
39. Eskimoan (Northern fringe of North America)
40. Esseleonian (California)
41. Guahiban (Venezuela)
42. Guaraunian (Venezuela)
43. Guaycuran (Gran Chaco, Paraguay-Bolivia)
44. Huavean (Isthmus of Tehuantepec)
45. Iroquoian (Ontario-Erie region, with offshoot in S. E. United States)
46. Itonsaman (Bolivia)
47. Jivaroan (Peru, Ecuador)
48. Kalapooian (Oregon)
49. Karankawan (Texas)
50. Kechuan or Quechuan (Peru)
51. Keresan (New Mexico, Pueblos)
52. Kiowan (Nebraska-Wyoming)
53. Kitunahan (S. E. British Columbia, N. Idaho)
54. Koloschan (Alaska)
55. Kulansapan (California)
56. Kusian (Oregon)
57. Laman (Peru)
58. Lencan (Central America)
59. Lulean (Gran Chaco)
60. Lutuamian (Oregon)
61. Mainan (Ecuador, N. W. Brazil)

- 132. Zoquean (S. E. Mexico)
- 133. Zufian (New Mexico)

Of the stocks enumerated, 51 belong to South America and 56 to North America north of Mexico. The status of investigation is such that the number assigned to South America is approximate only, and may ultimately be considerably increased or reduced. Some stocks, like the Adaizan, Beothukan (exterminated by whites), Chetimachan, and a few of the minor stocks in South America, are extinct or nearly so. A goodly number—including, for example, many of the stocks on the northwest Pacific coast, the Texas-Louisiana country, parts of Central America and the Pacific region of South America—were or are of limited area; others, like the Eskimoan, Athapascan, Algonkian, Siouan, Shoshonean, Arawakan, Cariban, Tupian, etc., are noteworthy by reason of the extent of their domain. Some, like the Kootenay, consist of practically a single language, while others, like the Algonkian, Siouan, Athapascans, Salishan, Aztecian, Mayan, Arawakan, Tupian, Cariban, etc., have developed numerous dialects, sometimes only remotely resembling the mother-tongue. Doubtless, with the perfection of linguistic research, some changes will be made in the list of stocks, or perhaps a method of groups may be devised in which stocks showing certain resemblances other than those of a lexical na-

ture may be classed together. The studies of Dixon and Kroeber indicate the possibility of this for the numerous Californian stocks, and a similar result may be predicted for certain other regions of the continent. As said, all the American Indian stocks are far from being of the same significance, many of them having hardly any historical importance. A few words about some of the most typical and most important must suffice here.

North American Stocks.—The Eskimoan stock is noteworthy by reason of being the first of all the aboriginal peoples of America to be visited by representatives of European culture,—the Norsemen in the 10th century, etc. It is also the only primitive people who, unaided by civilized races, occupy a portion of both hemispheres, for the Eskimo stretch from Labrador to a considerable distance within the borders of northeastern Asia. They illustrate the victory of man over a difficult environment, for they are a merry and sociable people in spite of the inclement and depressing character of their arctic surroundings. They have also a marked sense of humor, as the institution of the nith-song, or settlement of disputes by public judgment of the comparative merits of the two parties in competitive singing, would indicate,—the themes of the singing being the dispute and sarcasm at the expense of the opponent. The Eskimo are also very skilful carvers and engravers of ivory, their spirited drawings of animals, etc., resembling in marked fashion the similar art-products of prehistoric man of the French river-drift, a likeness which has induced some authorities (Dawkins, De Mortillet) to assume a racial connection between these two peoples. Mason has recently suggested that these drawings owe a good deal to the contact with Europeans (introduction of iron tools, etc.), but Boas considers that their close resemblance to the bark and rock pictographs of the Indians forbids the conclusion that these drawings are of other than native origin. The unity of language, and (to a considerable degree) of custom, mythology, etc., among the various Eskimo tribes is remarkable when one remembers the extent of their distribution. The use of the Eskimo dog with the sledge, the kayak, the harpoon, the snow-house (*iglu*), and the invention of many mechanical devices, show them to be gifted with native intelligence.

The Athapascans stock is notable for the contrasts in culture and diversities of culture-capacity presented by its members. Some of the Athapascans peoples of northwestern Canada and Alaska are among the lowest types of American man, and a few of them have hardly yet come to knowledge of the white man, the advent of the fur-trader being, according to J. M. Bell, a matter of the last two or three years in part of their domain. To this stock belong also the Apaches, once the terror of the civilization of the Southwest, whose depredations, in earlier times, disturbed the peace of the native civilization of Old Mexico. It is fair to say, however, of them that individual Apaches (Dr. Montezuma, for example) shows good capacity for adopting the chief elements of white American culture. Several small tribes of Athapascans are scattered through Washington, Oregon, and California, the most noteworthy being the Hupa, on Trinity River, the "Romans of California," as they have been called. The Navaho, who

THE SNAKE DANCE OF THE MOKI INDIANS.

INDIANS

have assimilated to a considerable extent the culture of the whites, were good agriculturists before the coming of the Spaniards, from whom they adopted the sheep, a fact which modified their environment and their response to it. The contrast between the rude tribes of the "Barren Grounds" of Canada and the Navaho of New Mexico and Arizona is, as Horatio Hale pointed out, one of the most remarkable instances of culture-change by process of environmental variation on record. The recent loan-word *Klondike* comes from an Athapascans dialect.

The Algonkian stock, members of which were found from Labrador to South Carolina, and from the confluence of the Ohio and Mississippi northwesterly to the foot of the Rocky Mountains and the borders of the domain of the Athapascans, are of interest for many reasons. The great area over which they are spread has brought members of this stock into contact with many other Indian peoples,—the Naskopi, Crees, and northern Ojibwa with the Eskimo; the Micmacs with the Eskimo and Beothuk; the Ojibwa and related tribes of New England, New York, and Pennsylvania, the Lenapé of New Jersey, the Nanticoke, Powhatans, etc., of Maryland, Virginia, and the Carolinas with the Iroquois (who, both north and south, form an *enclave* in the Algonkian territory); the western Ojibwa, etc., with the Siouan tribes in the upper Mississippi region, and in the southern Mississippi country the Illinois and kindred peoples with the Caddoan and other stocks; the Blackfoot in the extreme northwest of the Algonkian area with the Athapascans Sarcees and the Kootenay. The aberrant Cheyennes and Arapaho (recently studied by Kroeber) belong to the Algonkian stock. Another evidence of the importance of this stock is the fact that many other stocks and tribes are known to us by names of Algonkian origin: *Eskimo*, *Athapaskan*, *Siouan*, and possibly also *Iroquoian* and *Muskogean*; *Chipewyan*, *Assiniboin*, *Mohawk*, etc. Of all the Indian stocks of North America none have made a greater impression upon the whites (French and English) than the Algonkian. This is seen when we remember that Powhatan and Pocahontas, King Philip, Pontiac, Tecumseh, Black Hawk, etc., the Indians who have appealed most to our historians, novelists, and dramatists, have all been of Algonkian lineage. This stock has also contributed to the vocabulary of spoken and written American-English some 140 words, of which many are hardly felt to be of Indian origin: *Carcajou*, *Caribou*, *Caucus*, *Chipmunk*, *Hickory*, *Hominy*, *Manito*, *Maskinonge*, *Menhaden*, *Moccasin*, *Moose*, *Mugwump*, *Opossum*, *Pappoose*, *Pemmican*, *Persimmon*, *Powwow*, *Pung*, *Raccoon*, *Sachem*, *Skunk*, *Squash*, *Squaw*, *Tammany*, *Terrapin*, *Toboggan*, *Tomahawk*, *Totem*, *Tump*, *Tuxedo*, etc. A people who have contributed to such a cosmopolitan tongue as English important words like *Caucus*, *Mugwump*, *Tammany*, and *Totem*, deserve more than passing mention. Our civilization owes to them also more material things than these,—tobogganning and lacrosse, canoeing (in large measure) and numerous devices of agricultural and domestic industry adopted by the early colonists from the aborigines. From the Algonkian Indians the whites also learned how to make maple sugar and maple syrup. (See AMERICANS.)

The Iroquoian stocks are famous through the confederacy of the "Five (afterward Six) Nations" and the great "League of the Iroquois" (so sympathetically studied by Morgan). Their physical characteristics at the time of the war of 1861-5 were "such that they exceeded the recruits of all other races (white included) in points of excellences demanded by military requirements. The high position occupied by woman among the Iroquois lifts them above many of their Amerindian kindred. The story of the Iroquoian statesman of the 16th century, Hiawatha, and his founding of the League that was to end all war and unite all the nations in one lasting bond of peace is a historical fact, which Longfellow's confusion of the Iroquoian patriot with the Algonkian demi-god Manabozho cannot altogether obscure. In political and social organization the Iroquoian tribes attained a position that was largely *sui generis*. The tale of their long struggle to preserve their independence against the whites will be found in Morgan and Parkman, while the Jesuit Relations contain their reaction to the efforts of the missionaries to convert them to the Christian faith, as well as the account of the fratricidal strife resulting in the extermination of the Hurons. The fame of the Iroquoian tribes (for example, Mohawks) as fierce warriors has caused the general public to neglect them in other respects. Through the researches of Horatio Hale and others it has been shown that the Cherokee of the Carolinas (recently so well investigated by Mooney) belong to the Iroquoian stock, together with several minor tribes in the south Atlantic region. This stock has produced a number of eminent men: Hiawatha (q.v.), Red Jacket (q.v.), Joseph Brant, and Dr. Oronhyatekha (q.v.), the present head of the Independent Order of Foresters; J. N. B. Hewitt, of the Bureau of American Ethnology at Washington, is also of Iroquoian blood. Sequoia, the half-blood Cherokee, who invented the alphabet now in use by his people, deserves mention here likewise. As compared with the prominent part played by them in the French-English and colonial wars, and in the Revolutionary War, War of 1812, etc., the Iroquoian people left little impression upon the culture and the speech of the English in America,—the words from their language which have crept into our own have been originally place-names: *Chautauqua*, *Conesoga* (horse), *Saratoga* (trunk), etc. To the French of Canada they have given a few more words. In the place-names of the region about lakes Ontario and Erie (Ontario, Niagara, Erie, Cataraqui, Oswego, Cayuga, Seneca, Onondaga, Tuscarora, Oneida, Ticonderoga, Tonawanda, Genesee, Ohio, etc.) the Iroquoian peoples are generously remembered, while their Cherokee kinsmen in the south have likewise left their impress upon the topographical nomenclature of the country. In both New York and Ontario, where considerable numbers of Iroquois still live, with no immediate danger of dying out, but particularly in the latter province on the Grand River Reserve, the pagan and Christianized Iroquois have existed side by side in the same community for so long a time as to make this phenomenon, the interesting details of which have been pointed out by David Boyle, of great value to sociologists.

INDIANS

The Muskhogeon stock (Choctaws, Chickasaws, Creeks, Seminoles, etc.) as their subsequent career in the "Civilized Nations" of the Indian Territory with the Cherokee has shown, are among the most gifted intellectually of the aborigines of America. Gatschet notes as characteristic of this stock: Their color-symbolism for peace and war, their totemic system, the use of the "black drink," the doctrine of the "Master of Life," sun-worship, mound-building (some regard this stock as having been one of the so-called "Mound-Builders"), the ceremony of the *busk*, etc. This stock has had many intertribal wars, and the Creeks and particularly the Seminoles of Florida are famous for their contests with the whites.

The Siouan stock (Crows, Mandans, Assiniboin, Hidatsa, Sioux, Winnebagos, Omaha, Tuetos, Catawbas, Biloxi, etc.) are noteworthy by reason of their migration from the Atlantic slope in the region of the Carolinas to the trans-Mississippi and Missouri country, where their culture was conditioned by the presence of the buffalo and the adoption (from the whites) of the horse. Their wars with the surrounding tribes, particularly the Algonkian, and their subsequent numerous collisions with the whites (Minnesota massacre of 1862, the troubles in which Sitting Bull figured, etc.), are matter of history. The use of buffalo-skins made it possible for some of the Sioux tribes to develop pictography to a high degree. The researches of J. Owen Dorsey and Miss Alice Fletcher have shown the Omaha in particular to be gifted with a religio-social consciousness of a marked character, reflected in their name-giving and the ceremonies associated with the passage from childhood to manhood, in which individuality is much emphasized. That their capacity for producing men of ability is not confined to those of the primitive type (Sitting Bull) is indicated by the way in which individual members of this stock (Dr. Eastman, La Flesche, the collaborator of Dorsey, etc.) have responded to the stimuli of modern culture. The Dakotan federation is well remembered by the names of the twin States of the Northwest; Minnesota, Nebraska, etc., are terms of Siouan origin; while the minor place-nomenclature of the northwestern States contains a multitude of names from the same source.

The Shahaptian stock is noteworthy on account of the Nez Percés and the famous chief Joseph (still living), one of the most remarkable Indians of any age, whose "retreat" in 1877 has been compared to the celebrated march of the Ten Thousand of old.

The "Pueblos" Indians, as they are called from their village life, have risen in New Mexico and Arizona above the stage of savagery into a state of semi-civilization, representing the triumph of man over the adverse conditions of the desert and the inroads of fierce enemies of the lowest culture. Their relations to the so-called "Cliff-Dwellers" has been the subject of some ethnological speculation. (See PUEBLOS.) The diversity of culture among the Pueblos is not as great as that of speech. Besides the Moqui or Hopi, who belong to the Shoshonian stock, there are found in the Pueblos group three other distinct linguistic stocks,—Keresan, Tafoian and Zufian. The Pueblos culture has apparently been developed independently in several local centres, and the studies of Bandelier, Hodge,

Fewkes, Cushing, etc., have thrown much light on the origins and interrelations of stages of culture largely the reflex of environment.

The Shoshonean or Uto-Aztec stock offers the most wonderful contrasts in its members of any Amerindian stock. Linguistic and other evidence appears to justify the conclusion that not only certain peoples of the Sonoran country (Cahitas, Coras, Tepehuans, etc.), some of whom achieved a sort of half-civilization in contact with their more cultured neighbors, but the Bannacks, Shoshones, and Utes (even the wretched "Root-diggers") are kith and kin with the ancient Aztecs upon whose civilization Cortes intruded, and the tribes of Nahuatl lineage who carried that culture more or less from central Mexico to beyond Lake Nicaragua. The change from the low type represented by the Utes to the high type of the old Mexicans may have been due in large measure to environment. Intermediate stages are represented by some of the Sonoran tribes. The Mexican or Aztec branch of this stock has furnished to English and other civilized languages a number of interesting and valuable words: *Axolotl, chocolate, coyote, cacao, tomato, ocelot, chilli, copal, chinampa, jalap*, etc. The Moqui group of the Pueblos Indians belong also to the Shoshonean stock.

The Mayan stock (Cakchiquels, Huastecs, Tzotzils, Kekchis, Quiché, Tzendals, Mayas, etc.), creators of the civilization destroyed by the Spaniards in Central America, left, besides graven monuments in large numbers, other evidences of their having invented a system of "writing," which is the nearest approach by any of the aboriginal peoples of America to a phonetic method of record,—the solution of the Mayan hieroglyphics is perhaps the question of American archaeology. Their calendar-system, nagualism in religion, and the important role of woman in religious and social functions, deserve especial notice. The recent explorations of the Peabody Museum (Cambridge) have resulted in many new discoveries.

Central and South American Stocks.—The Chibchan stock, whose culture varied from that of the savage Arawacs of the mountains of Sta Marta to the civilization of the country about Bogota represent a rise from barbarism independent of that to the south in Peru, etc. There is some reason to believe that the "gold-culture" of the Chiriquí country and allied remains in the same region to the borders of Nicaragua may be due to the Chibchan stock,—the Talamanca, Guaymi, and a few other dialects of Costa Rica, etc., show affinities with Chibchan tongues. Their use and working of gold were of a high order, but neither in architecture nor in pictography could they compare with the Peruvians, the Mexicans, and the Mayas. They had a characteristic hero-legend of Bochica, and a tale of the great flood. The shrine of Lake Guatavita was a famous religious resort. Some of the famous "El Dorados" were in their territory. The Quechuan stock, which is best known through the civilization of the Incas, superimposed upon an older, widespread culture, represents but one phase of higher human activity in the Peruvian area. The extension of Quechuan language especially von Tschudi and Brinton agree in attributing not to the military achievements of this people, which antedated the

AMERICAN INDIANS.

A GROUP OF UTE INDIANS.

INDIANS

coming of the Spaniards by only a few centuries, but to intellectual and culture influences millenniums old. The marks of their language can be traced from near the equator on the north to the Pampean tribes on the south. Common in the Peruvian area seem to have been a highly developed agriculture (stimulated, as in the southwestern United States, by the necessity for irrigation and artificial treatment of the soil),—maize, tobacco, potatoes, cotton, etc., the breeding of the llama and the paco, the making of pottery (useful and artistic), metal-working of a fine and ingenious sort, stone architecture more massive and imposing than artistically beautiful, or of the highest order as regards decorative art. The Inca form of government was never probably so far removed from the system common to most of the American stocks as some writers have believed. The Incasic conquest has caused the Peruvians to be styled the "Romans of America," but the analogy is misleading. Beyond the use of picture-writing and the employment of the quipu (knotted colored strings) for purposes of record, the Peruvians had not advanced, and the semi-phonic system, like that of the Mayas, was not developed by them. Ancestor-worship and sun-worship (state religion) were professed by the Peruvians, but the most far-sighted of their thinkers touched almost upon monotheism. The hero-god of the Peruvians was the sea-born Viracocha, about whom centred a rich and imaginative mythology. The mixture of races in the production of ancient Peruvian culture is indicated by the diversity of cranial type among the skulls from the old burial grounds and mummy-caves. North of the Quechuas, on the coast about Trujillo, were the Yunca-Chimus, etc., whose civilization is represented by the ruins of Gran Chimu and other remains in the valley of Trujillo, which preceded the period of Inca domination. Southeast of the Quechuan culture was that of the Aymaras on the Andean table-lands. To them are usually assigned the ruins of Tiahuanaco, near Lake Titicaca, which in their completeness were probably the most imposing structures raised by the hand of aboriginal man in America,—in architecture they differ in several notable ways from the buildings of Inca origin. Dr. Uhle has very recently sought to show the "succession of cultures" at Pachacamac, Trujillo, and their relations to that of Tiahuanaco. The Peruvian tongues have furnished modern English, etc., many words: *guano, condor, alpaca, pampa, paco, llama, coca, quinine, jerked (beef), vicuña, etc.*

In the northern part of the Argentine Republic (Province of Jujuy, etc.) the architectural and archaeological remains brought to light by recent investigators (Ambrosetti in particular) indicate the presence of a "civilization,"—village life in a desert environment, offering striking analogies with the culture of the Pueblos Indians of Arizona and New Mexico. This Calchaqui culture is evidently much more than the mere reflex of Quechuan-Aymaran conquest which it was formerly considered to be. Its origin and growth, however, remain to be clearly demonstrated.

The Araucanian stock, whose language has been studied by Lenz, are famous for their long resistance to the Spanish arms (the story of the "conquest" has been written in the last few years by Guevara), part of which

gave rise to De Ercilla's epic of 'La Araucana.' To the Araucanian stock belong tribes on both sides of the Chilean Andes and a number of the nomadic peoples of the Pampas, where they seem to be intruders rather than aborigines. Chilean Spanish has borrowed many expressive terms from Araucanian.

The Patagonians, Tzene, or Tehuelche, famous since the time of Pigafetta as "giants" (many of them exceed six feet and some are said to reach seven). To them belongs the "Setebos" of Shakespeare's 'Tempest.'

The Tapuyan stock of Brazil is looked upon by some authorities as the oldest people of the continent—some would affiliate with them the Fuegians, in this respect—representing a race once inhabiting a great part of South America. The man of the caves of Lagoa Santa and the man of the remarkable *sambaquis* or shell-heaps of the Brazilian coast are by many authorities considered to have related to the Tapuyans. Characteristic modern Tapuyans are the Boto-cudos, so called from the labret they wear in the lower lip. According to Ehrenreich, some of these ancient men of Brazil show affinities with prehistoric man of eastern Europe.

The Tupian stock (or Tupi-Guaranis, as they are also called), whose language was much used by the missionaries for general intercourse with the natives and is the basis of the *lígoa geral*, or "common language" of the region of the Amazons, were perhaps the highest in culture of the Brazilian tribes, having the elements of agriculture, village life, pottery (well developed and rather artistic), urn-burial, etc., but nothing beyond the Stone Age. Intermixture with both whites and negroes has taken place in the Tupi area, and the rich and imaginative tales of animals, etc., belonging to Tupi mythology have thus been given a wider extension, while negro and white influences have made themselves felt, both on the language and the literature of these people. According to Hartt, the Tupi language has influenced the Portuguese of Brazil quite as much as has the latter the former. Tupi-Guarani speech has furnished to the various European tongues a considerable number of words—to English, *ipecauana, jaguar, tapioca, tapir, toucan*, etc.

The Caribian stock were long famous for their cannibalism (the word *cannibal* is a corruption of one of their ethnic names), real and attributive, and their skill in making and using canoes. The shaman, or medicine-man, had great power among them, and they practised the curious and remarkable custom of the *couvade*. Rock-inscriptions and pile-dwellings are found in their territory. Some of them have been reduced to sad straits by the contact of the whites, but some of the Venezuelan tribes of this stock are still good, typical representatives of the American Indian.

The Arawakan stock, through its representatives (the Bahamian Lucayans, the natives of Haiti, Porto Rico, Cuba, etc.), was the first of the aboriginal peoples of the New World (exclusive of Greenland and Labrador) to come into contact with the white race, and likewise the first to come under its devastating influence. Many of the tribes of this stock were of a mild and gentle disposition, good agriculturalists, pottery-makers, workers in stone, wood and gold, and excellent canoe-men (the word *canoe* comes from an Arawak dialect). They were

INDIANS

users of cotton, and to them we owe the first Indian invention adopted by the whites (*hammock*, both name and thing are Arawak). From the Arawaks, too, the Spaniards first learned the use of tobacco. Like the Caribs they practised the *couvade*. The name of the stock is said to mean "flour-eaters," on account of their use of cassava, which has also passed over to the white. The Arawak and Carib stocks have furnished to English and to the other civilized languages of Europe a large number of important words, the exact ethnic distribution of which is not easy to determine with exactness: *Agouti*, *anotto* (and French *roucouyenne*), *barbecuc*, *cacique*, *caiman*, *cannibal*, *canoe*, *cassava*, *colibri*, *hammock*, *hurricane*, *iguana*, *macaw*, *maize*, *manati*, *potato*, *tobacco*, etc. And with these names has gone the use of many of the things indicated and made known for the first time to Europeans. The debt of the Spanish and Portuguese settlers of South America and the West Indies is in these respects very great, for, naturally new fruits, plants, trees, etc., and many of their products came to be known by their aboriginal names or by corruptions of them. Thus a number of "balms" and "balsams" and other medicinal products retain in the pharmacopeia names of American Indian origin—*copaiba*, *tolu*, etc. Timber-trees, ornamental and dye-woods, have also largely kept their native appellations throughout Central and South America—the list would run into the hundreds. Large also is the catalogue of birds and other animals bearing Indian names.

Original Habitats.—The question of the original habitats of the important aboriginal stocks is one of the most interesting in American ethnology and archaeology. The researches of Rink and Boas in particular seem to have demonstrated that the primitive home of the Eskimo was in the region west of Hudson Bay, whence they spread northward and westward to Alaska, etc., and eastward (north and south) to the Arctic islands, Greenland and Labrador. See ESKIMOS.

The earliest habitat of the Athapascans was in northwestern Canada, to the westward of the home of the Eskimo. From there they migrated over the lake country, across the Rockies to the southward, leaving colonies along the Pacific to northern California, and sending out, through Arizona and New Mexico to the borders of the Nahuatl territory, the important branches of the Apaches and Navaho—the raids of the Apaches often reaching far into Mexico.

The original habitat of the Algonkian stock was, as Brinton and Hale have assumed, "somewhere north of the St. Lawrence and east of Lake Ontario," while that of the Iroquoian lay "between the lower St. Lawrence and Hudson Bay." The final result of the migrations and wars of these two stocks was to leave the Iroquois of the Ontario-Erie country entirely surrounded by Algonkian tribes. From their primitive home the Algonkian sent out numerous branches west, south, southwest, etc., making the extent of territory covered by them very large, and bringing them into immediate contact with many other Indian tribes and with the white settlers over a vast area. The Iroquois (in the Cherokee and the kindred tribes of the south) had branches, which were so separated from their northern kin as to be long taken for non-Iroquoian peoples.

The Muskogean stock, according to Gat-schet, have been from time immemorial inhabitants of the country between the Appalachian Mountains, the Atlantic, the Gulf of Mexico, and the Mississippi. The scene of their earliest development was in the neighborhood of the Mississippi, or possibly even beyond it.

The chief migrations of the Caddoan (Pawnee) peoples have taken place in historical times northward and southward from the Platte River, from which region they expelled in part the Siouan tribes, etc. If their own traditions are reliable, their primitive home lay farther to the south, on the Red River of Louisiana.

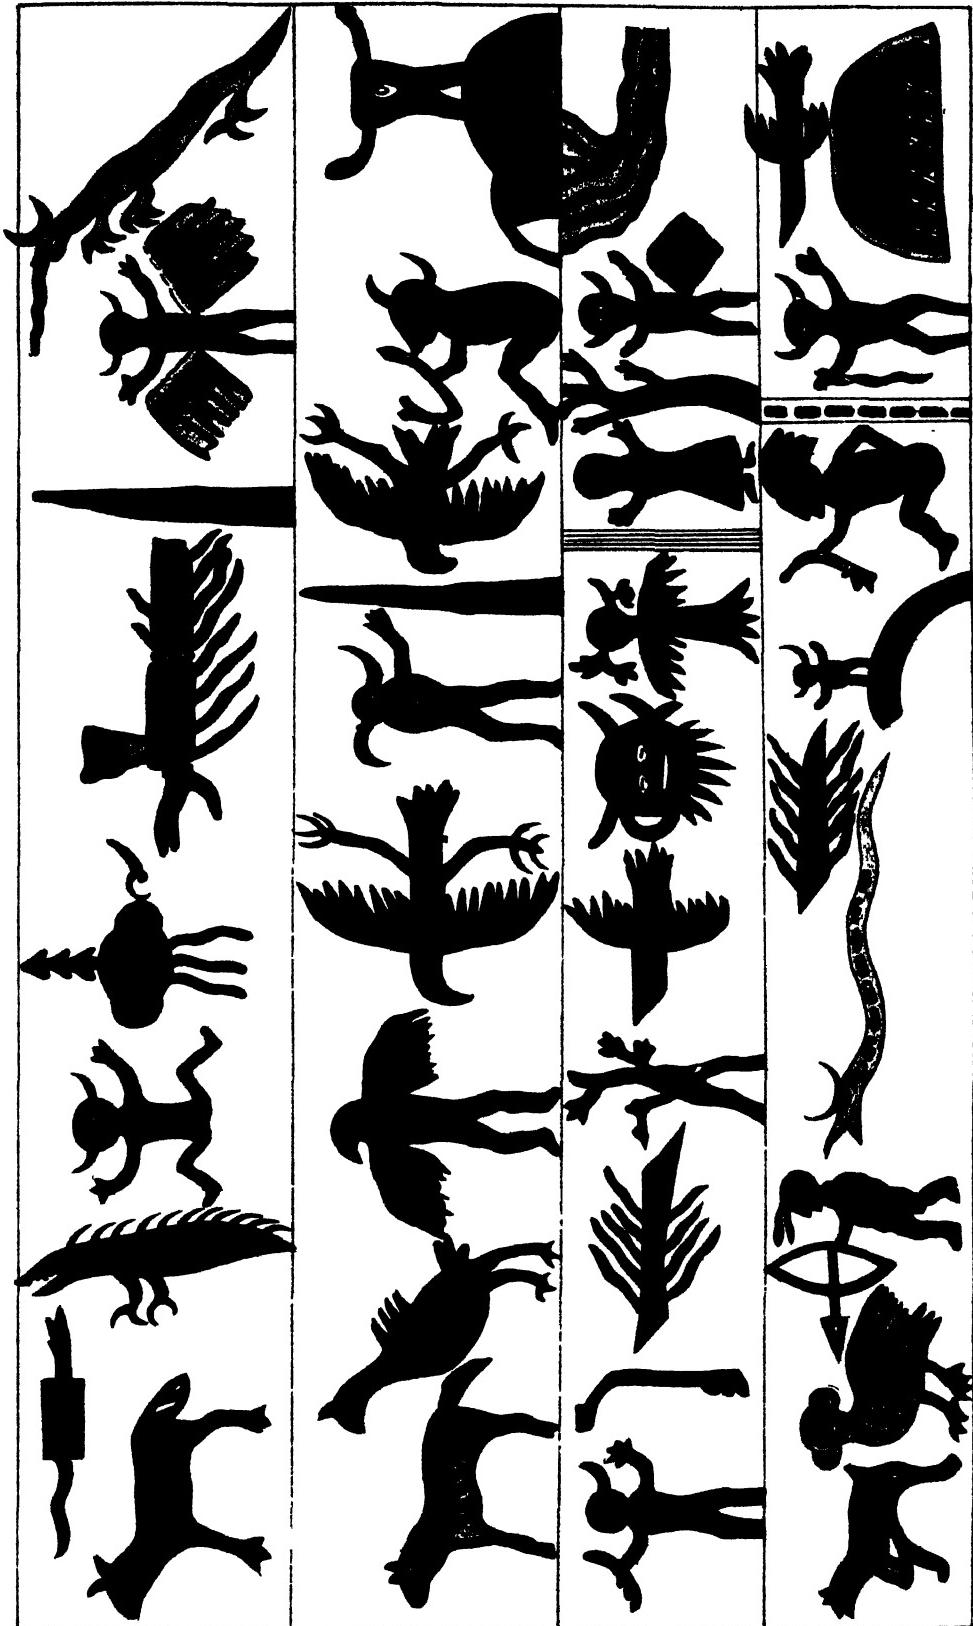

The primitive home of the Siouan stock (characteristic Plains Indians since the introduction of the horse) was eastward in the region of the Carolinas. This fact has been revealed by the study of the Tutelo and Catawba languages belonging to this eastern area, and by inspection of the traditions of the various Siouan tribes. The main bodies of Siouan migrants followed the Ohio and the Missouri far to the north and west; the Mandans, Assiniboins, etc., reaching to within the borders of Canada. Other minor bodies traveled to the southwest, their representatives still existing in the Biloxi, etc., of southeastern Mississippi. The Siouan tribes seem to have followed the buffalo in its retreat westward, and their migration from the Carolinas is of considerable sociological interest. At one time their trans-Mississippi habitat included practically all the territory between the Arkansas and the Saskatchewan from the great river to mid-Montana, with the Winnebagoes jutting out on Lake Michigan. Their forays and trade-excursions led some of them from time to time across the Rocky Mountains—the present writer, in 1891, met a friendly party of them far within the Kootenay territory.

The original habitat of the Shoshonean or Uto-Aztecán stock, which embraces the Ute, the Sonoran, and the Aztecán (Nahuatl) peoples, and has representatives from the north of Idaho to the Isthmus of Panama, was probably somewhere in the northwestern section of the United States. The primitive home of the Shoshonean section was "somewhere between the Rocky Mountains and the Great Lakes," and the traditions of the other two branches bring them from the far north, as compared with their present southern abode.

The Mayan stock, creators of the civilization of Central America, according to their own traditions, came from somewhere to the north—the position of the Huastecan branch of this stock north of Vera Cruz suggests that the Mayan emigrants from the home-land skirted along the Gulf of Mexico from some region considerably to the north.

The Arawakan stock (including the natives of the Bahamas and the Antilles, except the intrusive Caribs) had an extension in South America comparable only to that of the Algonkians and Athapascans in the northern half of the continent,—from the high Paraguay to the Goajiran peninsula in Venezuela, and in its greatest expansion from the Xingú to the Amazon and Orinoco. Its primitive habitat was in some part of the Brazilian interior, probably between the Xingú and the Paraguay, the general trend of their migrations having been northward. The Cariban stock, another very extensive people, who at the time of the Colombian

PICTURE WRITING OF THE OJIBWAY INDIANS.

INDIANS

discovery were to be found in the smaller West Indian islands, and the northern part of the continent from the Essequibo in Guiana to about the Isthmus of Panama, came originally, as the presence of the Carib Bakairi on the Xingu indicates, from the high interior of Brazil, at the sources of the Xingu and Tapajos.

The Tupian stock were widely extended at the time of the discovery along the Atlantic coast region from the La Plata to the Amazon, with branches scattered along the Paraguay and the Madeira to the foot of the Andes. Their primitive home, Brinton, with reason, assumes to have been in the central highland country to the east of Bolivia. The general direction of the earliest migrations of this stock was therefore southward (down the Paraguay to the Atlantic), after which the Tupi branch followed the coast to the Amazon. The Tapuyan stock, who once occupied the region between the Xingu and the Atlantic coast (from the latter they have been driven by the Tupis), are probably the oldest human residents of part of this area, their tenure of the seacoast reaching far back into prehistoric times.

The Chibchan stock, to which was due the civilization of the Bogota region of Colombia, had their original habitat in the Andean highlands of central or southern Colombia, whence they wandered northwest into the Isthmus of Panama and northeastward up the Magdalena.

The Quechuan stock, authors of the most remarkable of South American civilizations, according to their own traditions spread from very small beginnings in the country about Lake Titicaca; but von Tschudi and Brinton, for linguistic reasons chiefly, find the primitive home of this people to have been in the extreme northwest of their characteristic area. The Aymara stock, which some authorities consider to have been a branch of, or perhaps an older member of the Quechuan, had its original habitat to the southeast of the latter. The relation of the Aymaran stock to that which produced the Calchaqui civilization of the northern Argentine is not clear.

Language and Writing.—Although the languages of the American aborigines constitute so many independent families of speech, the vocabularies of which are entirely divergent one from another, nearly all (if not all) of them possess certain general grammatical characteristics which justify us in classing them together as one great group of human tongues. Brinton enumerates as points of resemblance: Development of pronominal forms, fondness for generic particles and for verbs over nouns, and incorporation,—the inclusion of subject or object (or both) in the verb, etc. Most American Indian tongues may be called "holophrastic," from the practice of compressing a whole "sentence" into a "word," the length of which is sometimes very remarkable. As an example may be cited the Micmac (Algonkian) *yáleolemáktawcpokwóse*, "I am walking about carrying a beautiful black umbrella over my head." This word, according to Rand, is derived from *pokwósón*, "an umbrella"; *máktawde*, "I am black"; *wolæe*, "I am beautiful"; *yále*, "I walk about." From the Kootenay language may be cited: *Nátlámkiné*, "he carries the head in his hand" (*n*, verbal particle; *atl*, "to carry"; *tlám*, composition form of *aaktlám*, "head"; *hin*, "to do anything with

the hand"); *iné*, verbal); *hinúpqañapiné*, "thou seest me" (*hin*, "thou," (subject pronoun); *upqa*, "to see"; *dp*, "me" (object pronoun); *iné*, verbal). As typical incorporative languages the Iroquoian and Eskimo may serve. All the incorporate forms of speech in America do not, however, proceed upon identical lines; and some that do incorporate, like Kootenay and Eskimo, often have one or more cases. According to Dixon and Kroeber many Californian languages do not possess the feature of incorporation at all (such are, for example, Maidu, Pomo, Yuki, etc.). As types of incorporating languages less complete than Iroquoian we have Kootenay, Siouan, Aztec. Some of the Central and South American tongues seem also to have little incorporation. Otomi and Maya appear to be evolving in somewhat the same direction as modern English, away from incorporation and grammatical plethora. Many of the Amerindian tongues are both prefix and suffix languages; others prefer prefixes, others, again, suffixes. Some possess, and some do not, a plural form for nouns; a dual; gender-distinction in pronouns; a high development of demonstratives; reduplication; syntactical cases, etc. A few possess grammatical gender and some exhibit differences in the words used by men and women. In the matter of phonetics the languages of the American aborigines are remarkably divergent, some being extremely harsh, guttural and consonantic, others equally smooth, soft, and vocalic. The absence of certain consonant sounds and the equivalence of certain vowels and consonants characterize some forms of American speech. Euphonic changes are of major or minor importance. Sentence-construction differs greatly in various tongues. The position of the adjective is not always the same. The Haida language has even a distinction like that between our *shall* and *will*. Careful investigation of the many Indian languages, as yet studied imperfectly, if at all, may reveal other interesting linguistic phenomena. How much has been written about and in some of the languages of primitive America may be seen from the bibliographies of Pilling! Our knowledge of them varits from a brief vocabulary of the Esselenian to the exhaustive dictionary of Yahgan compiled by Bridges. The native literature runs from the unrecorded tales of the northernmost Athapascans to the poetry of the ancient Mexicans and Peruvians, some of which has been handed down from pre-Columbian times. The only actually phonetic (syllabic) alphabet now in use among the Indians (except the syllabaries introduced by missionaries among the Athapascans, Crees, etc.) is post-Columbian,—the invention of a half-blood Cherokee. A sort of alphabet has, however, sprung up more recently among the Winnebagos. The development of picture-writing varied very much among the numerous tribes, as may be seen from Mallery's classic study of the subject. Sometimes, as is the case with the Kootenays, ability to draw does not seem to have been accompanied by exuberant pictography. The Walum Olum of the Delawares, the "calendars" of the Kiowa, Sioux, Pima, etc., are special developments of primitive records, the highest form of which is seen in the manuscripts ("books") of the Aztecs and Mayas of a religio-historical character. The pictographic records of the Ojibwa "medicine men" have been studied by

INDIANS

Hoffman, and the rite-literature of the Cherokee by James Mooney. The native literature of primitive America has been the subject of special monographs by Dr. D. G. Brinton. The Spanish-American countries have furnished several writers and investigators of Indian descent.

Religion.—The mythology and religion of the American Indians have received particular treatment at the hands of Müller, Brinton, Powell, etc. Perhaps the most general myth of importance is that of the divine hero, teacher, and civilizer, who after accomplishing his labors, leaves the earth, promising to return at some future time. This myth is found in Mexico (Quetzalcoatl), Yucatan (Kukulkan), Colombia (Bochica), northeast North America (Manabozho, Glus-kap, etc.) Somewhat analogous is the myth of the twin reformers of the primitive world among the Pueblo Indians, Navahos, etc. The Iroquoian stock have the myth of the contest of the good and the bad mind. The Algonkians have a myth-cycle of the rabbit, the tribes of the northwest Pacific coast one of the raven and thunder-bird, the Rocky Mountain peoples one of the coyote, the Brazilian Indians one of the jaguar, etc. Some of the tribes are very rich in animal myths and, as Mr. Mooney asserts, the characteristic tales of "an 'Uncle Remus' nature" found among the Cherokee and other peoples have not, as many suppose, been borrowed from the negroes of the South. Even the famous "tar-baby" tales have their independent Amerindian analogues. Flood-legends are widespread in America and vary from the simple, locally colored stories of rude Athapascans to the elaborate conceptions of the civilized peoples of Mexico, Central America, etc. The cardinal points and the number four have developed with many tribes a rich symbolism, with which the chief colors are often connected.

The "medicine men" of the Ojibwa, the Cherokee, the Apache, have been investigated by Hoffman, Mooney, and Bourke, and a large amount of accurate and authentic information concerning shamanism among the Amerindian peoples has been accumulated. The power of the "medicine man" varies much from tribe to tribe,—with some he is a personage of little or no importance; with others he is the controlling influence in secular as well as in religious affairs. The acme of such influence is found among some of the tribes of Guiana and Brazil. These "medicine men" had often their secret societies and "lodges" into which chosen neophytes were admitted with appropriate ceremonies. They had also, with many tribes, the control of the rites to which the youth were subjected at the time of puberty, with others they performed such marriage ceremony as existed. Besides these shamans, there were "prophets" and religious reformers, especially since contact with the whites. The widespread "Ghost Dance," in its more recent outbreaks, has been studied in detail by Mooney. Worthy of note is also the "new religion" of the Iroquois, and the "Shaker" religion of the Indians of Puget Sound. The investigations among the Pawnee by Miss Fletcher and G. A. Dorsey have demonstrated the existence of a relatively high form of primitive religion in a rather unexpected quarter,—their worship of the morning star in connection with agriculture was, however, at one time accompanied by human sacrifice. The mortuary rites of the American Indians, corresponding to

diverse ideas of the soul and its future in the other world, varied from simple neglect of the corpse to what is represented in material form by some of the mounds of the Mississippi Valley and the stone tombs of Peru. The mortuary customs of the aborigines of North America have been made the subject of a special monograph by Dr. Yarrow, and the doctrine of "animism" among the South American peoples has been treated at length by Koch. The contemplation of the *totem* (properly Ojibwa *odewma*)—tribal or family mark,—of certain Algonkian tribes has given rise to theories of "totemism," concerning which there is much dispute in the world of science. "Fetishism," as exemplified in the Zuñis, has been investigated with some detail by Cushing. Cannibalism (the word *cannibal* is the corrupted form of a South American tribal name) has been rarer in America than is generally believed. Outside of its occurrence through necessity in ways known to civilized peoples, it was chiefly partial and ceremonial. Epicurean cannibalism flourished along the coast of South America and on some of the Caribbean islands; ritual cannibalism among certain tribes of the northwest Pacific coast, in ancient Mexico, etc. The almost extinct Tonkaways of Texas have the reputation of being the "last of the cannibals," while the Attacapas owe their name to this practice attributed to them by their neighbors. In the legends of the Cree and Ojibwa tribes of the Algonkian stock, a cannibal giant (wendigo) figures, and a horror of human flesh eating is expressed at the present time, whatever may have been the case in the past. From the condition of human bones and other remains in the shell-heaps of various parts of the coast, some authorities have come to the conclusion that cannibalism did exist in prehistoric ages among some of the Indian tribes. Religious ideas approximating to monotheism are attributed by some chroniclers and investigators to some of the more enlightened aboriginal rulers of Mexico and Peru. In these regions of the continent, as also in Central America, architecture and the arts of commemoration and record were at the service of religion. See *MYTHOLOGY*.

Amusements.—The games of the American aborigines, some of which, like lacrosse, have passed over to their conquerors, are of sociological and religious significance in many instances. Stewart Culin has made a special study of the games of the North American Indians, and rejects the theory favored by Tylor and others, that many of them (for example, Mexican *patollis*), are imports from Asia. The games of the civilized Aztecs seem to be but "higher developments of those of the wilder tribes," and those of the Eskimo are modifications of games found among other aboriginal peoples of America. Among characteristic Amerindian games may be mentioned: The gambling game with sticks, the hoop-and-pole game, the ball-race of the southwestern United States, the ball-games of eastern North America, the woman's game of double ball, foot-races, the snow-snake, etc. Culin holds that back of every game lurks "a ceremony in which the game was once a significant part." The variations in games do not follow linguistic lines. One centre whence games have radiated and where some of their oldest forms are still to be found, is in the southwestern United States, from which their migrations can

STONY INDIANS WEARING RICH OTTER AND ERMINE TROPHIES.

INDIANS

be traced north, northeast, east, and south. Interesting modifications arise from conditions of environment.

Arts and Inventions.—The arts and inventions of the American Indians correspond to the extent and variety of their environment. The mass of the inhabitants of the continent at the time of its discovery were hunters and fishers, or agriculturists of the Stone Age, most of whom had some knowledge of pottery-making. The house followed the lines of climate and culture, from the snow *iglus* of the Eskimo and the rude *wickiups* of the Utes to communal houses of the Mohegans, the Iroquian "long-house," phalansteries of the Pueblan and Central American areas, and the stone dwellings of a more or less pretentious sort of the civilized peoples of Mexico, Central America, and Peru. The cavate lodges and cliff-dwellings of Arizona and New Mexico, the wooden (sometimes underground) houses of the northwest Pacific coast, the skin-tents of the plains tribes and the wigwams of the Algonkians, the earth-lodges of the Mandans, etc., correspond to environmental stimuli. A like variation may be seen in the cradles of the American aborigines, studied by Mason, and in their means of transport on the water,—kayaks, "bull-boats," woodskins and balsas, dug-outs, canoes of pine and birch bark, large and small, and of all varieties of design and finish. In North America the Algonkians and Iroquois, and in South America the Indians of the great Brazilian water-ways, have made themselves celebrated for their skill in navigation. So too has the Eskimo with his kayak and the Peruvian with his balsa. The Algonkian Etchemins are literally "the canoe-men." The seagoing canoes of the fishing tribes of the coast of Alaska and British Columbia also deserve mention. On land some of the American Indian tribes have used the dog (Eskimo in particular) and the sled (the Algonkian toboggan, adopted by the whites for amusement purposes, is a special form), while in Peru the llama has been employed for ages for "packing," but not for draft purposes. The use of the horse and the modifications of primitive culture thereby induced in the Indians of the plains of the Missouri-Mississippi valley, the llanos of Venezuela, the pampas of the Argentine, etc., are, of course, post-Columbian. So, too, the influence of sheep culture upon the Navaho and their primitive industries, and of the cow among certain South American tribes. The only animals domesticated by the Indians whose use amounted to a considerable factor in their social and religious life were the dog and the llama, the latter in Peru and Bolivia only. The other half-domesticated animals and birds are of little importance as culture elements. The domesticated dogs of pre-Columbian America represent several diverse species of *Canidae*. The absence of such domesticated animals as the cow, the horse, the sheep, etc., in pre-Columbian America accounts for certain limitations of its culture as compared with that of the Old World. Pets, however, bird and beast, were very common, specially in Brazil and Guiana. The disappearance of the wild buffalo and other animals of the chase, since the coming of the whites, has been fateful for some tribes,—the contact with the latter as represented by the various "fur companies," etc., has caused many changes in the life of the aborigines, seldom for the better.

As Mason has pointed out, the Amerindian traps and other devices for the capture of wild animals indicate intellectual skill and marvelous adaptation to the habits and actions of these creatures. The Eskimo harpoon and its appurtenances, the simple and composite bow, the arrow-poisons of some North American and many South American peoples, the manufactures of obsidian and jade in ancient Mexico, cotton weaving and dyeing in the more southern regions, maguey-paper making in Mexico and Central America, stone carving (from Mexico to the Argentine), feather-work (in the southern United States, Mexico, Central America, and parts of South America), gold working (in the Isthmian region, Colombia, etc.), the hammocks of the Venezuelan tribes, the fish-poisoning devices of many peoples of South America in particular, the fine pottery of many regions of the continent, the *quipus* or knotted record-strings of the ancient Peruvians, the primitive drum-telephone of certain Brazilian Indians, the blow-gun (southeast United States and South America), cassava preparation (northern South America), the bolas of the Pampean tribes, etc., represent the diversity of invention and manufacturing skill among the American aborigines. The lamp of the Eskimo and some of the Indian tribes of northwestern North America is *sui generis* (its importance has been emphasized by Hough). Methods of computing time, season, etc., vary from the slanting stick of the Algonkian Naskopi to the elaborate calendar systems of Mexico and Central America. Of musical instruments, the drum, the flute, the pan-pipe, and the "musical bow" were known to the American Indians. Songs and dances to the accompaniment of these were in vogue. Practically all stages of primitive culture were to be found in pre-Columbian America, if we may judge from the tribes now surviving, from the savage Seris to the ancient Mexicans, Mayas, and Peruvians. Moreover, within the bounds of the same linguistic stock, as noted above, there may be found tribes representing a high and a low stage of development; as for example, the Aztecs and the Utes of the Shoshonean stock, the Dogribes and the Navahos of the Athapascans, etc. Some tribes were pre-eminently fishers, others hunters. Many excelled in both, like the Eskimo and some of the peoples of the northwest Pacific coast. Some sort of agriculture was widespread in America—the cultivation of corn, beans, varieties of pumpkin and squash, etc., was known all over eastern North America, and the regions of the southwest, etc.; and typical tropical and semi-tropical and other plants and fruits (potato, tomato, maize, pineapple, tobacco, varieties of cotton, manioc, sweet-potato, cacao, coca, etc.) were cultivated in the more southern regions of Mexico, Central and South America. The spread of tobacco and maize in North America and of certain other plants in Central and South America indicates agricultural receptiveness on the part of the many tribes concerned. The capacity of the American Indians generally for agriculture has been underrated probably, as both the desert-born cultivation of the Pueblos Indians and the tropically stimulated cultivation of the Indians of South America indicate. The arid regions of the Peruvian coast offer another example of considerably developed agriculture. In America the utilization of the gifts of earth varied from

INDIANS

the seed picking and root digging of the Utes to the market gardens and chinampas of ancient Mexico. How the necessities of agriculture can shape a religious system may be seen from the rites and ceremonies of the Pueblos Indians, the cult of "mother corn," etc. With some tribes tobacco was more or less of a sacred plant, also the mescal.

Position of Woman.—The relation of women to agriculture gave them a higher standing with certain tribes than would otherwise have been the case. With the Iroquois the position of women was very high and to them was allotted a considerable share in the government, peace negotiations, etc., and female chiefs were by no means unknown,—women were the "mothers of the nation." Among the Mayan peoples of Central America woman's position was also high. Many of the priests were women, and they were also commonly the leaders of their tribes in rebellion against the Spaniards—the most famous was Maria Candelaria, "the American Joan of Arc," who led the insurgent Tzendals in the 18th century. In ancient Mexico and Peru the position of woman was perhaps not quite so high. Among some tribes the position of woman was very low, and her sexual peculiarities added to the disesteem in which she was held, as for example, among the Tacanan Araunas of Bolivia. The Athapascans tribes vary much in their treatment of woman,—with some she is little better than a slave or servant, while with at least one Alaskan people of this stock female chiefs existed at times. The "purification" of women at the period of their menses, and the segregation of girls at the time of puberty, were accompanied with many rites and ceremonies among various tribes from the rude Athapascans to the civilized Aztecs. The curious custom of the *cowade* (imitative child-bed on the part of the husband) prevailed among many Venezuelan, Guianian, and Brazilian peoples. The relations between environment and the share of the sexes in culture has been investigated by Mason; according to whom the zenith of virile Amerindian art is reached in Peru, while in Colombia we find woman as farmer, weaver, and potter. In the Oregon-California region one art, basket-making, reaches its acme of development in the hands of woman. A large female influence in religion is noticeable among the Pueblos Indians. Among some tribes, for example, the Hurons, the wergild for killing a woman was greater than that for a man. Some sort of matriarchal system, with maternal descent, prevailed very commonly in pre-Columbian America; among certain of the Koloschan Indians, for example, a man was considered to be in no sense related to his father, his sole parent being the mother. Besides this extreme form, numerous other varieties occur among the tribes now existing, the system in vogue among the Iroquois, etc., being more complicated and adapted to social needs. The systems of marriage known to the American Indians varied from the absence of any particular rite or ceremony to selection of the wife by the old women of the tribe, as among the Hurons, or the uniting of the couple by the "medicine men." Some of the tribes of the Brazilian forests, ranking very low in culture, are strictly monogamous; while peoples of higher civilization, like the Chibchans, Mexicans, Peruvians, etc., were polygamous or concubinative, or both. Marriage

by purchase was found over a large area of America; but here as in other parts of the globe, the "money" received was often rather a compensation to the parents for the loss of their daughter than a real sale of her to a suitor. Divorce, in many forms, is known to the primitive Americans, both by mere word of the husband and according to set forms and rites. Consanguineous marriages were strictly avoided by many tribes; but among a few, such as some of the lowest Athapascans, incest was not condemned. In the matter of the sex-relations, as in many other fields, the American Indians exhibit almost all possible phases from the monogamic chastity of some of the lowest peoples to the unnatural indulgences of the Peruvians. Runaway matches and marriages for love, in spite of the contrary opinion entertained by some authorities, have been by no means uncommon throughout the continent. Suicide on account of unsuccessful wooing by both sexes is also not at all rare. Some peoples, too, have developed love-songs of a romantic order, for example, the *yaraveys* of the Quechuas.

Government.—The systems of government of the American Indians and their tribal organizations range from the simple democracy of the Kootenays and some of the Brazilian Indians to the elaborate state institutions of the ancient Mexicans and Peruvians, which in several respects resembled the corresponding institutions of mediæval Europe or the ancient classic world. The power of the chief, however, seems everywhere to have had limitations, and some tribes distinguished the permanent peace chief and the temporary war-chief. Chiefs were generally elected, either from the body of the tribe or from certain specified families. "Totemism" and secret societies are not found to any extent, if at all, among certain tribes (the Kootenay, for example); while with many of the peoples of the northwest Pacific coast they are perhaps the chief feature of aboriginal society, as Boas has recently shown. Property rights are represented in many stages, from the semi-anarchic Eskimo to the Aztecs of Old Mexico and other peoples of Central and South America. Slavery existed among many tribes, and on the northwest Pacific coast a sort of traffic in human chattels had arisen. See *SLAVERY*.

Trade and Commerce.—Within the spheres of the culture-centres of Mexico, Central America, Peru, etc., trade and commerce were well developed. The Columbia River region was the scene of a less developed trade; while the southeastern United States, the region of the Great Lakes and country west and south of them, had also their important distributing points. The region of Bering Strait was likewise an Asiatic-American commercial centre.

Education.—With the lower tribes generally, such education as was imparted to the children was given by the father to the boys and by the mother to the girls. Peoples like the Iroquois, the Siouan Omahas, etc., used the instruction of tales, legends, and proverbs. The ancient Aztecs and some of the other semi-civilized peoples of Mexico and Central America had schools for boys and others for girls, in which the duties proper to each sex were taught under the supervision of the priests.

Physical Characteristics.—The physical characteristics of the aborigines of America mingle uniformity with diversity. The skin color, popu-

INDIANS

larly styled "red" or "copper," is designated by Mantegazza, "burnt coffee," and by Brinton "brown of various shades, with an undertone of red." This but varies from rather dark to rather light. Among the lighter tribes have been reckoned the Koloschan Tlinkit, the Bolivian Yurucari, etc., and among the darker the Charmas of the Gran Chaco, the Bolivian Canisianas, and a few other tribes of South and Central America. The hair is generally termed "black," but, as Brinton notes, there is in it "a faint under-color of red," which shows up more in childhood and seems much more prominent with certain tribes than with others. Red hair is known among American Indians, but in some cases (certain South American tribes, for example), its occurrence may be due to infusion of white blood. The eyes of the Indians are, with rare exceptions, dark brown. The stature varies from rather low to rather high, represented on the one hand by some of the shorter Brazilian tribes and on the other by the Patagonian "giants." Among the peoples presenting many individuals of tall stature, may be mentioned the Yumas and Pimas, some of the Muskhogeans, some of the Crees, Ojibwa and eastern Algonkians, Pawnees, Iroquois, Siouans, Huaveans, Ramas, some of the Cariban tribes, Yurucari, Cayubabas, Guaycuruans, Patagonians, etc. So far as is known no dwarfish people comparable to the dwarf races of the Old World existed in America, although the skeletons from certain Peruvian tombs prove the existence of a dwarfish element in the general population; and the stature of many individuals among certain Brazilian tribes is so low as to induce some authorities, with Kollmann, to predicate the former existence of a dwarf race. In the relations of trunk and limbs and in the relation of one limb to another many variations occur among the Indians, due to occupation (canoeing, etc.,—and, since the advent of the whites, horse-riding). In primitive America all the chief forms of skull (often with artificial flattening, etc.) are found. Among the dolichocephalic (long-headed) peoples are the Eskimos and Iroquois generally, some of the Muskhogeans, Otomis, Aymaras (partly), Tapuyas, and Tupis (largely), etc. Of the brachycephalic (broad-headed) may be mentioned the Araucanians, Caribs, Arawaks, Patagonians, Mayas, many of the tribes of the Pacific coast region of North America, etc. The civilized peoples of Mexico, Central America, and Peru appear to have been of stature below the average and of varied skull form tending to brachycephalic, indicating mixtures of types. In the Columbia River region type-mingling is indicated also by both stature and skull-form. The Peruvian region is another centre of race-mixture, as evidenced by skull-form. The oldest skulls discovered in prehistoric burial-places or in geological *situ* are not distinct from the American types,—the latest found, the "Lansing skull," is quite Indian. The skull capacity of the Indian is below that of the white in general, but many exceptions occur. The brains of the less cultured Indian peoples (Fuegians, Eskimos), show no decided anatomical inferiority to those of civilized Europeans. Great varieties of build and set of body are found among the American Indians, from the half-starved Fuegians to the well-fed and corpulent Iroquois. Small feet and hands are very common. Among many tribes

in various parts of the continent handsome men and women of considerable beauty are to be found. In the case of women an admixture of white blood often enhances their beauty.

Race-Fusion.—The intermingling of the American Indians with the intruding white race has been much greater than is generally believed. The extent of this fusion of races varies from certain parts of North America with their classic Pocahontas examples to Uruguay, in South America, where 90 per cent of the population are said to be of mixed blood. The Eskimos of Greenland have intermarried with the whites (Danish fathers, native mothers), so that except in the parts remote from settlements no pure-blood Eskimo exists; and the same is true of a good deal of Labrador, where the contact has been with fishermen of English descent. The Micmac, Abnaki, and related Algonkian tribes of Maine, New Brunswick, etc., have a large admixture of white blood (French fathers, native mothers), and all over Canada and the northwestern United States in the early days of colonization and exploration the French traders, trappers, *voyageurs*, and *courreurs des bois* mingled freely with the native women, particularly those of the various Algonkian peoples of the Great Lakes and the West. The Hudson's Bay Company, by introducing employees of English and Scotch descent into the Canadian Northwest, made possible other *métis*, of which those of Scotch descent on the father's side are said to be healthy and sturdy specimens of humanity, with more than ordinary capacities. As indicated by the present condition of the Iroquois on the reservations in Quebec, Ontario, and New York, some infusion of white blood has taken place from very early times. Here the combination of white mother (often an adopted captive) and native father is more common than is usual in race-mixture. The Cherokee had an admixture of white blood in ante-Revolutionary days, to which Mooney attributes much of their culture-achievement since that time. In Mexico, Central America, and South America generally, as Talcott Williams has very recently noted, the half-breed element is very large indeed, for the native population was never exterminated by the whites as some histories still teach. Of the 40,000,000 inhabitants of South America it has been estimated that less than 10,000,000 can lay any claim to pure white blood. There is reason to believe that the future of some of the South American countries will be as much in the hands of the Indians as in those of the whites. In Mexico, parts of Central America, Colombia, Peru, and Chile, the strain of Indian blood represents able and intellectual aboriginal peoples. In certain parts of South America, and sporadically in northeastern North America, intermingling of Indians and negroes has occurred, giving rise to the so-called *Cafusos*, etc., of Brazil, and a few other small groups. The mixture of white-Indian-negro is also found here and there. In some of the Spanish-American countries there is a special vocabulary to designate the numerous degrees of *métissage*. In the Canadian Northwest the half-breeds have taken a prominent part in the development of the country (one noted *métis*, Norquay, was premier of the province of Manitoba), and they are likewise noteworthy in the annals of the northwestern United States. In Mexico and Central America, not alone the *métis* but

INDIANS

the Indians themselves have produced celebrated men. Juarez, the liberator of Mexico, a really great man, was a full-blood Zapotec, and President Barrios of Guatemala a Cakchiquel (Mayan stock).

Treatment by Whites.—The ill treatment of the American Indian by the whites has often been such as to stamp with eternal dishonor the conquering race. Massacres, broken treaties, land-robbing, commercial swindles, etc., mark the path of advancing "civilization,"—English, Dutch, French, Portuguese, and Spanish have all been guilty at some time or other. The English in Newfoundland, the Americans in the West, the Castilians in northern Mexico and Yucatan, have exterminated or sought to exterminate whole tribes. We must, however, believe that the accounts of the early chroniclers concerning the "millions" of Indians slaughtered by the Spaniards, were the customary exaggerations of those who sing the victor's deeds. Peru and Mexico, for example, would not contain so many Indians to-day were those stories literally true. Against the centuries of dishonor in the treatment of the Indians by the whites, we may place the efforts of missionaries of all faiths, from the good Las Casas in New Spain to Duncan of Metlakahtla. The Jesuits among the Iroquois and Algonkians in North America, the Moravians among the Eskimo and some of the Algonkians and Iroquois, have all done good work, which only the incapacity or worse of governmental authorities has made null. The missions in California and the "reductions" in various parts of South America (Paraguay in particular) might have succeeded in keeping the Indians gentle and loyal sons of the Church had the good fathers been forever in charge, but the oncome of the more strenuous life of the whites doomed them to helplessness. The story of the Paraguayan experiment is one of the most interesting in the annals of mankind, but also one of the most disheartening. Against such failures a few bright spots may be set,—the Fuegian mission, for example; but even there all is not well. Signs of a better treatment of the Indians still within the borders of the United States are not wanting, and it is to be hoped that the present educational fads with which white children are being experimented upon will be kept far from the Indian schools.

Influence on Civilization.—The contributions of the aborigines of America to the world's stock of civilizing factors and influences are much more numerous and of greater importance than is generally thought. Besides the innumerable place-names in all parts of America of Indian origin, the Algonkian, Peruvian, Brazilian, West Indian, Guianian, Venezuelan, and Mexican words in English, French, Spanish, and Portuguese (whence many of them have spread into all the civilized languages of the world) are able remembrancers of the conquered race. The literature of the Spanish-American countries and of Brazil has been more or less affected by the stimuli of native theme and treatment. Many of the old dances and folk-customs still survive even where Christianity has been at least outwardly accepted and have sometimes been adopted by the descendants of the European colonists. The "Hiawatha" of Longfellow, and the tales and dramas based upon the deeds, adventures and romantic episodes in the lives of King Philip, Pocahontas, Pontiac, Tecumseh, etc., to

say nothing of the novels of Cooper and his successors, indicate that the Aryan mind of the Anglo-Saxon order has found treasure in the Amerindian soil. In Mexico and other parts of Spanish America the cathedrals and other religious edifices, by intention or by happy chance, often occupy sites sacred ages before the Columbian discovery to pagan deities,—so the new religion gathers strength from the old, and the dislocation of faith so common in Protestant countries is avoided to a very large extent. Of more material things, we owe largely to the Indian the paths over which our highways and our railroads run, while many of our cities and towns have only sprung up on the old campsites of our predecessors. The great importance of some of these "Indian ways" in the history of the United States has been pointed out by Hulbert. The Indians' knowledge of the great water-ways of the country, of portages and trails through forest and over mountain, has made possible colonization and settlement otherwise utterly out of the question. Indian hunters and fishers, scouts, guides, canoe-men, carriers and packers, in all sections of the American continent, have been indispensable to the progress of white civilization. Nor have Indian slaves and servants been few or without social significance in some quarters; while French, Spanish, and English have at times availed themselves of the services of Indian warriors,—the Iroquois enlisted for the North and some of the Cherokee for the South in the Civil War, and then the government has sometimes set one tribe off against another. In Canada and part of the northwest of the United States, where commingling of the races has taken place, the civilization of the land owes even more to the half-breed, *voyageur, courieur des bois*, etc., than to the Indian himself. (See CANADA.)

Throughout the continent—more especially, however, in parts of South America—devices for hunting and fishing and appliances in woodcraft, primitive agriculture, etc., were transferred to the European colonists during the period of settlement, and many of them are still in active use. Fish-poisoning by narcotics, the use of the blow-gun for killing birds and small animals without damaging the skin, methods of stalking beasts of the chase, certain traps and snares, etc., belong here. In connection with agriculture we have menhaden-manure, guano, etc., the planting of corn and beans or pumpkins together, the burning over of land before tillage, etc. But it is upon the food-supply of the world that the American Indian has exerted the greatest influence. Potatoes (common and sweet, both), maize, and the tomato, now in use by all the civilized world, were first cultivated by him and taken over by the whites after the discovery. Cacao, vanilla, jalap, the kidney bean, several varieties of squash and pumpkin, manioc, Jerusalem artichoke, coca, agave, quinoa, persimmon, and perhaps also the peanut, came to us from the Indians. Maple-sugar and maple-syrup, pemmican, jerked beef, etc., are from a like source. Tobacco, the great narcotic, was one of the first gifts of America to the Old World. Of drinks the American Indian has given us Paraguayan *mate*, "Labrador tea," and several other like concoctions, chocolate, Mexican *pulque*, and a considerable number of other intoxicating beverages from South America.

INDIANS

Many medicines and medicinal plants were made known to the whites by the Indians, and in the era of settlement and colonization the "Indian doctor" (male and female) was not unimportant,— New England, for example, had its "Joe Pye," after whom the "Joe Pye weed" (*Eupatorium purpureum*) is named. The Californian Indians have furnished perhaps the three most important contributions of recent years to the American pharmacopœia. South America, besides numerous locally known remedies, etc., has furnished the world-famous *quinine*, and *specacuanha*, while the drugs *cocaine* and *curari* must ultimately be credited to the aborigines of America. Many dye-stuffs and dye-woods were first given to the civilized world by the Indians, both for domestic use and for employment in the larger world of aesthetic manufacture. These dyes range from the poke of northeast North America for dyeing basketry to the famous *roucou* or *anotto* of Venezuela, used, among other purposes, for staining cheese. Pottery and other household utensils of Indian manufacture are used throughout Spanish America. The hammock of the Arawak Indians belongs now to all civilized peoples. All that India rubber means, civilization owes to the Indian. Both in small things and in great the American aborigines, through their gifts to the white race, will long be remembered, even if, as some authorities (upon imperfect evidence) believe, they are rapidly passing away. On this point one may cite the remark of Deniker that Humboldt in 1825 estimated the total population of America at 13,000,000 whites, 6,000,000 half-breeds, 6,000,000 negroes, and 9,000,000 Indians, while a computation made in 1895 reckoned 80,000,000 whites, 37,000,000 half-breeds, 10,000,000 negroes and 10,000,000 Indians.

There might be mentioned here also the "Chinook Jargon" of the Columbia River region, the "Ligoa Geral" of Brazil, and the minor jargons and trade languages of other sections of the continent, which prove how the Indian has compelled the white man, more or less, to use his language in some form or other for the purposes of friendly or commercial intercourse.

Antiquity of Man in America.—The question of the antiquity of the American Indian culture is difficult to settle satisfactorily. Time must be allowed for the divergence of the original stock into the numerous (more numerous in pre-Columbian eras) tribes and peoples inhabiting America at the time of its discovery,—time for the production of the Eskimo and the Iroquois, the Carib and the Patagonian. Time, again, must be allowed for the development of the Aztec from the primitive Shoshonean, the Mayan from the rude stock of that people, the Chibchan from the savage Bolivian, the Peruvian from the ancient barbarian of equatorial America. Then the civilizations of Mexico, Central America, and South America as such probably took ages to rise and flourish. Town and village life, with all its social and religious implications, the differing architectural monuments of the various centres of American civilization, etc., did not spring up in a day, any more than did the culture of mediæval Europe. The domestication of the dog, the llama, etc., the change of maize, tobacco, the squash, the tomato, the potato, the pineapple, etc., from wild to cultivated plants, require a long lapse of time. Moreover, it is now known

that American Indian languages do not now change and have not in the past changed at the fast rate once assigned to them by philologists. So, while one may not believe that America was the original habitat of the human race, he may be certain that very many millenniums have elapsed since the "Red Man" began his career as the autochthon of the New World. There seems every reason to believe that at the close of the Glacial Age man had spread over a considerable portion of both North and South America, and was contemporary with European man of an early epoch. To calculate man's residence in the American environment by years is impossible on present evidence. Dr. Stoll assures us that the linguistic phenomena met with in the Mayan dialects alone require thousands of years for their evolution, and some of the results deduced from the Mayan hieroglyphs by certain investigators imply the existence of civilization of the Central American order for very many millenniums. Perhaps it is fair to say that man has been in America at least 25,000 years and not more than 200,000, and that the civilizations of Mexico, Central America, and South America were probably as long-lived as those of Rome, Greece, etc. They were also in many respects just as typical of human attempt and achievement, for the American Indian was a man as we are men.

The 'Publications of the Bureau of American Ethnology,' embracing original monographs by eminent specialists, are a lasting monument to the founder of the Bureau, the late Maj. J. W. Powell, to whom all students of the aborigines of the New World owe a debt of deepest gratitude. Among workers not connected with the Bureau, the death of D. G. Brinton in 1899 removed perhaps the most gifted and representative Americanist.

ALEXANDER F. CHAMBERLAIN,
Clark University, Worcester, Mass.

Indicator, in steam engineering an instrument invented by James Watt, to record, graphically and automatically, the pressure in an engine cylinder at every point of the stroke. By means of the diagram that the indicator

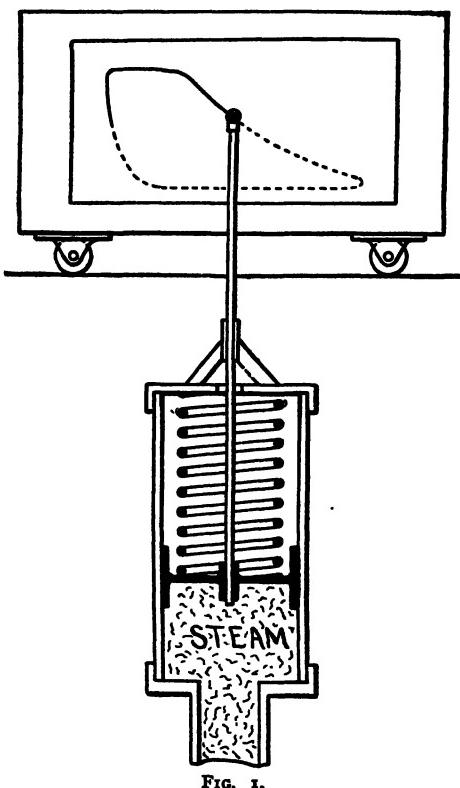

FIG. 1.

draws, it is possible to determine whether the valves of the engine are working correctly or not, and it is also possible to estimate the horsepower that the engine is developing, with con-

siderable accuracy. Commercially, the steam-engine indicator may be had in many forms; but all are based on the same fundamental principle, which will be understood by reference to the diagram presented in Fig. 1. The paper upon which the indicator diagram is to be drawn is here supposed to be secured, flat, to a carriage which travels back and forth upon a track; the motion of the carriage corresponding precisely

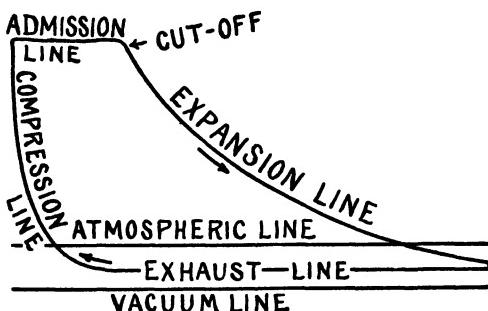

FIG. 2.

to the motion of the piston of the engine. In practice it would be inconvenient to have the carriage travel a distance equal to the whole stroke of the engine, and hence some form of reducing motion is used, so that the motion of the carriage may follow the motion of the engine piston accurately, but with materially reduced velocity. The indicator diagram is drawn by means of a pencil-point carried on the piston rod of a small steam cylinder which is situated below the carriage, and which opens freely into the cylinder of the engine from which the diagram is to be taken. The piston of the indicator is pressed downward by means of a spring whose strength is accurately known, so that the increase of pressure corresponding to a rise of one inch in the position of the pencil-point is known. When the indicator is in operation, the pencil rises and falls proportionately to the pressure of the steam in the engine cylinder, and the carriage, with its attached paper, travels back and forth, horizontally, at the same time, keeping pace precisely with the motion of the piston of the engine. Under these circumstances the pencil-point traces a diagram somewhat like that shown in the illustration. In practice, the paper upon which the diagram is drawn is usually wrapped about a cylindrical drum, which rotates back and forth as the instrument works, following the motion of the engine piston just as the carriage here shown is supposed to do. In Fig. 2 an enlarged view of an indicator card (or diagram) is given, together with the technical names of some of its more important parts. The arrows show the direction in which the pencil travels as the diagram is drawn. The "admission line" is the part that is drawn while the engine is in full communication with the boiler, and drawing steam from it. The angle marked "cut-off" corresponds to the moment at which the steam supply is cut off, and the expansion of the steam begins. The "expansion line" is drawn during the expansion of the steam, and on the return stroke, after the exhaust valve has opened, the "exhaust line" is drawn. When the exhaust valve has closed again, the steam remaining in the engine cylin-

INDICTMENT—INDIGO

der is compressed until the end of the stroke, the indicator meanwhile drawing the "compression line." The "atmospheric line" is the straight, horizontal line drawn by the engine when the connection is broken between the engine cylinder and the indicator cylinder, and the latter is open freely to the air. The "vacuum line" is the line that would be drawn by the instrument under like circumstances, if a perfect vacuum could be maintained in the indicator cylinder. The "vacuum line," of course, must be drawn in by hand. It is parallel to the "atmospheric line," and at a distance below it corresponding to a pressure of about 14.7 pounds per square inch, on the scale to which the diagram is drawn. The diagram shown in Fig. 2 refers to a condensing engine. In a non-condensing engine, the exhaust line would not be lower than the atmospheric line, and would, in fact, be above it, if there were any sensible back-pressure in the engine during exhaust.

For detailed information concerning the indicator and its uses, consult: Pray, 'Twenty Years with the Indicator'; Peabody, 'The Steam Engine Indicator'; also, for less extended treatment, any good book on steam engineering.

Indictment, *in-dit'mēnt*, a formal charge made before a legal tribunal against an accused person. The essential requisites of a valid indictment are,—first, that the indictment be presented to some court having jurisdiction of the offense stated therein; second, that it appear to have been found by the grand jury of the proper county or district; third, that the indictment be found a true bill, and signed by the foreman of the grand jury; fourth, that it be framed with sufficient certainty; for this purpose the charge must contain a certain description of the crime or misdemeanor of which the defendant is accused, and a statement of the facts by which it is constituted, so as to identify the accusation; fifth, the indictment must be in the English language, but if any document in a foreign language, as a libel, be necessarily introduced, it should be set out in the original tongue, and then translated showing its application, 6 Term. 162. The formal requisites of an indictment are, first, that the venue, which at common law should always be laid in the county where the offense has been committed, although the charge be in the nature transitory, as a battery. The venue is stated in the margin thus: "City and County of —, to wit." Second, the presentment, which must be in the present tense, and is ordinarily expressed in the following formula: "the grand inquest of the State of —, inquiring for the city and county aforesaid, upon their oaths and affirmations present." Third, the name and addition of the defendant; but in case an error has been made in this respect, it is cured by the plea of the defendant. Fourth, the names of third persons, when they must be necessarily mentioned in the indictment, should be stated with certainty to a common intent, so as sufficiently to inform the defendant who are his accusers. When, however, the names of third persons cannot be ascertained, it is sufficient in some cases, to state "a certain person or persons to the jurors aforesaid unknown." Fifth, the time when the offense was committed should, in general, be stated to be on a specific year and

day. In some offenses, as in perjury, the day must be precisely stated, but although it is necessary that a day certain should be laid in the indictment, yet in general the prosecutor may give evidence of an offense committed on any other day previous to the finding of the indictment. Sixth, the offense shall be properly described. This is done by stating the substantial circumstances necessary to show the nature of the crime, and next the formal allegations and terms of art required. As to the substantial circumstances: the whole of the facts of the case necessary to make it appear judicially to the court that the indictors have gone upon sufficient premises, should be set forth; but there should be no unnecessary matter, nor anything which on its face makes the indictment repugnant, inconsistent, or absurd.

According to the rules of pleading in criminal actions at common law there are certain terms of art used, so appropriated by the law to express the precise idea which it entertains of the offense, that no other terms, however synonymous they may seem, are capable of filling the same office; such, for example, as traitorously in treason; feloniously in felony; burglariously in burglary; maim in mayhem, etc. In New York, and in nearly all of the States which have adopted the code system, the common law rules of pleading in criminal actions have either been greatly relaxed or entirely abolished. Many of the statutes of the subject are similar to the New York statute, Code Crim. Pro. § 273, which in substance provides that all common law rules of pleading are abolished, and the forms of pleading prescribed by the code shall be substituted, and § 275 of the same code provides that all an indictment must contain is, the title of the section, specifying the name of the court to which the indictment is presented, and the names of the parties, and a plain and concise statement of the act constituting the crime, without unnecessary repetition. It is also provided in § 283 of the New York Code Crim. Pro. that words used in a statute to define a crime need not be strictly pursued in the indictment; but other words conveying the same meaning may be used.

Indigestion. See DYSPEPSIA.

Indigo, the name of a genus of plants, and of the blue coloring matter obtained from them. The indigo plants are tall herbs of the pea family, forming the genus *Indigofera*, of which there are several color-yielding species in various warm parts of the world. The one yielding the indigo of commerce, and formerly extensively cultivated, is *I. tinctorium*, which is native to India, grows five feet high, and has bipinnate leaves. The coloring matter most abounds in the leaves, and especially as the time of flowering occurs, and that is the time when the crop is gathered by cutting down the plant, and making immediate use of the green stems or foliage, or by drying them for subsequent treatment. This coloring matter is a chemical substance called *indican*, the glucoside of indoxyl, which is converted by oxidation into indigo. Until the discovery of the sea-route to India the only blue vegetable dye available in Europe was that derived from the woad (*q.v.*), which was limited and costly; this dye-substance was therefore regarded as one

INDIGO-BIRD — INDO-CHINA

of the most valuable of new commodities and a large capital was soon embarked in its cultivation in India, Ceylon, China, and other regions, where a profitable industry continued until after the middle of the 19th century. The indigo was obtained by macerating the leaves and stems in vats for several hours. Fermentation arises and the water becomes clear yellow. It is then run off into a lower basin, where it is subjected to incessant agitation and gradually turns green, whereupon the indigo begins to form in flakes and settle. The residuum is then thoroughly boiled, filtered through linen, molded into small cakes and dried. The best quality comes from Bengal and eastern India. Indigo plantations were made with more or less success in Brazil, Central America, and Mexico; and one of the foremost inducements held out to settlers in the southern colonies, from Maryland to Louisiana, was the probability of its successful cultivation there. The experiments never yielded results of much importance, partly because crops of tobacco, cotton, and food-stuffs were more profitable. Since the discovery of cheap methods of forming blue dyes from coal-tar the cultivation of indigo has declined greatly, but still supplies a steady demand from cloth-dyers who wish an imperishable blue of certain tints.

The wild indigo of the United States is any of several species of a closely related genus *Baptisia*, which flourishes especially in the Southern States. The best known is the yellow-flowered false indigo (*B. tinctoria*), or indigo brown, from which country people obtain a blue dye, and a domestic medicine.

Indigo Dyeing.—Before it can be employed in dyeing, the indigo must be brought into solution; and as indigo itself is insoluble, it must be first transformed into a soluble substance, so that it can penetrate the pores of the cloth, where it is subsequently again restored to the form of indigo. To bring the indigo into solution, it is ground up to a soft paste with water, after which it is thrown into vats along with ferrous sulphate, slacked lime, and water. The ferrous sulphate reacts with the lime to form calcium sulphate and ferrous oxid, the latter being immediately oxidized at the expense of part of the oxygen of the indigo, which in its turn is reduced to a substance called indigo-white. This dissolves in the presence of excess of lime, and the fabric to be dyed is dipped into the vat after the liquid in it is clear. On removing the fabric the indigo-white which has penetrated its pores is reoxidized by the air to indigo blue; and by repeating this treatment a shade of blue of any desired depth may be obtained. The dyed fabric is finally passed through dilute acid to remove any adhering lime or ferric oxid. Indigo appears to exist in the plant in the form of a glucoside known as "indican," which has the formula $C_{16}H_{10}N_2O_8$, and to be developed from this glucoside in the course of the fermentation by the action of a special bacillus, which closely resembles the bacillus of pneumonia. Indigo is now made artificially, the total production of synthetic indigo being probably about one fourth of the world's consumption. Although artificial indigo-blue appears to have the same chemical formula ($C_{16}H_{10}N_2O_8$) as the natural product, and to be identical with it in every way, it is more

expensive than the natural product at the present time. If it could be made more cheaply, it would work as great a revolution in dyeing as did the introduction of alizarin in the place of madder. (See COAL TAR COLORS, and the references there given.)

Indigo-bird, a numerous and beautiful North American finch (*Passerina cyanea*), the male of which is dark greenish blue, while the female is grayish brown. They are migratory, but in summer spread over most of the United States, placing their neat nest and unspotted bluish eggs in garden bushes as well as in wild thickets. The male has one of the brightest and most persistent songs of any American bird; and he is easily habituated to captivity.

Indigo-snake. The gopher-snake (q.v.).

In'direct Damages, claims for damages not directly inflicted by the illegal act complained of, but by other causes themselves due to that act. The great historical case is that of the United States claim for many hundreds of millions of dollars' worth of loss, resulting from Great Britain's bad faith or carelessness in letting the Alabama (q.v., and ALABAMA CLAIMS) escape from her ports to prey on our commerce. It was alleged that aside from the actual loss to our shipping and cargoes, we had been damaged to a far greater extent by the resultant effects, chiefly of three sorts: (1) The prolongation of the Civil War due to the encouragement given to the South and the straitening of the North. (2) The destruction of commercial lines and relations, which took long to recover after the War. (3) The raising of the rates of marine insurance. As these claims exceeded the cost of a war plus the indemnity we should have exacted if victorious, Great Britain refused to consider them; and the commission threw them out altogether as contrary to international law.

In'dium, the name given to a metal discovered by spectroscopic analysis in 1863. The zinc-blende of Freiburg was found by Reich and Richter, after a process of purification, to yield a substance the spectrum of which was different from all known spectra. They hence inferred the existence of a new element. This element has been isolated, but only in small quantities. It is of a silver white color, soft, and marks paper like lead; its specific gravity is 7.421 at 16.8° . The lead indium is related to cadmium and zinc, both of which occur associated with it in nature. The spectrum of indium exhibits two characteristic lines, one violet α and another blue line β ; besides these two fainter blue lines are visible if the burner in which the metal is volatilized be fed with hydrogen instead of coal gas.

Individ'u'alism is the name often applied to social systems founded on principles opposed to the essential principle of socialism, or to that theory of society which is opposed to state interference in industrial and economic and other relations. In its extreme form it is identical with one phase of anarchism. The word is also applied to social theories involving other and deeper views of individual rights than the mere non-interference referred to above.

Indo-China, the southeastern peninsula of Asia, formerly known as Farther India, including

INDO-EUROPEANS—INDUCTION

Anam, Burma, Cambodia, Cochin-China, French Indo-China, Tongking (qq.v.), and other districts.

Indo-European's, the Aryan race (q.v.). For accounts of the Indo-European languages see ARYAN; INDO-GERMANIC LANGUAGES.

Indo-Germanic Languages, the languages which are ancient and modern varieties of one primeval form of speech, anciently spoken in Central Asia. These languages are sometimes called the Indo-Celtic languages, the Japhetic languages, or more commonly, the Aryan languages. There are three forms of human speech, the monosyllabic, or isolating languages, such as the Chinese, whose words are unchangeable roots, each of which stands separately and is modified by the juxtaposition of other monosyllabic roots; the agglutinating languages, such as the South African, the Japanese, and the American Indian, in which, instead of being isolated, the roots are placed in close association, so as to agglutinate or agglomerate into one word. Some Eskimo words are as long as the longest compound epithet of Aristophanes. The third group are the inflectional languages. The Indo-Germanic languages are inflectional. In these the roots of all words are not necessarily modified, but they may be modified, in order to express certain relations, and the roots are also added to by suffixes and prefixes. The Indo-Germanic languages do not extend over so wide an area as the monosyllabic languages, but are spoken by the most civilized and intellectual peoples of the world. The Indic branches are the ancient Hindu languages, the principal of which is Sanskrit, and the modern Hindu languages. The Iranic or Persian branch includes, Zend, Old Persian, Armenian, Parsee, modern Persian and the dialect spoken by the mountaineers to the northwest of India. The great Hellenic branch was spoken anciently by the inhabitants of Greece, of the west coast of Asia Minor, of the islands of the Aegean, as well as of the south and southwestern coasts of Italy. It is spoken in a modified form in Greece and the Greek islands of to-day. Parallel to the Hellenic is the Italic branch, which includes the primitive Italic languages, Oscan, Etruscan, Umbrian, and Latin, as well as the classic Latin of Virgil and Cicero, which settled into the Italian of Dante and, on being extended over western Europe, grew through many modifications into French, Provençal, Italian, Spanish, Portuguese and Roumanian. Distinct from this branch was the Celtic, which survives to-day in the Welsh and Gaelic dialects. The Teutonic tongues include the Gothic of Ulfilas (4th century A.D.) the Norse languages, the Low German and the High German group. The Slavonic languages are spoken in Russia and Poland and include the Lithuanian and the Old Prussian. There are several other Indo-Germanic tongues and dialects which philologists have not been able to classify; such are the Etruscan in Europe and certain languages of Asia Minor. Compare: Schleicher, 'Compendium der vergleichenden Grammatik der Indo-Germanischen Sprachen' (1871); Corrsen, 'Ueber Aussprache, Vocalismus, und Betonung der lateinischen Sprache'; and most important Brugmann and Delbrück, 'Grundriss der vergleichenden Grammatik der Indo-Germanischen Sprachen' (1897 *et seq.*).

Induction. It is a familiar fact that an electrified (or magnetized) body causes electrical (or magnetic) disturbances in other bodies in its vicinity, when it is not in direct and visible connection with them, and the process by which these disturbances take place is called "induction." The ultimate mechanism of induction is still somewhat obscure, but something has been learned of its general nature. In the early days of physical science it was believed that bodies can act upon one another even across spaces that are absolutely void, and at the present time it is sometimes convenient to assume them to act in this manner, in forming mathematical equations for the treatment of physical problems. It is no longer believed, however, that this is what actually happens in nature; the phenomena of electric and magnetic induction being now attributed to motions or stresses in the ether which transmits light. (See ETHER.) Newton was of the opinion that induction is an ether-phenomenon, and in the first half of the 19th century Faraday may be said to have established the ether hypothesis upon a substantial experimental foundation. In later years Maxwell developed Faraday's conceptions mathematically, and added much more evidence that was partly theoretical and partly experimental; so that at the present time there are few or no physicists who doubt that induction is a manifestation of some form of activity in the light-bearing ether. Opinion is still divided, however, as to the precise nature of this activity. In fact, we cannot hope to gain any very precise information on this point until much more is known about the constitution of the ether itself.

The charging of a condenser is a phenomenon in electrostatic induction. If the condenser consists of two parallel plates (for example), of a given size and set at a constant distance from each other, and we charge it to a given potential, the quantity of electricity that must be put into it in order to charge it in this manner depends to a considerable extent upon the nature of the dielectric (or insulating material) which separates the plates. If the charge that is required when air is the dielectric is taken as unity, then with plate glass as a dielectric the charge will have to be 8.45 (according to Hopkinson), in order to bring the potential of the condenser up to the same value as before. If the space between the plates is filled with common turpentine, a charge 2.23 times as great as that required with air as the dielectric must be communicated to the condenser. It is evident, from these facts, and from others of the same nature, that electric induction depends, to a large extent at any rate, upon the nature of the medium which separates an electrified body from the other bodies upon which the inductive influence is felt. The constants that are given above are known as the "specific inductive capacities" of the dielectrics to which they refer.

Electrodynamic induction is the basis of practically all of the electrical machinery that has been found serviceable to man. The fundamental fact of electrodynamic induction may be stated as follows: If a closed electrical circuit, such as might be formed by joining the two ends of a copper wire, is placed in a magnetic field, then no current will be produced so long as the circuit is everywhere stationary, and the strength of the magnetic field remains every-

INDUCTION BALANCE

where invariable. If the intensity of the magnetic field is increased, a current of electricity will flow around the circuit while the intensity of the magnetism is changing, the intensity of the current being proportional to the rapidity with which the intensity of the magnetism varies. As soon as the magnetism again becomes constant, the current in the circuit ceases. If the intensity of the magnetic field be diminished instead of increased, a current will also be produced in the closed circuit, but it will be opposite in direction to that produced by increasing the magnetic field. Currents produced in this manner are called "induced currents." Instead of varying the magnetic field while the circuit is fixed in position, we may move the circuit about in the magnetic field. If the magnetic field is everywhere uniform in all respects, and the circuit is moved so as to always remain parallel to itself, then no induced current will be produced; but if the circuit is moved from a region where the magnetism is strong to one where it is weak, or *vice versa*, a current will be induced in the circuit, just as if the circuit were kept stationary and the intensity of the magnetism varied. Induced currents are also produced when, instead of being translated from one region to another, the circuit is rotated in a magnetic field, in such a way that the number of lines of magnetic force passing through it is either increased or diminished. In the induction coil the intensity of the magnetic field is varied, while the circuit in which the induced current is to be produced is kept stationary. In dynamos, on the other hand, the magnetic field is maintained sensibly constant, while the circuit in which the induced current is to be produced is rotated or otherwise moved about.

A current moving in a closed circuit produces a magnetic field in the space above it, and this magnetic field, when it varies on account of the variation of the current that produces it, causes the production of induced currents in any closed circuit that may happen to be near. Let us conceive two closed circuits, A and B, to be situated near each other, and let there be a current produced by any means in the circuit A. So long as the current in A is constant, no current will be produced in B; but if the current in A is variable, an induced current will be observed in B, whose intensity depends upon the rate at which the current in A is varying, upon the resistance of the circuit B, and also upon a certain numerical factor, whose value depends upon the sizes and shapes of the two circuits, upon their positions with respect to each other, and upon the nature of the medium (air, oil, or whatever it may be) in which they are placed.

If a pair of circuits, A and B, are near each other, and A is carrying a constant current of intensity C_1 , while B is carrying a constant current of intensity C_2 , then the displacement of either circuit, relatively to the other, would cause induced currents to flow in both; and hence (in general) neither circuit can be moved without the energy of the system being affected. The difference between the energy of a pair of coils that are near together, and the energy of a similar pair of coils that are conveying identically the same currents but are infinitely remote from each other, is equal to MC_1C_2 , where M is a numerical factor whose value depends upon the sizes and shapes of the two circuits, upon their relative positions, and upon the medium

in which they are placed. The factor M is called the "coefficient of mutual induction" of the pair of circuits.

The various parts of a single circuit act upon one another inductively, just as separate circuits do; and a circuit that is wound upon a spool, or otherwise coiled so that its parts come near together, possesses greater energy than the same circuit would have, if it was not so coiled. This fact is expressed by saying that every circuit has a certain amount of "self-induction." The energy that a circuit possesses in virtue of its self-induction is proportional to the square of the current that it is carrying, and to a certain numerical constant called the "coefficient of self-induction," whose value depends upon the size and shape of the circuit, and upon the medium in which it is placed. Like the coefficient of mutual induction of a pair of circuits, the coefficient of self-induction of a single circuit can be computed, for certain simple cases, by methods given by Maxwell, in his "Treatise on Electricity and Magnetism"; but in the general case the computation is exceedingly difficult, and altogether impracticable; so that the values of these coefficients for given circuits are usually determined experimentally, except when a very rough estimate will serve.

The general subject of induction is essentially mathematical in its character, and cannot be properly explained nor understood without the use of the calculus. Consult Nipher, "Electricity and Magnetism"; Maxwell, "Treatise on Electricity and Magnetism." See also the articles ELECTRICITY and MAGNETISM, in this encyclopedia.

A. D. RISTEEN, PH.D.,
Editorial Staff, "Encyclopedia Americana."

Induction Balance, in physics, an apparatus designed for detecting the presence of fragments of metal, or for studying the electrical conductivity of metals. It consists essentially of four coils of fine wire, an electric battery, a circuit breaker, and a telephone. Let the coils be designated, respectively, by the letters A, B, C and D; A being similar to B in all respects, and C being likewise similar to D. Coils A and B are placed in circuit with the battery, and coils C and D are placed in circuit with the telephone. The coils are disposed in pairs, A being placed near C, and B near D. If the current through A and B is rapidly interrupted, an induced current will, in general, flow through C and D, at each make and break; its presence being indicated by the sounds that it produces in the telephone that is in circuit with C and D. It is possible, however, to dispose the coils and their connections so that the current that A induces in C shall be sensibly equal and opposite to that which B induces in D. When the balance is perfect, no sound will be heard in the telephone. If a piece of metal be now brought near the coil A, the intermittent current in A will induce currents in the mass of the piece of metal, and these, in turn, will act upon the coil C, producing induced currents in this coil which are not compensated by similar currents in D. The loss of balance will be at once indicated by the recurrence of sounds in the telephone; and in this way the metal fragment will betray its presence. The induction balance has been used successfully for locating bullets in the human body. When applied for this purpose to President Garfield, however, it failed to give any useful indications,—owing, it is said, to difficulties of

INDUCTION COIL—INDULGENCE

manipulation due to the presence of metal in the mattress upon which he lay. The instrument is so sensitive that if it is balanced with a genuine coin near one of the coils, and the genuine coin is then replaced by a counterfeit imitation, the telephone at once betrays the substitution. The intensity of the sounds produced in the telephone depends not only upon the size and position of the disturbing piece of metal, but also upon its specific electrical resistance; and hence the balance may be used to compare the specific resistances of metals.

Consult Hopkins, 'Experimental Science'; Thomson, 'Recent Researches in Electricity and Magnetism'; Bell, 'The Induction Balance,' in the American Journal of Science for 1883.

Induction Coil, an electrical instrument used for the production of high potentials, and depending for its action upon the fact that induced currents are generated in a circuit, when the strength of the magnetic field to which the circuit is exposed is varied. (See INDUCTION.) The essential features of the instrument are represented, diagrammatically, in the accompanying cut. A soft iron core is surrounded by two

encre that is used is something over 100 volts. (See WEHNELT INTERRUPTER.) The primary coil on the iron core is made of a few turns of relatively thick copper wire, its purpose being solely to effect the magnetisation of the core; but the secondary coil, in which the induced currents are generated, is made of fine wire, and in order to multiply the inductive effect as far as possible, the secondary is made of great length, often containing many miles of wire. In the celebrated Spottiswoode coil the secondary contained no less than 280 miles of wire. The primary coil, being wound directly upon a soft iron core, commonly has a very considerable amount of self-induction, so that when the circuit is broken by the interrupter the current does not suddenly cease, but continues to flow across the interval at the break for an appreciable fraction of a second, as is readily seen by the strong sparking that occurs at the moment of interruption. In order to reduce the sparking as far as possible, a condenser of suitable capacity is provided, so that when the break is made in the circuit, the "after-current" due to the self-induction of the primary can discharge into the condenser, instead of passing across the break in the circuit and causing a spark. The condenser causes the interruption of the current in the primary coil to be much more sudden, and it materially increases the potential that is developed in the secondary coil, since this is proportional to the rate of variation of the magnetism of the core, and is much greater when the magnetism falls off abruptly than when it persists for an appreciable fraction of a second after the break has been made.

The induction coil was brought into something like its present form by Ruhmkorff, and is frequently known, in consequence, by his name. Improvements in the winding of the secondary coil were introduced by Ritchie, of Boston, about 1857. Ritchie's most important improvement consisted in disposing the secondary wire in sections, which were so related to one another that the risk of internal disruptive discharge through the coil itself might be reduced to a minimum. Induction coils are very generally used in studying the discharge of electricity through gases, for exciting x-ray tubes, and for producing high potentials required in wireless telegraphy. Consult Bonney, 'Induction Coils'; Alsopp, 'Induction Coils and Coil-Making'; Wright, 'The Induction Coil in Practical Work.'

coils of wire, one outside of the other. The outer coil is the one in which the high tension induced currents are produced; it is called the "secondary coil," and is not in direct electrical connection with any other part of the instrument. The inner coil, which is called the primary coil, is wound close to the iron core, and is connected to a battery, so that when the current from the battery is flowing, the primary coil causes the iron core to become magnetised. As is explained in the article INDUCTION, no current is generated in the secondary coil, so long as the magnetism of the iron core remains constant; but whenever the magnetism of the core increases or diminishes, a current is produced in the secondary. A device called a "break" or "interrupter" is therefore provided, so that the magnetism of the iron core may be rapidly established and destroyed. The commonest form of interrupter is that indicated in the cut, which does not call for special explanation, since it is used in electric bells and other simple forms of electrical apparatus. The Wehnelt electrolytic interrupter is greatly in favor among physicists, however, and is now often used in connection with induction coils, especially when they are to be run with the commercial current used for incandescent lighting, where the potential differ-

ence that is used is something over 100 volts. (See WEHNELT INTERRUPTER.) The primary coil on the iron core is made of a few turns of relatively thick copper wire, its purpose being solely to effect the magnetisation of the core; but the secondary coil, in which the induced currents are generated, is made of fine wire, and in order to multiply the inductive effect as far as possible, the secondary is made of great length, often containing many miles of wire. In the celebrated Spottiswoode coil the secondary contained no less than 280 miles of wire. The primary coil, being wound directly upon a soft iron core, commonly has a very considerable amount of self-induction, so that when the circuit is broken by the interrupter the current does not suddenly cease, but continues to flow across the interval at the break for an appreciable fraction of a second, as is readily seen by the strong sparking that occurs at the moment of interruption. In order to reduce the sparking as far as possible, a condenser of suitable capacity is provided, so that when the break is made in the circuit, the "after-current" due to the self-induction of the primary can discharge into the condenser, instead of passing across the break in the circuit and causing a spark. The condenser causes the interruption of the current in the primary coil to be much more sudden, and it materially increases the potential that is developed in the secondary coil, since this is proportional to the rate of variation of the magnetism of the core, and is much greater when the magnetism falls off abruptly than when it persists for an appreciable fraction of a second after the break has been made.

The induction coil was brought into something like its present form by Ruhmkorff, and is frequently known, in consequence, by his name. Improvements in the winding of the secondary coil were introduced by Ritchie, of Boston, about 1857. Ritchie's most important improvement consisted in disposing the secondary wire in sections, which were so related to one another that the risk of internal disruptive discharge through the coil itself might be reduced to a minimum. Induction coils are very generally used in studying the discharge of electricity through gases, for exciting x-ray tubes, and for producing high potentials required in wireless telegraphy. Indulgence, a theological term which means in the Roman Catholic Church "a remission of the temporal punishment which is still due to sin after sacramental absolution." It does not mean a remission of the guilt of sin, nor of the eternal punishment of sin, nor does it mean permission to commit sin. Indulgences "may be given by the Pope throughout the Church; by primates, metropolitans, and bishops ruling a diocese, within the limits of their jurisdiction." The Council of Trent (1563) condemned those who deny that the Church has power to grant indulgences or who assert that indulgences are useless. This same Council lays down the principle (Sess. xx. cap. 9) that indulgences must be given everywhere gratis. The difficulties which arose in the 16th century over the so-called "sale of the indulgences" were

INDULGENCE—INDUSTRIAL CORPORATIONS

not caused by disbelief in the doctrine but by a revolt against the misuse and abuse of indulgences. See LUTHER; TETZEL. Consult: ‘Catechism of the Council of Trent’; O’Brien, ‘Advanced Catechism’; Darras, ‘Church History’; Bellarmine, ‘De indulg. et jubileo libri duo’; Wetzer and Welte, ‘Ablass.’

Indulgence, Declaration of, the proclamation issued in 1687 by James II. of England by which he sought to relieve his subjects from observing laws opposed to their consciences. As the persons then suffering most from the laws were Roman Catholics, and as the laws would leave them free to worship according to their consciences, the proclamation was opposed by many king’s subjects. Seven bishops of the Church of England refused to order their clergy to read the king’s proclamation. Charles II. issued two similar indulgences in 1662 and 1672, both of which were unpopular with the people outside the Roman Catholic Church. The dissenters in England and Scotland, who might be benefited by the proclamation, refused to share toleration with the Roman Catholics.

In'dus (Sanskrit, *Sindhu*), the chief stream of the northwest of India, and one of the great rivers of the world. It has a length of about 1,900 miles, and drains an area of more than 360,000 square miles. It rises in Tibet on the north of the Himalaya Mountains, nearly 100 miles northwest from the sources of the upper Brahmaputra (q.v.), on the north side of the mountain mass of Kailâs, 18,000 feet above sea-level. In the upper part of its course it takes a northwesterly direction along the northern foot of the main Himalayan range, enters the Kashmir territories, passes through Ladak, below the capital of which, Leh, it receives the Zanskar, farther on the Dras, after which it enters Baltistan. Here it receives, on the right, the Gilgit, from a glacier of the Karakoram, the largest tributary that joins it in the Himalayan regions, and takes the name of Indus or Sind. About 100 miles below this it takes a sudden bend toward the southwest, and after a course of about 180 miles more in this direction it leaves the loftier regions. At the British fortress of Attock in the Panjab — where it is crossed by a great railway bridge carrying the line to Peshawar — it is joined by the Kabul from Afghanistan, and here, 950 feet above the level of the sea, it is nearly 800 feet wide and from 30 to 60 feet deep according to the season. For the rest of its course (about 900 miles) it continues its southwesterly direction till it enters the Indian Ocean. At Kalabagh, 110 miles below Attock, it has a breadth of over 1,400 feet. Arriving in the low-lying country, its waters become charged with mud, and in the rainy season, and by the melting of the snow in the mountains, it overflows its banks. Near Mithankot it receives on the east the Panjnad, or united stream of the Five Rivers of the Panjab. Below the confluence it has a width of over 1,900 yards when the water is low. In Sind it gives off several extensive arms or canals, which are of great value for irrigation; and below Hyderabad it divides into a number of shifting mouths or estuaries, the most navigable of which is at present the Yatho mouth. The delta, formed by the enormous amount of alluvium brought down by the river, has a

coast-line of about 130 miles, and the point or head of it at Tatta is 70 miles from the sea. The tide rises to this distance. The Indus loses much water from passing through dry and desert regions, and much is also drawn off for irrigation; accordingly it brings down much less water to the sea than the Ganges. Vessels drawing more than seven feet of water cannot generally enter any of its mouths; but steamers of light draft ascend from Hyderabad to Multan. A railway ascends the valley of the Indus from the important port of Karachi to Peshawar.

Industrial Commission, a non-partisan body authorized by Congress on 18 June 1898, to investigate the subjects of “immigration, labor, agriculture, manufactures, and business” in the United States, with the utmost fairness to both capital and labor, and report to Congress with suggested legislation, as a basis not only for national law and administration, but for uniformity of State laws. It was empowered to administer oaths in order to obtain sworn testimony, and send for persons and papers, as well as (by a supplementary act) to purchase relevant literature up to \$1,500 a year. The members were to be five Senators appointed by its president, five Representatives appointed by the Speaker, and nine private gentlemen appointed by the President and Senate, fairly representing different industries and branches of national life. Originally appointed for two years, the term was extended to 15 Dec. 1901, and then to 15 Feb. 1902, the last report being dated the 10th. The actual work was done by the private members, who employed 27 experts on the various lines, and examined nearly 700 witnesses; making a report in 19 volumes, of the highest value from the unmatched thoroughness and authoritativeness of the view on every side of our industrial system brought out, and the competence of the witnesses, who represented all grades, from heads of trusts to presidents of colleges, and from lawyers to heads of trade unions, leaving no field untouched. The commission also digested a vast amount of facts from judicial decisions and official documents. The private commissioners were A. L. Harris, S. N. D. North (successor Albert H. Clarke), Ellison A. Smyth (successor D. A. Tompkins), J. M. Farquhar, E. D. Conger, T. W. Phillips, C. J. Harris, M. D. Ratchford (successor C. H. Litchman), J. L. Kennedy. The experts were on warehouse and grain inspection laws, immigration (two, statistics and labor questions), agriculture (four, distribution, labor, speculation, and taxation), labor organizations, prison labor (two), railroad labor, Asiatic labor, strikes, and arbitration, trusts, transportation (two), railroad legislation, taxation of corporations (two), domestic service, pure-food legislation, mining industries, mining labor legislation, tobacco industries, mechanical progress, besides advisory counsel and expert indexing.

Industrial Corporations in the United States, include the large number of trusts, or industrial combinations, formed between 1800 and 1903. As the individual or private business firm gradually gave way to the limited partnership, so the limited partnership in turn practically yielded to the general corporate form of doing business, especially in respect to

INDUSTRIAL EDUCATION — INERTIA

manufacturing which followed the general tendency of business toward consolidation. This was a natural result of the rapid growth of capital, which consolidated for its own benefit. In this development some of the earlier and larger trusts undoubtedly played a very prominent part, creating a precedent, setting an example, as it were, notably the Standard Oil trust and the Sugar trust, both of which have been in corporate form for some years. They were the pioneers in consolidation of manufacturing interests, but compared with the more recent United States Steel Corporation, with its capital of more than a billion dollars, they are but pygmies. The great majority of these combinations have capitalizations in excess of \$5,000,000 each, while only a very few are capitalized at less than \$1,000,000. Many of these manufacturing combinations practically control a very large proportion of the entire business of the country in their particular lines and are ever extending that control to other countries.

The most notable feature in the increase in the industrial growth of the United States from 1883 to 1903 is in the iron and steel industry, in which the production is nearly six times greater than it was at the beginning of that period. The total quantity of pig iron and steel produced in 1882 was 5,360,015 tons. In 1892 the quantity was 14,084,581 tons, and in 1902 it had increased to 31,255,595 tons. The increase in the production of pig iron in 1892 over 1882 was 98.99 per cent; and in 1902 over 1892 it was 49.18 per cent. The increase in the annual production of steel, however, was much greater in proportion. In 1892 it was 183.38 per cent greater than in 1882, and in 1902 it was 174.34 per cent greater than in 1892. Among the advantages of the corporate form over individual ownership which so largely tend to the advantage of consolidations of capital and the supplying of the demand for greater facilities for its employment in industrial fields is the fact that, while stockholders die, the corporation can

go on forever. The ownership of these corporations is divided among hundred of thousands of individual stockholders, who are liable only for the amount of their stock, and which can be transferred without affecting the corporation or its liability and without any trouble. The number of stockholders of four of the largest corporations, for instance — namely, the United States Steel Corporation, the American Sugar Refining Company, the Amalgamated Copper Company and the Standard Oil Company — number about 100,000 persons.

The census of 1900 gave the following statistics of industrial corporations (first table below) :

In 1902 these figures had materially increased, there being 213 industrial combinations or trusts with a capital of \$6,639,019,304, but even these figures are far from the estimates made in 1903 by Moody (Manual of Corporate Securities) who places the total capital at \$9,000,000,000, and who states that the railroad consolidations would increase this to \$15,000,000.

The United States Steel Corporation, the largest of the trusts, and its competition are marvelous examples of the "combination" plan of capital. The following are the figures for 1902 (see second table below) :

Industrial Education. See ART EDUCATION.
Inebri'ety. See ALCOHOLISM.

Iner'tia, a term introduced by Kepler to signify that property of matter in virtue of which it is "inert," so that when a body is at rest, or in a state of uniform motion in a straight line, it preserves its state of rest or of uniform rectilinear motion, unless some agency external to the body acts upon it in such a way as to modify that state. We gain our first conception of inertia by the attempts that we make to move bodies that are at rest, or to stop those that are in motion. Even if they are suspended freely, so that frictional forces are negligible, we find that their state of rest or motion cannot be

INFALLIBILITY — INFANCY

modified without the exercise of a certain amount of muscular force; and by abstracting our own personality in the case, we gradually come to the conception of inertia as a physical property inherent in all bodies. Inertia has been popularly described as a "passive resistance" to change of motion; but this expression is objectionable because it is entirely inaccurate. Freely suspended bodies (that is, bodies that are free from frictional forces,) cannot be said to "resist" forces that are applied to them. On the contrary, they yield instantly to the smallest force; but a small force, when exerted upon a given body, for a given length of time, does not produce as great a change of motion as would be produced by a large force acting upon the same body for the same length of time. The conception of inertia shades insensibly into that of "mass"; the mass of a given body being proportional (by definition) to the velocity that is communicated to the body by a force of standard intensity, acting upon it for a standard length of time. (See MASS; MATTER; MOLECULAR THEORY.)

Infallibility, exemption from the possibility of error. The word is used as applied to arguments, statements, reasoning, or the formation of judgments, and does not include impeccability, or exemption from the error of sin. The infallibility of the Church as believed by Roman Catholics means that "the Church can neither deceive nor be deceived in matters of faith and morals"; and she is limited to the definition of truths already contained in Scripture and tradition. The seat of infallibility rests in the Pope as successor of Saint Peter (Matt. xv. 18), and in the bishops in communion with the See of Rome, whether dispersed or united in a General Council (q.v.). In the acts of the Vatican Council, held in Rome in 1870, the following is the text defining the nature of the infallibility of the Pope: "The Roman Pontiff, when he speaks *ex cathedra*, that is to say, when in the exercise of his office of pastor and teacher of all Christians; he, in virtue of his supreme apostolic authority defines that a doctrine on faith and morals is to be held by the whole Church, by the assistance of God promised to him in the person of blessed Peter, has that infallibility with which it was the will of our Divine Redeemer that His Church should be furnished in defining a doctrine on faith or morals, and that therefore these definitions of the Roman Pontiff, of themselves and not through the consent of the Church, are irrefutable." The Greek Church, the Church of England, and the Protestant Episcopal Church which is its representative and in communion with it in the United States, believe that infallibility resides in the universal Church in accordance with Christ's promise of the Spirit that should guide His followers unto all truth. Consult: Allies, "See of Saint Peter"; Ballerine, "De Primatu"; "De Potestate Summ. Pontif."

In'famy and Infamous Crimes, in common law the first means disqualification from giving legal evidence as a result of having committed the second, the theory being that a person capable of such crimes is incapable of speaking the truth. Both in Great Britain and generally in the United States this disqualification has been abolished by statute, and previous convictions

for crime have been considered to affect a person's credibility without impairing his legal capacity to give evidence. Infamous crimes are strictly those which entailed infamous punishments. The fifth amendment to the Federal Constitution speaks of "capital or otherwise infamous crime" and we read in 2 Dane, Abridgement, 569, 570: "Punishments clearly infamous are death, gallows, pillory, branding, whipping, confinement to hard labor and cropping." Infamous punishments include imprisonment in State prison, or penitentiary with or without hard labor, and crimes which entail such punishments are undoubtedly to be considered infamous crimes, in the sense implied in the fifth amendment to the Constitution.

Infancy. The term infancy is used variously by different writers to include a shorter or longer period of the earliest stage of human existence. By most writers it is limited to the first 12 or 14 months, extending to the time when the baby begins to walk and to talk, and so is synonymous with a "babe in arms"; many medical authors would make it include the whole period of the first dentition, or up to about two and a half years. The characteristics of the period are utter helplessness, rapid growth of body, gradual development of muscular functions and great impressibility of the nervous system. In mankind this helplessness is more marked and the period of dependence is longer than in any other of the higher animals. It has been pointed out by John Fiske that the present elevation of man above other animals is due largely if not entirely to this lengthened period of plasticity,—to his prolonged immaturity. Man is born with only a few of the lowest vegetative capacities fully developed, such as digestion, respiration, and circulation; the muscular and nervous functions are latent and only gradually develop; while the higher functions of the mind go on evolving until the fifth decade of life. A long infancy or period of immaturity means a great capacity for development.

Birth and Heredity.—The infant comes into the world with a fixed sum total of vital force, along with certain hereditary tendencies in development toward health and, perhaps, toward disease. These hereditary tendencies are all modified by the physical, social, intellectual and moral status of the child's family and surroundings: in a word, they are vastly influenced by the child's environment. Heredity was formerly regarded as the most important factor in the child's life; but heredity is really only one of three great factors,—the others being the nutrition of the child, and his physical, intellectual and moral environment. During the plastic years of infancy, childhood and adolescence, a bad heredity can frequently be overcome by proper management: on the other hand, the capital of a good heredity can be squandered. Nature always tends toward the normal or healthy, so that there is always the possibility for a bad heredity to be obliterated if only the natural tendency is assisted. More then depends on the nutrition and environment of the infant than upon its heredity.

Nutrition: Breast-Feeding.—The best method of nourishing the infant is nature's way—to have it nursed by the mother. But for various

INFANCY

reasons this is often impossible. Modern life—and especially city life—has in some way rendered a large proportion of women incapable of producing breast milk for their offspring. And the number of these mothers who desire to nurse their infants but cannot is increasing each year. Again, in not a few instances, the infant does not thrive upon the breast-milk, even though it may be abundant. In both these classes of cases some form of artificial or substitute feeding is a necessity. Good wet nurses are so difficult to procure in the United States that artificial feeding is generally preferable unless the baby is premature or feeble and failing: then the services of a wet nurse may be needed to save the infant's life.

Artificial or Substitute Feeding.—The best available substitute for human milk is an adaptation of fresh, clean unadulterated cow's milk. The milk should be diluted and otherwise modified to suit the infant's feeble digestive powers, and it should be given preferably, without being scalded or sterilized. In summer, or when there is any doubt as to the freshness of the milk, the cleanliness of the dairy or the careful handling of the milk, "Pasteurization," or heating the food to a temperature of 155° F. is advisable. Details as to milk modification and Pasteurization can be found in any book on "Infant Feeding." Ready-made infant foods,—the canned or bottled proprietary foods—do not contain the right ingredients for properly nourishing the infant, and their prolonged exclusive use is nearly always followed by some form of malnutrition—especially scurvy and rickets. These proprietary foods contain large proportions of sugar or starch, and so make fat babies, but such infants are generally pale, have feeble powers of resistance, and are prone to succumb to disease of the lungs or of the digestive tract. When the prepared infant foods are used as additions to milk they are less objectionable, and may at times be of advantage.

Weight and Development.—The infant that has been properly nourished before birth and is born at full term weighs on the average about 7½ pounds—boys being somewhat heavier than girls.

During the first few days, while the nourishment from the mother is insufficient, the baby regularly loses from six to eight ounces; but it soon begins to gain, and if the nutrition is normal and the infant remains well, there will be a steady increase in weight throughout the first two years. The gain during the first year is more regular, however, as well as more rapid than that during the second year. During the first three months the increase in weight each week is about half a pound: from the third to the sixth month the weekly gain is somewhat less, from four to six ounces: from the sixth to the ninth month about four ounces, and after the ninth month a little more, usually a weekly increase in weight of from four to six or even eight ounces. By the end of the fifth month the baby that has been perfectly well and is being properly nourished should have doubled its birth-weight and weigh about 15 pounds: at the end of the 15th month it should weigh three times its weight at birth. In many instances the baby will treble its original weight by the end of the first year; but 21 pounds may

be considered the average weight for the end of the 12th month. Infants that were very large at birth do not increase so rapidly; while small or premature babies are apt to make a gain that is greater in proportion to their original weight. "Hand-fed" or "bottle" babies should weigh on the average about the same as breast-fed babies,—provided that they have had no disturbance of their digestion; the food must, however, have been perfectly adapted to the infant, and this is often a very difficult problem.

Height and Other Measurements.—At birth the length of the average baby is about 20 inches; during the first six months there is an increase of four to six inches, and during the second six months from three to four inches more; by the end of the second year the height is 32½ inches, a growth of over a foot since birth. By the end of the third year the stature is one half of the adult height. The head grows very rapidly during infancy and early childhood. The circumference of the head at birth is from 13 to 14½ inches; by the end of the sixth month it is 16½ or 17 inches; at the end of the first year 18 inches, and at the end of the second year it is 19 inches. By seven or eight years the circumference of the head almost equals the adult size of 21 inches. This is visible evidence that during the first months and years of life the brain is increasing in volume more rapidly than any other organ in the body,—the head or brain-box expanding to conform to the enlarging brain. The soft spot or "fontanel" usually closes between the 15th and the 20th months. The chest is smaller than the head at birth (13 inches), but its circumference increases rapidly, so that at 18 months that of the chest and the head are equal. After this the chest grows steadily but gradually until puberty, when there is a very rapid increase for four or five years. Aside from the regular increase in weight and measurement, the healthy infant shows other signs of well-being. The baby's flesh is firm, and the skin is satiny and elastic: the color is pink, and the body and extremities are well rounded. Very fat babies are not necessarily stronger or healthier than those that weigh less: as has already been noted they are apt to be pale, flabby and of weak resistance to disease. The healthy baby is happy and playful when awake, and sleeps from 16 to 20 hours out of the 24,—longer the younger the baby. It is desirable that the growing child have a nap during the day up to the time when kindergarten work is begun; with nervous or poorly nourished children the practice should be continued until the seventh or eighth year.

Muscular and Mental Development.—These begin with the entrance of the infant into the world, but are slow in unfolding. At first the grosser movements performed by the muscles working over the larger joints, next more complex movements, and during later childhood and early adolescence the finer movements requiring nice adjustment and delicate co-ordination. Hence it is that occupations or accomplishments requiring great manual dexterity, such as violin or piano-playing, should be taken up early,—"before the hand gets stiff," as the phrase is. The first movements are those of the legs, arms,

INFANCY

and neck: they are not purposeful but merely reflex. By the sixth week the infant can hold up its head, when the back is supported, but very unsteadily until about three months old. At some time in the third or fourth month the infant makes its first voluntary movement, grasping at some object in the range of vision. Within a month or two later the baby can co-ordinate the muscles of the eyes, arm and hand sufficiently to take firm hold. Sitting alone is an accomplishment of the seventh or eighth month, and creeping also begins at about this time, if the baby is ever to creep at all. During the eighth or ninth month the baby begins to stand, having made the attempt for many weeks before; at ten or eleven months the infant can stand alone, and shortly after the twelfth month the first tottering steps are taken. It is some months before the baby is secure upon the feet, the maintenance of the equilibrium requiring nice control of many groups of muscles. Healthy infants differ greatly as to the time when they can walk alone, some walking at as early as ten months, while others may not walk until eighteen months. Very fat babies walk late but, in some instances, an excess of caution seems to be a factor. If a child is far behind in performing any of these muscular functions, a physician should be consulted so that careful examination may be made for signs of rickets or of disease of the brain or of the spinal cord.

Development of Special Senses.—For the first few days the newly-born infant avoids the light, and for many weeks cannot endure a direct bright light. Perception of light soon develops, the color first attracting attention being red. Clear perception of objects comes during the fifth month. Hearing is in abeyance for several days, a baby at birth being practically deaf; but after a week or ten days this function begins, and later hearing becomes very acute, the infant being able to recognize the mother's voice or a footstep at about three months. Loud sounds cause the baby actual pain, so severe are their impressions on the delicate auditory apparatus. The sense of touch (contact) is early developed, especially in the tongue and lips; but sensitiveness to pain is very dull during infancy. Heat and cold are recognized from an early period, the variation of a few degrees in the temperature of the food causing the baby to refuse it. Taste and smell also are present at birth, taste being very discriminating.

Development of Speech.—Speech is very closely related to the higher functions of the brain, and is therefore the last of the simple functions to develop. Usually a baby begins to say "Mamma" and "Papa," with clear knowledge of the meaning, toward the end of the first year. Next names of objects and persons are learned and soon two words are put together. Then verbs are used, and about the end of the second year little sentences are made. Pronouns are regularly the last of all the parts of speech to be used. During the third year speech develops very rapidly, the baby bringing out some new term or expression almost daily. There are great variations in the time when children begin to talk; and for this there are many reasons. Girls generally talk earlier than

boys by two or three months: babies that associate in the nursery with other children talk earlier than only children. If, however, a young child reaches the age of two years without attempting to talk, mental backwardness or organic brain disease is apt to be the cause. Tongue-tie is seldom the cause of backwardness in talking, although it does produce imperfect articulation.

Dentition—Teething.—The first teeth appear about the sixth or seventh month, but a perfectly healthy baby may have no teeth until 10 or 11 months old, or on the other hand may cut the first tooth at four months. The regular order is as follows: lower central incisors, upper central incisors, upper lateral incisors, lower lateral incisors—each pair coming at intervals of three to six weeks: at about the fourteenth month the front double teeth (anterior molars) appear in the two jaws, and four or five months later the canines, known popularly as the "eye and stomach teeth." Finally, the last four molars appear sometime between the twenty-fourth and the thirtieth month, and these complete the twenty teeth of the first dentition. Teething babies are apt to be fretful, they have a reduced resistance against disease, and they are prone to slight disturbances of digestion. To attribute most of the ills of infancy to the process of teething is a great mistake; usually some other and better cause for the disturbance can be found if the baby is carefully examined. During the time when the successive pairs of teeth are coming through the gums, the usual food should be largely diluted, so as to prevent any serious indigestion.

Fever.—Sudden high temperature is readily produced in young children by slight causes, inasmuch as the heat-regulating centre in the brain is but poorly developed. Again, the temperature in disease is erratic, and is apt to be higher than in adults suffering from the same ailment. Only persistent high temperature need cause anxiety.

Convulsions.—A characteristic of infancy is the easy excitability of the motor side of the nervous system. Hence convulsions or spasms are much more frequent and less serious than in adults. The immediate cause of the motor explosion may be an overloaded stomach, fright or mental excitement, or the fever of an oncoming disease. Severe earache, intestinal worms or a paroxysm of whooping cough may also serve as an exciting cause. Underlying or predisposing causes are a nervous heredity, malnutrition, or rickets; or there may be organic disease of the brain or the kidneys. The spasm usually begins with a turning of the eyes to one side and twitchings or grimaces of the face: there may be frothing at the mouth; then the arms and legs are rapidly contracted and relaxed; later the body stiffens out, the breathing becomes noisy and labored, the face,—especially the lips—becomes livid. Shortly afterward the body relaxes, the breathing becomes easy, and spasm ceases for the time being—having lasted anywhere from five to thirty minutes. Until the physician arrives certain simple measures are of value. The infant should be undressed, wholly or partially, and put into a warm bath (not warmer than 105° F.) to which a handful of mustard flour

INFANT—INFANTA

has been added, and the baby should be rubbed all over while in the tub for about five minutes. Then remove from the bath and lay between blankets, putting a warm bottle at the feet and an ice cap or cold compress on the head. If the baby can swallow, a full dose of castor oil should be given. Most convulsions are due to the presence of decomposing food-remains in the alimentary tract, and the spasms usually cease when the stomach and bowels have been thoroughly evacuated.

Clinic, Columbia University.*

Infant, in law. By the common law persons come to majority at the age of 21 years, until which time they are called in law *infants*, but by common usage in the United States the word *minor* prevails. Infants cannot, in general, bind themselves by contracts, as they are supposed not to have sufficient discretion and ability for this purpose. But this is their privilege, and their contracts are accordingly held in general not to be void, but only voidable at their election; and they may elect to avoid their contracts during their minority, except such as they may have entered into for necessaries suited to their condition in life, but they cannot confirm them so as to be bound by them until their majority. Infants may possess property, but it must be under the management and control of a guardian. They have not the right of citizens as to voting, and discharging other political functions. But in regard to crimes and punishments, and trespasses and private wrongs, their conduct is regulated by the same laws as that of the other members of the community, in case of their being of sufficient age and discretion to understand their duties and obligations. And for this purpose no general limit can be assigned, as some children are much more intelligent than others of the same age; and it will again depend, in some degree, upon the nature of the offense committed, or the wrong done, whether a child of any given age can be considered legally guilty of it, since some offenses and wrongs can be more easily understood to be such than others. The law, in general, has a tender regard to youth, and does not permit them to be convicted and punished for offenses and trespasses unless it appears clearly that they have sufficient knowledge and discretion to distinguish them to be such. There are exceptions to the incapacities of minors as to contracting, and these exceptions are made for their benefit. Thus an infant not sufficiently furnished with necessary clothes, food, or instruction, by his parent or guardian, and not being under the immediate superintendence of the parent or guardian, may make a valid contract, in respect to those subjects, and such contract may be enforced against him. Infants require the consent of parents or guardians to marry. The jurisdiction in respect to infants is generally vested in either probate or orphans' courts. These courts appoint guardians to take charge of the property of infants, and, in case of the decease of the father, to take charge of their persons; but during the life of the father he has the guardianship and control of the persons of his children until they are 21 years of age.

Blackstone thus defines infant: "Infants have various privileges, and various disabilities; but their very disabilities are privileges, in order to secure them from hurting themselves by their own improvident acts. An infant cannot be sued but under the protection, and joining the name of his guardian, for he is to defend him against all attacks as well by law as otherwise; but he may sue either by his guardian, or by his procurator amy, or alone for wages in the county courts. In criminal cases an infant of the age of 14 years may be capitally punished, but under the age of 7 he cannot. The period between 7 and 14 is subject to much uncertainty; for the infant shall, generally speaking, be judged *prima facie* innocent; yet if he was *doli capax*, and could discern between good and evil at the time of the offense committed, he may be convicted, and undergo judgment and execution of death, though he has not attained to years of puberty or discretion."

Infant Jesus, Daughters of the Congregation of the, is an order in the Roman Catholic Church. It owes its origin to Anna Maroni, a native of Lucca, who having come to Rome entirely destitute, succeeded by her industry in securing a competency. In more advanced years, her charitable feelings prompted her to establish an institution where poor girls should be instructed in such work as would enable them to earn a livelihood. The clergy approved of her plan, and afforded her much assistance, and it was finally established as a regular institution, and in 1673 Pope Clement X. acknowledged the existence of the society, gave it by-laws, and endowed it with sundry privileges, under the appellation of "Daughters of the Infant Jesus." The number of the "Daughters" allotted to each convent was fixed at 33, in commemoration of the number of years Jesus lived upon earth. The novitiate lasts three years; the sisters make vows of poverty, chastity and obedience. Such as may wish to leave the convent are allowed to do so before taking the vows, but, in that case, they are to leave to the convent all they brought to it at their admission. Prayers and fasts are strictly enforced. The regular habit of the order consists of a wide, dark brown dress, and a white hood.

Infanta, ēn-fāntā, Philippines, a former Spanish commandancia of the island of Luzon, consisting of a narrow strip of territory on the Pacific coast with Nueva Ecija on the north and Tayabas on the south. In 1902 it was made a sub-province of Tayabas, "the inhabitants to enjoy the same rights and privileges as if the said territory had been originally incorporated in the province of Tayabas." The surface is very rough and mountainous and the construction of roads impossible except at heavy cost; several trails lead over the mountains to the central provinces. The forests are valuable, among the trees most important to commerce is the balate, which produces the balate gum. The agricultural methods are most primitive; the chief crops are rice, cocoanut, chocolate and coffee; the most important industry is the manufacture of nipa wine; there was formerly a large manufacture of cocoanut oil in Infanta, but this industry was paralyzed by the hurricane of 1882. Pop. 10,800.

INFANTICIDE — INFANTRY

Infanticide, the murder of a child born alive, is a crime of frequent occurrence. The main cause of the crime is shame, induced by a dread of the social disgrace attaching to mothers of illegitimate children; though in many instances infanticide has been the result of violence produced by puerperal insanity. The morbid disposition to kill the newly born has also been observed in certain of the lower animals. The sanctity of human life, from its beginning to its close, is a maxim of modern civilization, and the law treats as a murderer whoever wilfully terminates it at any stage. According to the law of England every woman who employs means to procure criminal abortion is guilty of felony, and liable to penal servitude for life, or not less than three years; and severe penalties are inflicted on those who aid women to procure miscarriage. The concealment of birth is a misdemeanor, and may be punished with imprisonment for two years. In the United States, when a child's death is occasioned by an illegal act, such act is considered either murder or manslaughter according to the circumstances. The crime, however, is rarely punished, and in large cities many cases occur each year which are never reported to the authorities.

Infanticide was prevalent in Greece and Rome. In modern times many barbarous peoples are guilty of wholesale child-murder. Among some of the Pacific Islanders and aboriginal Australians there is a great destruction of infant life. The Hindus used to destroy female children without compunction. In China infanticide is said to be very common.

Infantry ("the juveniles," probably at first the knights' pages), foot soldiery, as distinguished at once from cavalry and artillery. In all ages this has naturally formed the numerical bulk of armies, but its tactical importance has varied greatly with circumstances. The name cannot be given to the mere unorganized fighters of barbarian *mélées*; it implies some organization, and at least the rudiments of tactics. The first large armies were the Egyptian and Assyrian, continued by the Persian: the social system was aristocratic, and the large plains ideal for the utility of cavalry; hence the infantry was rather an auxiliary, to complete a rout after the mounted lords and the chariots had broken the ranks, than the main fighting body. The first development of infantry as the chief reliance was naturally in the small Greek states, whose independence rested on their citizen soldiery, and whose rough territory made cavalry evolutions difficult. Cavalry was therefore used mainly to guard flanks and to skirmish; the Spartans for a long time would not use it at all. The infantry was divided into classes according to armor; hoplites (with heavy defensive armor, long spear and dagger), psiloi and peltasts (very little armor, light barbed javelins to throw), and gymnetes (sharpshooters, light-armored and with slings or bows). The battle formation was the famous phalanx, whose one basic principle was the value of mass and momentum, and which was irresistible either for attack or defense against barbarians who lacked firmness in the ranks. It was commonly a rectangular block eight ranks deep, so that only the first two or three could use their

spears at the same time, the rear ranks serving only for instant reinforcement and for impact; the men were from 18 inches to 6 feet apart, according to conditions of defense or attack; the phalanx had usually 2,000 to 4,000 men, but sometimes as high as 10,000 or more. Sometimes the formation was the triangular wedge. The first great improvement was by Epaminondas, who made the ranks 50 deep, and by the enormous impact crushed the Spartan phalanx at Leuctra. This was the Napoleonic principle of concentration at the critical point, most of the Spartan army being allies with no heart in the fighting, and kept at bay by a few skirmishers. Nevertheless, the step was backward except for immediate necessities, as it increased the main vice of the phalanx — its immobility, which made it break up dangerously on bad ground, and gave little power to change front or execute flanking movements. In later tactics the larger ones were subdivided into companies of 120 with a distance equal to the front, forming an approach to the legion; and the latter was copied also in the formation by lines, increasing rapidity of movement and flexibility on difficult ground, as well as power of extension and so of flanking. The Macedonian *sarissa* or long pike doubled the number of ranks which could thrust at once over each other's shoulders. But the whole system went down before the Roman legion, which essentially maintained its position till the Empire too went down. It consisted normally of 1,200 each of hastati (spearmen), principes (veterans), and velites (light troops), 600 pilani (veteran reserves), and 300 equites or cavalry. It was divided into three lines and 30 maniples or companies, and combined solidity with ease of maneuvering.

In the Middle Ages, till the general use of gunpowder, the feudal system insured the degradation of the infantry, as it depended on the fighting power of the knight, and consequently lavished all the care and expense on perfecting his armament. But even without this, the same result would have come, for without good field artillery, and with only bows and arrows at their best, the heavily armed man was invulnerable, as the Spanish conquests in the New World amply prove. Hence the logical result was the extension of defensive armor till some new missile force came in. But the cost of this was so great — a full suit of steel armor cost about \$2,000 — that only the richer even of the knights could afford them, no king could raise money to equip a standing army, and the aristocracy would combine to refuse him money for such a purpose; and the rank and file were scattered and slaughtered in face of a charge of a small number of mailed knights. The defeat of the French knights by the English bowmen was that of a disorderly and insubordinate mob, by a splendid archery which slew their horses and pierced the cheaper armor. But gunpowder at once changed the whole situation. A serf with a \$10 hackbut could stand out of reach and kill a knight with his costly armor; and a sovereign could collect and arm a great force of these and use them to put down his unruly vassals. Hence armored knights and horses began to decrease, and standing bodies of foot soldiery with firearms to increase. The change in battle array was correspondent: theretofore, even the ablest commanders had maintained the great depth of 10 ranks, traditional from classic times. Gustavus

INFECTION

Adolphus reduced this to six, deploying to three under fire; while Tilly and Wallenstein and the other imperial commanders kept to the old phalanx formation. Breitenfeld (1631) and Lutzen (1632) were won by this and Gustavus' light artillery. The introduction of the bayonet about 1650 led to a reduction to four ranks. But the greatest single improvement was due to Leopold of Dessau early in the 18th century: he instituted the chief reforms usually credited to Frederick the Great, and formed the armies with which Frederick won his victories. He reduced the ranks to three, making it possible for all to fire, trained them to maneuver with great precision, and wrote the drill-book which is still the basis of all European and American manuals. Frederick's infantry organization, in regiments of two or three battalions, each 500 to 600 strong, was copied by all the other nations; and the general principle of open order, made necessary from the destructiveness of artillery on close masses of men, and possible by the confidence in each other bred by civilization, is still retained. Broadly, the difference between ancient and modern infantry is that between mass and mobility.

For obvious reasons—cheapness of maintenance, universal availability of men untrained in horsemanship, ability to march and maneuver on all sorts of ground, less liability to be crippled by loss of the animals, etc.—all modern armies consist mainly of infantry; and the nominal horse troops are most often dragoons, or soldiers mounted merely for quickness of movement, but who fight on foot. The quantities of other arms, as cavalry, artillery, engineer corps, etc., are based on the infantry numbers. The proportions vary in different armies and in different functions of the same army, according to nature of service: more or less cavalry and artillery being used according to need of concentration, or action in dispersed bodies. Forces like the United States Western troops a generation ago, for instance, in small squads on detached duty, would have different proportions from a great Continental army in the midst of a campaign. While there is no one system of infantry tactics which can be universally applied, the same cause which has made the change just spoken of has thus far continued to act with steadily increasing force. Artillery continues to grow in power and in range; the danger-line grows ever farther from the enemy; it is nearly impossible, and would be murderously losing, to charge in close column across the 2,000 yards which is now the average range. The system adopted is called "extended order," which means a considerable space between the men, and small bodies acting separately in a charge; each making a rush for some cover not so far off that they will be blown in reaching it, or will be decimated in the attempt. A certain relation between companies and regiments is kept up, to avoid destruction in detail and enable combined action, but precise parade alignment is not attempted. This involves not only the mutual confidence of civilized men, but some of the independent judgment of those who have not had initiative crushed out of them by red tape: the greatest of modern tacticians and commanders have expressed a preference for intellectual quality over mere numbers, even in the rank and file. In the United States, the ex-

tended order was first introduced in the Revolution.

For the organization of the line in this country, see ARMY OF THE UNITED STATES. In addition to this, a few facts may be given: The general orders of 19 May 1877 fixed the strength of the infantry at 9,575 men, in 25 regiments. The pay ranges from \$3,500 a year for the colonel to \$13 a month for the private. The appointments are made from the United States Military Academy, from the ranks after two years' service and severe examinations, or from civil life if there are no eligibles in the others. The arms are the Krag-Jorgensen and the new Springfield magazine rifle, with knife-bayonet. The equipment is knapsack, haversack with implements for meals, canteen, blanket wrapped in piece of shelter tent, and waist-belt with cartridges.

Infection, the introduction of disease-producing micro-organisms in the body. Infection may result in a number of different ways. Micro-organisms may be introduced by means of direct injury. When a person falls and cuts the hand, the bacteria of pus-production or of tetanus may be so introduced, and blood-poisoning or tetanus may develop. Many infections come by means of the intestinal tract. Thus typhoid is commonly obtained from milk or drinking-water. The intestinal worms, tape-worm, roundworm, are contracted in this manner, and a number of other parasites, particularly the trichina, may come from infected food taken into the alimentary canal. Infection may also occur by means of the air-passages. The bacillus of tuberculosis is most often taken into the body in this way, and finding suitable soil, it causes the development of the dread disease. The bubonic plague is frequently contracted through the disease-germ entering the air-passages. At the present time it is deemed not unlikely that a number of infectious diseases, notably influenza, diphtheria, scarlet fever, measles, whooping-cough, are contracted through the respiratory tract by infection with the exciting cause. Occasionally direct contact seems necessary for infection, as in gonorrhœa and syphilis. In malaria, and probably in yellow fever, the active agent that causes the disease is introduced into the body by the bite of an insect, the mosquito. In malaria one particular genus (*Anopheles*) serves as an intermediate host in the developmental history of the parasite, in a manner analogous to the history of the development of a number of the intestinal worms. It is not unlikely that a large number of diseases may be disseminated by the bites of insects of one kind or another. In all the infectious diseases the element of a real, live, and active contagion should never be overlooked. Infectious diseases do not spring out of nothing. There must be some sort of contact in order that a person become infected. A most important part of the treatment of all infectious diseases is the protection of other people by proper care of all one's own excretions during sickness. The doctrine so frequently taught by some that sickness is ignorance is an important half-truth. But for the ignorance of people concerning the proper care of those afflicted with infectious diseases with reference to the protection of others, measles, diphtheria, scarlet

INFIDEL — INFINITE

fever, whooping-cough, typhoid fever, consumption, and a number of other maladies would be entirely eradicated from civilized communities.

Infidel, in modern parlance, one who deliberately rejects the Christian faith after obtaining knowledge of it. In former times a man might be an infidel who had never heard of Christianity. *Infidelis* in ecclesiastical language means "unbelieving," and is applied to unevangelized heathen as well as doubters and apostates. Thus in the Roman Catholic Church a bishop *in partibus infidelium* merely means a bishop whose diocese is set in heathen countries.

Infinite, a term in metaphysics, which means a reality which has no limit or boundary, in time or space. The idea of the infinite is as old as the Ionian philosophy, when Anaximander (610 B.C.) declared that the one in the many, the basis of being in Nature, was *τὸ ἄπειρον*, the infinite. The reality of infinitude has been the source of much controversy, and the tendency of many modern philosophers is to deny it. "An infinite number," says Bosanquet, "would be a number which is no particular number, for every particular number is finite. It follows from this that infinite number is unreal." On the other hand F. H. Bradley states the contrary, in the clearest terms, "We may be asked whether Nature is finite, or infinite. . . . if Nature is infinite, we have the absurdity of a something which exists; and still does not exist. For actual existence is, obviously, all finite. But, on the other hand, if Nature is finite, then Nature must have an end, and this again is impossible. For a limit of extension must be relative to an extension beyond. And to fall back on empty space will not help us at all. For this (itself a mere absurdity) repeats the dilemma in an aggravated form. But we cannot escape the conclusion that Nature is infinite. And this will be true not of our physical system alone, but of every other extended world that can possibly exist. . . . Every physical world is, essentially and necessarily, infinite."

It seems as if Aristotle had a clearer and more logical view of infinity, *τὸ ἄπειρον* than many modern Positivists, such as Bosanquet. He says, *λειτεραὶ οὐν τυδεῖς εἰναι τὸ ἄπειρον*. He means of course, that, with regard to finite human intelligence, the infinite remains unrealized, although logically it could be realized, and of course, when we speak of infinite time, or infinite creative change in nature, we speak of something which potentially exists, but is only gradually becoming actual.

Infinity is also applied to the divisibility of matter. This is termed "infinite fission." If an atom is divided into two parts, and each of these is again divided into two parts, the mind cannot conceive of any individual fragment resulting from this division as incapable of being divided.

Professor Royce of Harvard has undertaken the task of vindicating the concept of the actual Infinite against the charge of self-contradiction. He is controveering Mr. F. H. Bradley of Oxford, who while he admits "we cannot escape the conclusion that Nature is infinite," expresses also his belief that such an assertion is a contradiction in terms. Professor Royce accomplishes this vindication by proving the following theses:

1. The true Infinite, both in multitude and in organization, although in one sense endless, and so incapable in that sense of being completely grasped, is in another, and precise sense, something perfectly determinate. Nor is it a mere monotonous repetition of the same, over and over. Each of its determinations has individuality, uniqueness, and novelty about its own nature.

2. This determinateness is a character which, indeed, includes and involves the endlessness of an infinite series; but the mere endlessness of the series is not its primary character, but simply a negatively stated result of the self-representative character of the whole system.

3. The endlessness of the series means that by no merely successive process of counting, in God or in man, is its wholeness ever exhausted.

4. In consequence, the whole endless series, in so far as it is a reality, must be present, as a determinate order, but also all at once, to the absolute experience. It is the process of successive counting, as such, that remains, to the end, incomplete, so as to imply that its own possibilities are not yet realized. Hence, the recurrent processes of thought reveal eternal truth about the infinite constitution of real Being,—their everlastingly pursued Other; but themselves,—as mere processes in time—they are not that Other. The true Other is, therefore, that self-representative system of which they are at once portions, imitations and expressions.

5. The Reality is such a self-represented and infinite system. And herein lies the basis of its very union, within itself of the one and the many. For the one purpose of self-representation demands an infinite multiplicity to express it; while no multiplicity is reducible to unity except through processes involving self-representation.

6. Nevertheless, the Real is exclusive as well as inclusive. On the side of its thought the Absolute does conceive a barely possible infinity, other than the real infinity, a possible world, whose characters, as universal characters, are present to the Absolute, and are known by virtue of the fact the Absolute thinks.

This brings metaphysics face to face with the notion of a Supreme Being, who is infinite or absolute. With the mystics God is infinite love, joy and wisdom to his human children. The Hindus taught that God was the infinite universe, the Other, the reality. "That (that is, the Universe) art thou," was their dictum. Christianity teaches that "God is of infinite power, wisdom and goodness," of which qualities the best of men have but a finite endowment.

The term "infinite" was introduced into geometry by Kepler in his 'Nova Stereometria Doliorum; accessit Stereometria Archimedea Supplementum.' Thus he considered a circle as formed by an "infinite" number of triangles, having their vertices at the centre, and their bases at the circumference. A cone likewise, he taught, was composed of an "infinite" number of pyramids, having their vertices at the vertex, and standing on an "infinite" number of triangular bases, bounded by the circular base of the cone. In this sense infinite means incommensurable, not to be expressed by a finite mathematical formula. Consult: Bradley, 'Appearance and

INFINITIVE — INFLAMMATION

Reality'; Royce, 'The World and the Individual'; Bosanquet, 'Logic'; Couturat, 'L'Infini mathématique.'

Infin'itive, the indefinite mode in which the verb is represented without a subject. As the verb expresses an action, or a state, it generally belongs to a subject whose action or state is expressed; but if we wish to express the mere idea of this action or state we use the infinitive, which, therefore, in many languages is employed without further chance as a substantive—for instance, in Greek and German—only preceded by the neuter article; but as the verb expresses an action or state under certain conditions of time, the infinitive can also express the action or state in the present, past, or future, though these conditions are not expressed in all languages by peculiar forms. Some languages have not even a peculiar form for the infinitive, and must express it by some grammatical contrivance, as is the case in English, where it is denoted by *to* prefixed to the general uninflected form of the verb, as *to love* = Latin *amare*; *to have loved* = Latin *amavisse*. The infinitive may be regarded as the point of transition from a verb to a substantive, and is often used as the subject of a proposition. Like a noun, also, it is often used as an object, as I love *to ride*.

Infin'ity, and the Infinitesimal. See INFINITE.

Inflammation, a term long used to indicate the phenomena that follow mechanical, chemical, or physical injuries to living tissues. These changes have been described for centuries as rubor (redness), calor (heat), dolor (pain), and tumor (swelling), which are the phenomena particularly seen on surface inflammations. At the present time the idea is becoming fixed that inflammation is a conservative process, the phenomena attending nature's effort to rid the tissue of harmful substances. In the normal process of repair of an injury there are changes which closely resemble the milder types of inflammation; but when to a mechanical, chemical, or physical injury there is added a growth of micro-organisms, the reply on the part of the body-cells differs from the ordinary repair of injury. The changes witnessed depend upon the strength and kind of invading micro-organism and the particular tissue invaded. The first change is *hyperemia*, a suffusion of the part with blood from capillary dilatation; following this the liquid part of the blood, the serum, is poured out into the tissues and offers its resisting powers to the poisonous substance. If these measures be insufficient, the white blood-cells called phagocytes congregate in the tissues, destroying the invading organisms, by actually consuming them and neutralizing their toxic products. During this struggle there is more or less death of the cells, called "degeneration"; large masses "slough"; the remnants of the cells and the phagocytes killed form the thick fluid called pus. When an inflammation goes on to the formation of pus, it is spoken of as *purulent* or *suppurative*. Certain poisons cause a peculiar reaction on the part of the tissues, characterized by the formation of new tissue that is unable to carry on the function of the part. This tissue is the same as the connective tissues, and the process is called *productive inflammation*. The poisons that continue to act for a long time are

particularly apt to cause this reaction, and the inflammation is called *chronic* because of its permanency. Catarrhal inflammations are these same processes when they occur in mucous membranes; the appearance of these catarrhs, however, is different, owing to the peculiar structure of mucous membrane and to the fact of the epithelial covering offering excellent resistance to invasion. When death of cells occurs they can readily be cast off. Croupous inflammation is the term used to describe those in which there is considerable destruction of the superficial layers of the mucous membrane, which, with the fibrin of the blood, forms a coating or "false membrane" on the surface. Granulation tissue (q.v.) is the name applied to the tissue formed during the repair of an injury. Names are given to certain types of inflammation having a characteristic appearance to the naked eye, but microscopically there is nothing absolutely distinctive in these except their arrangement. Particular examples of these are tubercular and syphilitic inflammations.

The majority of the diseases of the body that we recognize as entities are due to inflammation in some tissue or organ, but the picture depends on the various changes in the functions of different parts of the body. The kind and virulence of the generated poison, together with the reaction on the part of the body-tissues, makes the complete picture that we seek to recognize. The treatment of inflammation is, in large part, the practice of medicine and surgery. Efforts to help the tissues combat against invasion are made with more success as knowledge is gathered of the peculiar invading forces and the natural modes of defense. It is not that we wish to combat the inflammation *per se*, but rather to make it unnecessary by helping it to a successful issue. The actual destruction of the bacteria by drugs introduced into the body is of little use, for they would be apt to cause as much destruction of the body-cells as of the invading cells; but their toxines, which cause the actual damage, we are learning to neutralize by the administration of artificially prepared antitoxins, and by placing the body and its special tissues under the most favorable conditions for developing its natural forces of resistance.

In exposed parts of the body, where antisepsics may be applied, the toxic germs may be killed, and various measures that change the blood-supply may be advantageous. Where death of tissue takes place, nature may require help in its removal. It has long been the rule to evacuate pus wherever it is formed, unless its escape from the tissues is easy.

The treatment of chronic inflammation is entirely different, as this is a process where actual structure is changed beyond repair in many instances. The all-important question is whether the tissue can carry on its proper functions; for if it can, the body need not suffer. The inflammatory process is arrested in its progress by the removal of the irritating cause, by improving the blood-supply of the part and the vitality of the body generally. These constitute the measures in general applied for the cure of chronic inflammations, it being understood that the endeavor is to place the tissues in such a condition that they may carry on their functions for the good of the whole organism; and the failure of these measures shows either that they are at

INFLEXION — INFLUENZA

fault or that the tissue-change has gone too far. Inflammation of any part is indicated by adding the suffix "itis" to the name of the organ or tissue. See BRONCHITIS, COLITIS, LARYNGITIS, MENINGITIS; etc.

DUDLEY D. ROBERTS, M.D.,

Inflexion (Latin, *inflexio*, a bending), that process in grammar which modifies words when placed in relation to other words in a sentence. Pronominal and predicative roots are combined to form one word in the Semitic and Aryan tongues, which are therefore called inflexional, a process impossible in monosyllabic languages like the Chinese or in languages of the agglutinate order like those of the Turanian family. In grammar, cases, numbers, persons, tenses, etc., are known as inflexions, and in many instances the original affixes can be readily recognized. The Semitic and Aryan families of languages, which admit of phonetic corruption both in the root and the terminations, are called organic or amalgamating languages. The pronominal termination varies according to the person or number. Thus the Sanskrit *mi*, *si*, *ti*, the endings of the three persons singular of the present of the verb, are perhaps from the personal pronouns *ma*, *sva*, *ta*, and the persons of the plural indicate the plural number by the form of the pronominal affixes. The plural of masculine and feminine Greek and Latin nouns of the third declension is probably a contraction of the duplication of *sa*, the pronoun of the third person. The verbs *i*, to go, *as* and *fu*, to be, supply the inflexions of certain tenses of the verb, there being also a pronominal termination varying according to the person. In English the common auxiliary verbs am, do, have, shall, will, may, can, asserting respectively existence, action, possession, obligation, volition, liberty, power, assume the function of inflexions, and are themselves inflected to denote past time. In French the same inflexional law exists, the connection between the auxiliary and the root being closer than in English. *Aimer-ai*, I have to love, that is, I shall love, is compounded of the infinitive *aimer*, to love, and *ai*, I have, the first person present indicative of *avoir*. The same is the case in Italian and Spanish.

Inflorescence, Infruktescence, botanical terms referring respectively to methods of flowering and fruit-bearing. The flowering shoot, says Strasburger, frequently bears only a single flower, which may then be either axillary or terminal. In many cases, however, the metamorphosis of the generative region, which results in the production of flowers, has led to the formation of a special system of fertile shoots termed an inflorescence or, after the fruit is formed, an infruktescence. (See FLOWERS; FRUIT.) Such inflorescences are wanting or ill developed among the Gymnosperms, while in the Angiosperms they are often well differentiated, constituting unities of a higher order. The modifications exhibited by the fertile shoots of such an inflorescence are due, partly to a difference in their mode of branching, partly to the reduction or the metamorphosis of their leaves. These changes are the result of an adaption to pollination, in the endeavor to aggregate the flowers and at the same time render them more conspicuous by the reduction of the foliage-

leaves. Sometimes the whole system of fertile shoots is converted into an attractive apparatus, as in the *Araceae*, where the axis and the subtending leaf of the inflorescence have assumed the function, usually exercised by the perianth, of enticing insects. Viewed from a purely morphological standpoint, two types of inflorescences may be distinguished, the Botryose (racemose, monopodial) and the Cymose (sympodial).

Influenza, la grippe; an epidemic catarrhal fever, now believed to be due to a very minute bacillus that can be found in the various secretions. Epidemics of this disease have been traced back as far as the beginning of the 16th century, and since 1741 many such epidemics spreading over portions of Europe have been described. There are so many different types of the disease, and so many parts of the body may be distinctly attacked by it that it somewhat baffles close definition. The epidemics vary much in severity as well as in type. During the last decade it has become almost constantly present over portions of the United States, in some years being much worse than in others.

So great is the variation of its symptomatology that no standard description can be given, and the types are classified according to prominent features. After one to four days of incubation, the disease usually sets in abruptly with chilliness or true rigor; this is followed by a fever (which may be constantly low or may run very high), headache and general aching, and a degree of prostration out of proportion to any discoverable cause. The respiratory form is characterized by inflammation of the nasal, the pharyngeal, the laryngeal, the tracheal, and the bronchial membranes. Starting in the nasal mucous membrane, the inflammation is apt to involve the other membranes in the order given. It is quite common for the lungs to show small spots of bronchopneumonia. There is frequently nothing to distinguish such an influenza from similar acute catarrhs of the respiratory passages except the known presence of an epidemic and the disproportionate prostration. The gastrointestinal form is characterized by nausea, vomiting, abdominal pain and profuse watery discharge, with prostration sometimes amounting to collapse. The typhoid form is characterized by the sudden development of rather high fever (with or without severe aches and pains), general apathy, or even a low muttering delirium. The fever runs from a few days to two weeks, and may very closely resemble typhoid. The nervous form is characterized by severe pains throughout the entire body, prostration, moderate fever, but no definite affection of any part or organ. The meringeal form is characterized by headache, fear of light, pain and stiffness of the muscles of the back of the neck.

Complications and extension of the inflammation to other parts are common. Pneumonia complicating influenza is rather apt to be very severe, and in some epidemics the mortality rises very high. Pleurisy is quite common. Great disturbance of the heart's action is seen in some cases, and the poison may actually attack the lining membrane of its chambers. Less commonly there is inflammation of the eye, ear, brain, liver, intestine, or kidneys. The skin is sometimes affected, showing a general blushing rash, herpes (small painful itchy blisters), or bloody patches. A very common sequel is great

nervous depression, either an inability to make bodily or mental exertion or "low spirits," even amounting to true melancholia. Unless influenza is epidemic, differential diagnosis may be very difficult, but hasty refuge in a diagnosis of "grippe" is far too common; in doubtful cases search should be made for the specific bacillus and considerable reliance placed on the presence or absence of the characteristic symptom, extreme weakness.

For the disease there is no specific treatment; the infecting organism must continue to grow until the natural defenses of the body overcome it; as yet no means has been discovered of killing the bacillus in the body or overcoming its poisons by an antitoxin. Careful isolation of the affected individual will prevent the spread of the disease to other members of the family, and much can be done for the patient's relief. Useful measures consist in securing thorough action of the bowels, keeping up the nutrition by simple, easily digested foods, and the administration of drugs such as phenacetin, acetanilid, caffeine, and bromides to relieve the distressing pains or nervous tension. The nervous exhaustion which is apt to follow is best treated by a period of mental rest, nourishing diet, and little or no bodily exertion.

DUDLEY D. ROBERTS, M.D.,
Brooklyn, N. Y.

Infor'mer, a person who sues for a penalty against those who have infringed any law or penal statute. To encourage the apprehending of certain felons, guilty of offenses not so much criminal as bordering on criminality, many English statutes, from 1692 downward, granted rewards to such as should prosecute to conviction. The penalty in whole or in part inflicted in the case of a successful conviction, and immunity from certain troublesome parish offices, were the inducements held out to informers. In many cases this practice has been resorted to in modern statutes. In the United States one who informs the government of the whereabouts of smuggled goods, counterfeit money, etc., is rewarded by a fee of ten per cent of the net value of the confiscated goods. In criminal law an informer is said to turn state's evidence (q.v.).

Infu'sion, in pharmacy, an aqueous solution of a medicinal substance obtained by treating with water, usually without the aid of boiling. The water may be either hot or cold, varying with the object to be obtained. According to the directions of the United States Pharmacopoeia, infusions are generally prepared by pouring boiling water upon the drug and macerating in a tightly closed vessel until the liquid cools. The active principles are in this manner extracted more rapidly and, as a rule, in much larger portions than if the solution is colder. Heat is not advisable if the active principles are volatile. If an infusion is desired of a greater degree of concentration than that obtained by the process of maceration, it is frequently prepared by percolation, in which operation the drug is sliced or broken up into small fragments, packed in a percolator, and the water, either hot or cold, is passed through. Infusions are sometimes made with the aid of other liquids than water, but this is the exception rather than the rule. Infusions do not keep well, and therefore they should be made extemporaneously and

in small quantities. In household medicine, infusions are very widely employed. These may be made at home or made by the pharmacist. It is essential to remember that if they are made in hot weather in large quantities they must be sterilized.

Infusion of saline solution into the blood-vessels is a very important procedure in medicine. It is employed largely in the treatment of shock, and in severe hemorrhage, especially following operations or childbirth. The solution that is used is known as a normal salt-solution, and consists of about one teaspoonful of common salt to a pint of water. This solution should be boiled carefully for one half to three quarters of an hour, the amount of evaporating water being made up as the boiling proceeds, and after being made it should be kept in large bottles provided with cotton plugs for stoppers. In severe cases of hemorrhage, infusion has often saved life, as it provides a body of fluid on which the heart and blood-vessels can act. The salt-solution is usually introduced into one of the large veins of the arm at a temperature of one to two degrees above that of the body-temperature. See BLOOD; TRANSFUSION.

Infuso'ria, Protozoa of the classes *Flagellata* and *Ciliata*, originally so-called from abounding in organic infusions. While the term is now restricted to the ciliate protozoans, it often includes the flagellate protozoans as well. The latter are represented by the monads. These are exceedingly minute round or pear-shaped animals, which move by one or two lash-like processes called flagella. They contain a nucleus and contractile vesicles. Some of them are fixed by a stalk, and are provided with a collar, as in *Codosiga*, out of which the flagellum projects. One of the simplest monads (*Heteromita*) is obtained by placing a cod's head in water at a temperature of about 70° F. In a few days the water will swarm with these monads. The young germs will live in boiling water, but perish at a temperature of from 212° to 268° F., while the adults are destroyed at 142° F.

In the ciliate infusoria the body is more or less flattened and covered with cilia (*Paramecium*, etc.). They have on the under side of the body a slightly defined mouth (or cytostome), which is permanently open, and the food is swept into it by the action of the cilia around it. The mouth leads into a funnel-shaped throat or cytopharynx, which ends in the protoplasm of the body. The food-particles swept into this throat and pressed into the protoplasm form a small enlargement which finally sinks farther in forming the "food vacuole," which, by the flow of the protoplasm, is carried about the body, while the digestible portions are absorbed and the waste matter is cast out at a fixed point,—a sort of vent (cytopype). The fresh-water forms have contractile vesicles, and in certain species the animal possesses so-called stinging rods (trichocysts), which are very minute and are placed vertically to the surface of the cortex; by some students they are supposed to be tactile rather than stinging structures. What correspond to the muscular fibres of the higher animals, cause the quick convulsive movements observed in these creatures. Two important organs are present in all ciliate in-

INGALLS—INGERSOLL

fusoria, that is the nuclei. The larger nucleus (macronucleus) is an oval, rod-like or spiral body, which appears to control the processes of feeding and motion. The other nucleus (micro-nucleus) is much smaller and is concerned with reproduction. Reproduction occurs usually by self-division, and more rarely the infusorians contract into a ball and divide into spores, which grow to become adults. The periods of fission are at times interrupted by the process of conjugation, which only differs from sexual reproduction in the fact that two individual infusorians meet and fuse together and then separate, the result being a process of fertilization which leads to a complete new formation of the nucleus, and thus to a new organization of the animal. (For a more detailed account see Hertwig-Kingsley's 'Zoology' 1903).

The more specialized infusoria are *Stentor* and *Vorticella*. The former is large enough to be seen without a lens. It is purplish, and under the microscope shows itself to be a beautiful creature. It is trumpet-shaped, with a spiral tract of thicker cilia around the mouth-end. The most highly organized Infusoria are the bell-animalcules (*carchesium*, etc.), which are compound bell-shaped forms, forming colonies with forked branched stalks. The nucleus is sausage-shaped, and near it is the micronucleus. They form a white mass like mold on the stems and leaves of aquatic plants. Some of the infusoria are parasitic in the digestive and circulatory organs of the higher animals. Many of the species are cosmopolitan; this is due to their great vitality, since they may dry up, and their bodies float about in the air in wind currents, and thus conveyed over the earth, reviving again when falling into the water. Consult: Stein, 'Organismus der Infusions-Thiere' (1859-83); Saville Kent, 'Manual of the Infusoria' (1880-2); M. Hartog, 'Protozoa' (Vol. I., Cambridge Natural History, 1903); Ray Lankester, 'Treatise on Zoology' (1902); Hertwig-Kingsley, 'Zoology' (1903).

In'galls, John James, American lawyer: b. Middleton, Mass., 29 Dec. 1833; d. Las Vegas, New Mexico 16 Aug. 1900. He was graduated from Williams College in 1855, and was admitted to the bar in 1857. In 1858 he moved to Kansas and established a law practice there. He was secretary of the territorial council in 1860, and of the State senate in 1861, and in 1862 was elected a member of the senate. In 1873 he became a member of the United States Senate, and was re-elected in 1879 and 1885. He was always a strong supporter of the Republican policy, and gained a wide reputation as a public speaker. He was president pro tem. of the Senate from 1887-91. In 1891 he was again a candidate for senator, but was defeated by the Farmers' Alliance. From that time till his death he devoted himself chiefly to lecturing and writing.

Ingalls, Rufus, American soldier: b. Denmark, Maine, 23 Aug. 1820; d. 15 Jan. 1893. He was graduated from West Point in 1843, fought in the Mexican War and in the Civil War, serving with distinction in the Army of the Potomac. He became quartermaster-general of the United States army in 1882 and was retired in 1883.

Ingelow, In'jé-lō, Jean, English poet and novelist: b. Boston, Lincolnshire, 1820; d. Ken-

sington, London, 20 July 1897. Her first published work appeared anonymously in 1850 under the title 'Rhyming Chronicle of Incidents and Feelings.' It was followed by 'Allerton and Dreux: or the War of Opinion' (1851), a story, and 'Tales of Orris' (1860); but not till the publication of 'Poems,' in 1863, did Miss Ingelow become famous. This volume won the enthusiastic praise of critics and the instant approval of the public, and passed through 23 editions. The most widely appreciated poems in it are 'The High Tide on the Coast of Lincolnshire'; 'Songs of Seven'; 'Divided'; and 'Supper at the Mill.' Later volumes were: 'Studies for Stories' (1864); 'Stories told to a Child' (1865); 'A Story of Doom, and Other Poems' (1867); 'Mopsa the Fairy' (1869); 'Off the Skelligs' (1872), her first long story; 'The Little Wonder Horn' (1872), a new series of stories told to a child; 'Fated to be Free' (1875); 'Sarah de Berenger' (1880); 'Don John' (1881); and 'John Jerome' (1886). A third volume of verse, 'Monitions of the Unseen' was published in 1885. Her works have been even more popular in America than in her native country.

Ingersoll, ing'gér sól, Charles Jared, American statesman, lawyer, and author: son of Jared Ingersoll (q.v.); b. Philadelphia 3 Oct. 1782; d. there 14 May 1862. After finishing his collegiate course he studied law, was admitted to practice, traveled in Europe, and became attached to the American embassy to France. In 1812 he was elected to Congress, taking his seat in May 1813. In 1815 he was appointed United States district attorney for Pennsylvania, an office which he held until 1829. Shortly after he was elected to the legislature of Pennsylvania. He was a member of Congress 1841-7 as representative of one of the districts of which the county of Philadelphia was then composed. He was the author of the poems 'Chiornara' (1800), and 'Julian' (1831); and of 'Inchiquin—the Jesuit's Letters on American Literature and Politics' (1810); 'Historical Sketch of the Second War between the United States and Great Britain' (1845-52); etc. Consult Meigs, 'Charles Jared Ingersoll' (1896).

Ingersoll, Ernest, American naturalist: b. Monroe, Mich., 13 March 1852. He studied at Oberlin College and in the Lawrence Scientific School and Museum of Comparative Zoology of Harvard University, where he was a pupil of Agassiz, and in 1874 and 1877 was connected as naturalist with the Hayden survey. He was also an expert on the United States fish commission, and later became known as a popular writer and lecturer on scientific subjects. In 1901 he was lecturer in zoology at the University of Chicago. Among his works are: 'Nests and Eggs of North American Birds' (1880-1); 'Oyster Industries of the United States' (1881); 'Knocking 'Round the Rockies' (1883); 'Country Cousins' (1884); 'The Crest of the Continent' (1884); 'Down East Latch-Strings' (1887); 'Wild Neighbors' (1897); 'The Book of the Ocean' (1898); 'Nature's Calendar' (1900); and 'Wild Life of Orchard and Field' (1902); and also 'The Ice Queen,' and several other popular juvenile tales.

Ingersoll, Jared, American lawyer: b. Connecticut 1749; d. Philadelphia 21 Oct. 1822. Having been graduated at Yale College in 1766,

INGERSOLL—INGRAHAM

he went to London, was entered of the Middle Temple, and passed five years in the study of law. The American Revolution breaking out while he was still in London, he espoused the cause of the colonies, although the son of a loyalist. He went from London to Paris, where he remained for 18 months, making the acquaintance of Franklin. Returning home, he took up his residence in Philadelphia, where he won almost immediately a prominent position as a lawyer. In 1787 he was chosen one of the representatives of Pennsylvania in the convention which framed the United States Constitution. Twice attorney-general of the State, he was United States district attorney for Pennsylvania, and was in 1812 the federal candidate for Vice-President of the United States.

Ingersoll, Robert Green, American lawyer, lecturer and author: b. Dresden, N. Y., 11 Aug. 1833; d. Dobb's Ferry, N. Y., 21 July 1899. He received a common school education and was admitted to the bar in 1854. He soon became prominent in the courts and in Democratic politics. In the Civil War he recruited the 11th Illinois cavalry and entered the army as its colonel. On 29 Nov. 1862, while trying with a force of 600 men to intercept a Confederate raiding party he was captured by a force of 10,000 men, but was soon paroled and given command of a camp in St Louis. He soon afterward resigned. After the war he became a Republican, and was made attorney-general of Illinois in 1866. He was a delegate to the Republican National Convention in 1876 and placed in nomination for President, James G. Blaine, whom he termed "the plumed knight." His nominating speech gave him national reputation as an orator, and he afterward lectured frequently. He was an agnostic, and in his lectures attacked the Bible and the beliefs of the Christian religion. He was prominent in politics for several years, and had he not given such frequent expression to his agnostic views he would doubtless have been honored with high offices. He took up his permanent residence in New York city in 1882 and practised law there till his death. His most famous lectures include "Some Mistakes of Moses"; "The Family"; "The Liberty of Man, Woman, and Child"; "The Gods"; and "Ghosts". His publications include "Lectures Complete" (1886); "Prose, Poems and Selections" (1888); and "Great Speeches" (1887); "Mistakes of Moses" (1879). A complete collection of his works was published in 1900.

Ingersoll, Canada, town in Oxford County, Ont., on the Thames River and the Grand Trunk railroad, 19 miles northeast of London. It has newspapers, banks, a number of churches, and varied industries. Lumber and grain are among its larger exports, and it has manufactures of iron products, machinery, agricultural implements, woolen goods, woodenware, and cheese. Pop. (1901) 4,572.

Ingham, Charles Cromwell, American painter: b. Dublin, Ireland, 1797; d. New York 10 Dec. 1863. He was a pupil of William Cuning at the Dublin Academy, came to New York in 1817, was there a founder of the National Academy of Design (1826), and its vice-president in 1845-50. He became well known as a portrait artist, and De Witt Clinton, G. C.

Verplanck, and Lafayette were among his subjects. His further works include: "Day Dreams"; "The White Plume"; "The Death of Cleopatra."

Ingla, ing'la, Charles, American Anglican bishop: b. New York 1734; d. Halifax, Nova Scotia, 1816. He was ordained priest in England, and in 1765 became assistant minister at Trinity Church, New York. A stout loyalist, he refused to omit from the service the prayer for the king and royal family, and upon the occupation of New York by Washington retired for a time to Long Island. In 1777 he was chosen to the rectorship of Trinity, and in 1783, at the evacuation of New York by the British, went to Halifax in the emigration of the United Empire loyalists. He was consecrated in 1787 bishop of Nova Scotia (with jurisdiction over the other North American provinces), and was the first missionary bishop of the Church of England. He published sermons and pamphlets.

In'got, a small bar of metal formed by casting it in molds. The term is chiefly applied to the bars of gold and silver intended for coining.

Ingraham, ing'grā-am, Duncan Nathaniel, American naval officer: b. Charleston, S. C., 6 Dec. 1802; d. there 16 Oct. 1891. He entered the navy as midshipman in 1812, and became a captain in 1855. While in command of the sloop of war St. Louis he arrived at Smyrna 22 June 1853, and was informed that Martin Koszta, Hungarian by birth, but entitled to the protection of the United States, was a prisoner on board the Austrian brig of war Hussar, then lying near the St. Louis. Ingraham went on board the Hussar, had an interview with Koszta, and learned that he had resided a year and 11 months in New York, where he took the usual oath of allegiance to the United States in July 1852, and was in possession of a legalized copy of a declaration of his intention to become an American citizen; that he had come to Smyrna from New York on business; that on the afternoon of 21 June he was seized by a party of armed Greeks, employed by the Austrian consul-general, carried on board the Hussar, where he was held in close confinement. Ingraham accordingly, on 2 July, at 8 A.M., demanded of the Austrian commander the release of Koszta by 4 P.M., declaring that he would otherwise take him by force. At 11 o'clock the Austrian consul-general proposed to deliver Koszta into the hands of the French consul, to be held by him subject to the disposition of the consuls of the United States and Austria, and not to be delivered without their joint order. As this proposition gave sufficient assurance of the personal safety of Koszta Ingraham accepted it, and the Hungarian was set at liberty. The conduct of Ingraham was fully approved by the government, and Congress by joint resolution, 4 Aug. 1854, requested the President to present a medal to him for his conduct on this occasion. In 1860 he resigned from the United States navy, entered the Confederate service and became a commodore.

Ingraham, Joseph Holt, American novelist: b. Portland, Maine, 1809; d. Holly Springs, Miss., December 1866. After brief experience

INGRAHAM — INHERITANCE TAX

of mercantile life he became teacher in Washington College, Natchez, Miss., and in 1836 published his first book, 'The South-West, by a Yankee.' Thenceforth he produced in rapid succession 'Lafitte'; 'Burton, or the Sieges'; 'Captain Kyd'; 'The Dancing Feather'; and other romances of small literary merit, some of which attained a large circulation. He subsequently entered the Episcopal ministry and was rector of a parish and of St. Thomas's Hall, an academy for boys, in Holly Springs, Miss. He still continued to write, publishing 'Prince of the House of David' (1855) and the 'Pillar of Fire' (1859); 'The Throne of David,' which were widely popular, but nearly worthless from a literary point of view.

Ingraham, Prentiss, American soldier and author: b. Adams County, Miss., 22 Dec. 1843. He was educated at Jefferson College (Miss.), also studied medicine at the Mobile Medical College, entered the army of the Confederate States in 1861, fought later with Juarez in Mexico, with the Austrian army in the war with Prussia, and in the ten-years' war for independence in Cuba. Subsequently he entered a literary career, and published a great quantity of fiction, including: 'Without Heart' (1878); 'Zuleikah' (1887); 'Red Rovers on Blue Waters' (1890); 'The Vagabond' (1891); and 'The Wandering Jew of the Sea' (1891).

In'gram, John Kells, English educator and author: b. County Donegal, Ireland, 7 July 1823. He was educated at Trinity College, Dublin, and was appointed professor of oratory and English literature there in 1852, Regius professor of Greek in 1866, and librarian in 1879. At one time he was vice-provost of the college, and also held the presidency of the Royal Irish Academy. His 'History of Political Economy,' originally printed in the 9th edition of the 'Encyclopædia Britannica,' was separately published in 1888 and widely translated. He further wrote: 'A History of Slavery and Serfdom' (1895); 'Sonnets and other Poems' (1900); 'Human Nature and Morals according to Auguste Comte' (1901), and other works.

Ingres, Jean Dominique Auguste, zhōn dō-mē-nék ö-güst äng-r, French historical painter: b. Montauban 15 Sept. 1781; d. Paris 14 Jan. 1864. Placed in the school of David he made such rapid progress that at 20 he had gained in two successive years the first and second prizes of the Academy of Fine Arts. In 1806 he departed for Italy, where he passed nearly 20 years, abandoning, under the influence of a close study of Raphael and the old masters, the 'dry, classic style acquired from David. His works are numerous, and comprise generally serious historical and classical subjects; in the great exhibition of 1855 at Paris an entire salon was appropriated to them. Many are in the Louvre, on the ceiling of one of the apartments of which is painted his 'Apotheosis of Homer.' He painted the portraits of many distinguished personages, from Napoleon I. downward. The art of Ingres is adjudged to hold a middle place between the classic and the romantic schools.

Inhalation, in medicine, a mode of applying remedies directly to the respiratory tract.

Either steam alone, steam charged with drug-vapors, or drugs finely subdivided in sprays, are breathed into the air-passages as deeply as possible. This method of medication is useful only in relieving inflammations of the upper air-passages and possibly the trachea and larger bronchi. The air in the smaller bronchi is not changed by breathing, but by the diffusion of gases, so that substances in aerial suspension are deposited on the surface before reaching the smaller divisions of the bronchial tubes. Steam does not penetrate far, but is cooled, and deposits moisture as far as the trachea. The old-fashioned croup-kettle and many devices for carrying out the same idea are used for the first stages of laryngitis. Many substances, such as tincture of benzoin, etc., are added to the boiling water, but render it no more efficacious. Instead of conducting the steam directly to the mouth and nose by a funnel or tube, it may be well to place the patient in a simply enclosed tent, formed of bed-clothes, and to allow the steam to charge the confined air. This method is particularly advisable for infants and older children.

Inher'itance, in law, a perpetual or continuing right to an estate invested in a person and his heirs. There are nine "canons of inheritance"; three may be quoted: (1) That inheritance shall, in the first place, descend to the issue of the last purchaser in *infinitum*; (2) That the male issue shall be admitted before the female; (3) That where two or more of the male sex are in equal degree of consanguinity to the purchaser, the eldest only shall inherit, but the females all together.

Inheritance Tax, an assessment laid upon those made heirs of property, either by distribution or descent. Sometimes this assessment is confined to collateral heirs, when it is called collateral inheritance tax. The raising of public funds in this way has been sanctioned by legislation from the beginning of Roman law, and in England and other countries is a large and steady source of revenue, although such taxes have been stigmatized by certain economists as "death duties." During the Civil War taxes of this kind were made part of the internal revenue system of the United States, but abolished soon after the struggle ended. The rate and method of assessment vary in different countries, and in different States of the Union. The English inheritance tax ranges from a 1 to a 10 per cent assessment, in accordance with the amount of the inheritance and the degree of relationship of heirs. In the United States lineal, collateral and succession inheritance taxes have been instituted in several States, as a source of domestic revenue. In Connecticut the assessment on inherited property is 5 per cent on all sums and values above \$1,000. In Delaware the assessment ranges from 1 to 5 per cent, according to the amount of property left, and the degree of relationship. In Illinois, 1 per cent on values over \$20,000 to lineal descendants; 2 per cent to 5 per cent on all amounts to collateral relations. In Maryland, 2½ per cent on all legacies and successions. In New York, 1 per cent on all property over the amount of \$10,000 to lineal heirs, 5 per cent on all amounts over \$500 to collateral relatives. In Ohio, 5 per cent on all values over \$500. In

INIA — INJUNCTION

Virginia, 5 per cent in every case. Several States leave untaxed the property descending or distributed to the lineal descendants, and place assessments of varying percentage on the amount or value of the legacy which falls to collateral heirs. These are California, Maine, Massachusetts, Minnesota, New Jersey, Tennessee, West Virginia. Inheritance laws have in the United States occasioned much discussion and litigation, but their justice and utility have been testified to by experience and the decision of the law courts. The leading economists of the present and the other periods have seen the scientific propriety, even necessity, of such legal provisions, and have noted the uniformity with which they deal with all classes of the financial community.

In'ia, a genus of toothed cetaceans similar to dolphins, but placed on structural grounds in the allied family *Platanistidæ*, with the freshwater dolphins of the Ganges and the La Plata. The single species (*I. gressensis*) is called boutu and tucuxi, and is found in some of the upper tributaries of the Amazon, and in the lakes near the Cordilleras. It measures about eight feet in length, has a long cylindrical snout with stiff hairs, and a very slight dorsal fin. It feeds chiefly on fish, and is hunted for the sake of its oil.

Injunc'tion, a writ issued by a court of equity, bidding, or forbidding, a person or persons to do a certain thing. The injunction originated in Roman law, and was anciently known as an interdict, a name it still bears in Scottish practice. It was introduced as a remedy for some of the abuses of common law, and as a preventive, when evasion of common law provisions seemed possible. It is to-day one of the most potent of the legal remedies of an equitable character which stand on the statute books.

There are three main divisions in the purposes for which a writ of injunction is issued. A writ may be prohibitive, protective, or restorative. In the first place it may forbid the commission of certain acts of a civil nature which are charged with injustice. Second, it may be so framed as to protect such civil rights of an individual or a corporation as seem to be threatened. Third, it may order the restitution or restoration of such rights as have unlawfully been taken away from an individual or a corporation. These characters of the writ have been clearly expounded by Blackstone, as follows:

"This writ may be had to stay proceedings at law, whatever stage they may have reached; to restrain alienations of property *pendente lite*, and tenants for life and others having limited interest from committing waste. It may be granted to restrain the negotiation of bills of exchange, the sailing of a ship, the transfer of stock, or the alienation of a specific chattel, to prohibit assignees from making a dividend, to prevent parties from removing out of the jurisdiction, or from marrying, or having any intercourse, which the court disapproves of, with a ward. The infringement of a copyright or a patent frequently calls for the exercise of this beneficial process; which may also be had to restrain the fraudulent use of trade marks, or of the names, labels, or other indicia of the makers or vendors of goods and merchandise,

and in a large class of cases, far too numerous to be mentioned here."

The first two kinds of injunction are most commonly used, and a familiar example of the prohibitory writ is that which orders the abatement of a nuisance. A railroad which lays tracks without first gaining the right of way may be compelled by injunction to remove them. By such a writ patent rights, copyrights and trade marks are secured from infringement, or proceedings in a court of law are stayed. Sometimes a court of equity issues an injunction prohibiting litigants within its own jurisdiction from prosecuting a suit in another jurisdiction; for example, a United States court may restrain creditors for suing in State courts for the enforcement of their claims against a bankrupt, and reserve the disposition of his estate to its own jurisdiction. A court of equity only issues a writ of injunction when a remedy of law appears inadequate to give the wronged party the complete relief to which he is entitled. Thus in recent cases the courts have issued writs forbidding labor agitators and others from inducing or coercing workingmen, in such a way as to bring on a strike to the injury and damage of employers, who might thus be induced to sacrifice their rights in order to escape ruin or irreparable loss.

An injunction in the United States may be preliminary or perpetual. A preliminary writ is sometimes styled interlocutory, as it is issued *pendente lite*. The preliminary writ may be made perpetual, if, after arguments made and heard, the court decides that the grounds advanced for the continuance are valid, and have been so proved by evidence. Failure to obey an injunction is punishable as a contempt of court (q.v.) Consult Beach, 'Treatise on the Law of Injunctions' (1895).

Injunction, Government by. See GOVERNMENT BY INJUNCTION.

Injunction, Theatrical, a term applied to a mandate issued by a court of equity, to compel or prevent the performance of some act for which money damages would not properly compensate the injured party. Relief by injunction in matters pertaining to theatricals is probably more frequently sought than in any other business or profession, and precedents in law established in this class of cases has become of considerable importance. At first, courts of this country and England refused to grant injunctions against actors for the purpose of compelling them to perform their contracts, a learned justice saying: "The Court could not regard as law the old adage that 'a bird that can sing and will not sing must be made to sing.'" But latterly, when the service of an actor became recognized and it was made to clearly appear that an actor or singer, by intelligence, education and other artistic accomplishments and talents, was of extreme importance to one who had invested money in the production of a play or opera, it was held that a court of equity would by injunction enforce a covenant in a contract. But this has simply gone to the extent of compelling a fulfilment of the contract, or forcing the artist to remain idle during its term. The services of every actor will not be enjoined. He must actually possess some exceptional merit, so that his services may be

INK

termed special, unique and extraordinary, and it must be shown they cannot be fulfilled by any other person without injury to the employer. In the case of *Lumley v. Wagner*, the courts of England enjoined Johanna Wagner, a prominent prima donna of the early 50's from appearing at Covent Garden Opera House, London, in violation of her contract with Lumley; and then for the first time the British courts asserted their authority over contracts of actors, and granted an injunction forbidding her rendering professional services for any but her original employer.

In the United States, the Federal courts recognized the right of a manager to have the exclusive services of his employee, and in *McCall v. Braham* an injunction was granted which prevented Lillian Russell from violating her contract. In the State courts, the case of *Augustin Daly v. Fanny Morant Smith* (49 How. Pr. 150), Superior Court Justice Freedman also appreciated the fact that the ancient rule had been abrogated and the modern one compelling actors to live up to their agreements, as other individuals, was there enforced. The contract must unquestionably be fair. The rights of both parties to it must be equal. In other words, if the contract gives the manager the right to terminate it by giving notice before the expiration of the contract, a like right of termination must also be given the actor; and as stated before, the actor's services must be special, unique and extraordinary. In this latter connection, it seems uncertain where to draw the line. In the case of *Carter v. Ferguson* the court refused to grant an injunction to Mrs. Leslie Carter against William J. Ferguson, an actor, saying that his services were not so special and unique as to warrant a court of equity's interference. In *Charles Hoyt v. Loie Fuller*, the court granted an injunction against the dancer, holding that a serpentine dance in the performance of which she became famous, warranted the court's interference by injunction. In *George Edwards, the London manager, v. Cissie Fitzgerald*, the New York Supreme Court granted an injunction against Miss Fitzgerald, on the theory that a certain wink of her eye used in a play was of special merit, and a drawing card. In *Harris v. Sparks*, an injunction was granted against John Sparks, the Irish comedian, the ground being that his portrayal of an Irish character was special, unique and extraordinary. While in the still later case of *Shubert Brothers v. Aimee Angeles*, imitations given by the performer were considered so special, unique and extraordinary as to warrant the granting of an injunction. Each case, however, must be determined by its own peculiar circumstances. In the most recent case—*Harrison Grey Fiske v. Tyrone Power*—the court refused to grant an injunction against Tyrone Power, although his ability as an actor was exploited in the newspapers; on the ground that his services were not so special, unique and extraordinary, as to justify an injunction. But in guarding the rights of an actor, the courts will see that no advantage has been taken of him by the manager, and that the manager for whom he is to perform is of such financial responsibility as to insure the salary of the actor. In the case of *Rice v. D'Arville*, Edward E. Rice,

the theatrical manager, sought to restrain Camille D'Arville from performing for others; but on the defense that Rice was insolvent and indebted to her on a previous contract, Justice Oliver Wendell Holmes, then of the Massachusetts Supreme Court, would not compel her to perform for Rice.

Injunctions in the theatrical profession are not confined to actors and actresses, but are often invoked to prevent the piracy of a play or the use of a name. Where a play, or a scene from a play, has been copyrighted, the Federal courts alone have jurisdiction of the matter, and will by injunction prevent anybody from performing or producing it as their own. When there has been no copyright the common law protects the work, so well as its title; and the use of a similar name, or a name which is apt to deceive the public into the belief that it is the one already used by an author, will likewise be enjoined. A recent instance is the case of *Charles Frohman v. Arthur Fraser*, where the use of the title "Sherlock Holmes" was enjoined, this name having been adapted by William Gillette as the title of a play, notwithstanding the name had been used by A. Conan Doyle as the title of his novel. In that case the court held that Mr. Gillette having first used the name in connection with a theatrical production was entitled to all emoluments arising from it. Notwithstanding the numerous attempts to avoid the principles of law applicable to this class of cases, it matters not whether it is the actor who is involved or the theatrical manager, the American courts are humane, equitable, just and careful, and invariably zealously guard the interests of those engaged in the theatrical profession, so well as those engaged in any commercial business.

ABRAHAM H. HUMMEL,
Counsel in U. S. for Société de Auteurs Français.

Ink, a colored liquid used for writing and printing. They are of various classes, as writing and copying, black or colored, India, printing and lithographing inks.

For long ages past the best black writing-ink has been made by mixing together solutions of nutgalls and of ferrous sulphate of iron, known as green vitriol, and holding in colloidal suspension, by aid of a gum, the colored substance produced. The gallo-tannic acid present in a freshly prepared solution of gall, upon exposure to the air, changes gradually largely into gallic acid, and the protoxide of iron changes into peroxide. The color of this changed product is much deeper than that of the original mixture. It has been found that the permanency of the writing is greater if the ink is used before this conversion is fully completed. The change is held in check by having present in the ink a slight amount of some free volatile acid such as hydrochloric. The trace of acid also serves to hold the iron color in the state of colloidal suspension or solution. The moulding to which such an ink is liable is checked by adding to it a trace of some antiseptic, such as carbolic acid. All known commercial substitutes hitherto used for nutgalls in black writing-ink produce a fluid somewhat inferior to that from nutgalls.

An exhaustive scientific investigation of the chemistry of ink to determine the best ingre-

INKBERRY — INLAYING

dients and the proportions to be used of the same for the producing of the most permanent black writing-ink has been made in Germany by Osw. Schlüttig and Dr. G. S. Neumann, and published in their work on 'Die Eisengallustinten,' issued by Zahn & Jaensch of Dresden in 1800. Their conclusions were followed in preparing the specifications for the official "Standard Record Ink" required under the laws of Massachusetts to be used on all the public records in that state. The same specifications have since been adopted by the U. S. Treasury for the ink used in that department. This ink has also been adopted by the Danish government for its official records. The specifications, which were prepared by Dr. Bennett F. Davenport of Boston, as ink expert for the State of Massachusetts, it is to be noted are for the required quality of the ink, and not for the compounding of it. The specifications are as follows:

It must be a gallo-tannate of iron ink, not inferior in any essential quality to a typical standard for comparison which has been properly prepared after the following formula, in which all the ingredients are of the quality prescribed by the United States Pharmacopeia, and the per cent of true acid present in the sample of tannic acid used has been determined by the Loewenthal and Schroeder method.

Take of pure, dry Tannic Acid, 23.4 parts by weight; crystal Gallic Acid, 7.7 parts; Ferrous Sulphate, 30.0 parts; Gum Arabic, 10.0 parts; diluted Hydrochloric Acid, 25.0 parts; Carbolic Acid, 1.0 part; Water, sufficient to make up the mixture at the temperature of 60° F. to the volume of 1000. parts by weight of water.

Inks submitted will be subjected to the following tests, as compared with the typical normal standard ink described above: (1) A fluid ounce allowed to stand at rest in a white glass vessel, freely exposed in diffused daylight for two weeks to the light and air, at a temperature of 50° to 60° F., protected against the entrance of dust, must remain as free from deposit upon the surface of the ink or on the bottom or sides of the vessel. (2) It must contain no less iron, and must have a specific gravity of 1.035 to 1.040 at 60° F. (3) It must develop its color as quickly. (4) After a week's exposure to diffused daylight the color must be as intense a black when used upon the standard record paper, and it must equally resist changes from exposure to light, air, water, or alcohol. (5) It must be as fluid, flow as well, strike no more through the paper, nor remain more sticky immediately after drying.

To such an ink a slight amount of some one of the water soluble coal-tar colors is usually added to give the desired initial color to the ink when used in writing.

Cheaper grades of black writing-ink are produced by substituting for the nutgalls other tannin containing substances, or by using logwood. In these other iron salts, or salts of other metals are sometimes used, as of copper, aluminum or chromium. For special purposes some of these have certain advantages. For copying, for instance, the ink made from logwood with alum cake and chromate has the highest efficiency known. This ink, however, fades out after a few years' exposure to the open air and daylight.

Within modern times colored liquid solutions have come much into general use as inks, made up with aniline and other dyestuff colors. They are easily and cheaply made, flow nicely from the pen, and allow of a great variety as to choice in coloring, but none of them have the permanency of the ancient nutgall iron ink on exposure to light and air.

The usual basis of commercial marking inks, for use on textile fabrics, is some salt of silver. The permanent color of this ink is developed through the action of light, heat or some chemical, after the ink has been applied. The usual basis of India ink is an exceedingly finely di-

vided solid carbon, mixed with a size to hold it in suspension when the ink is prepared for use by being ground up with water. The usual base used for printers' ink is a linseed-oil varnish. To this the desirable color is imparted by the use of lampblack, or some other coloring substance.

Manual' (1904); Fehling, 'Handwörterbuch Chemie' (1903) vol. VII.; Haldane, 'Workshop Receipts,' series 2 and 5. BENNETT F. DAVENPORT, M.D., *Expert on Written Documents, the Writing, Ink and Paper.*

Inkberry, or Winterberry, a shrub (*Ilex glabra*) of the holly family which grows upon the Atlantic coast of the United States. It is a fine evergreen, two to four feet high. Its stems are slender and flexible, and its leaves, about an inch in length, are lanceolate in form, of leathery texture, and present a shining upper surface. It bears small, very black berries. Formerly its bark and leaves were used medicinally, especially in fevers. For bouquets and decorative purposes it is much valued, and finds a ready market in large Eastern cities.

Inkerman, īnk-ēr-mān', Russia, a village on the site of a ruined town in the Crimea, at the head of the harbor of Sebastopol, 35 miles by rail southwest of Simferopol. It gives its name to the sanguinary battle fought on the heights overlooking the town, on 5 Nov. 1854, when the Russians unexpectedly attacking the British camp were repulsed with great slaughter, losing in killed 3,000 and in wounded 6,000, the loss of British and French allies being 850 killed and 3,500 wounded.

Inlaying is the art of ornamenting flat surfaces of one substance by inserting into them pieces of some other substance. Various kinds of metal or wood, or pearl, ivory, etc., are employed in this process, which is now applied chiefly to the production of ornamental articles of furniture. When wood of one color is inlaid with others of different colors, as in ornamental devices in flooring, it is generally called marquetry, the various pieces of wood being usually disposed in regular geometrical figures. The art of inlaying iron or steel with other metals, as gold or silver, is called damascening. Buhl and reisner work, once highly prized, have lost much of their celebrity. The former took its name from Buhl, an Italian resident in Paris in the reign of Louis XIV., and the latter was designated after Reisner, a German who not long after settled in the same city. Buhl for the most part inlaid brass on tortoise-shell, Reisner a dark wood on a tulip-wood ground. The usual instrument for cutting out veneers for inlaying is a fine saw, mounted in a bow or arched handle, and worked in short quick movements. Three or four veneers are sometimes cut simultaneously in this way. Inlaying with stone, in which the Florentines have long excelled, is called *pietra dura*, and differs from mosaic in having the holes not cut through the ground, which is commonly of black marble, but only to a regulated depth.

INMAN — INNESS

The best work of this kind is now produced at St. Petersburg, the art being stimulated by encouragement from the Russian government. An Indian variety of inlaying, in which the inlaid metal occupies more of the surface than that which forms the ground, is called *Kuftgari*; and in another variety, *Tutenague* or *Bederywork*, small pieces of silver are hammered into spaces previously cut in the ground, which consist of one part of copper to four of pewter, and is thus both hard and easily cut. See MOSAIC.

In'man, Henry, American artist: b. Utica, N. Y., 20 Oct. 1801; d. New York 17 Jan. 1846. From early boyhood he manifested a taste for art, and in 1814 Jarvis, the portrait painter, offered to receive him as a pupil, and he was bound an apprentice for seven years. Upon the conclusion of his apprenticeship he devoted himself to portrait painting. Among his most characteristic portraits are those of Chief Justice Marshall and Bishop White. He painted also landscape, genre, and history. In 1844 he visited England, where he was the guest of Wordsworth, whose portrait he painted, and at whose suggestion he executed his 'Rydal Water,' near the poet's residence. During his residence in England he also painted portraits of Dr. Chalmers, Lord Chancellor Cottenham, and Macaulay.

Inn, a river of Europe which issues from a lake at the foot of the Rhætian Alps, flows northeast through the deep and narrow valley of the Engadine, in the Swiss canton of the Grisons, enters the Tyrol at Martinsbruck, passes Innsbruck, Hall, and Kuffstein, and shortly after enters Bavaria. At Muhldorf it turns east till it receives the Salza, where it begins to form the boundary between Austria and Bavaria, and joins the right bank of the Danube at Passau, after a course of over 300 miles.

Inn and Innkeeper. In Great Britain inns are houses where travelers are furnished, for the profit of the provider, with everything they have occasion for while on their journey, and may be set up without license by any person, provided he refrains from selling excisable liquors, which of course require a license. Hotels, public-houses, taverns, victualing-houses, and coffee-houses are all inns when the keepers of them make it their business to furnish travelers with food and lodging; otherwise they are not. In the United States there are no inns, but hotels in cities and taverns in rural districts. See HOTELS IN AMERICA; TAVERNS.

Innate Ideas, certain notions or conceptions declared by many philosophers to be given to the mind of man when he first receives conscious being. Their existence has been much disputed by philosophers. The term innate, as applied to ideas, was first used by Descartes. As his definition failed in precision, the doctrine of Descartes was assailed by Hobbes and Locke. As afterward more strictly stated by himself, his views were as follows: An innate idea is not one that presents itself always to our thought, for there could be no such idea; but we have within ourselves the faculty of producing it. He has nowhere given an enumeration of the ideas that he considers innate, though he attaches particular importance to that of infinity, which he makes the foundation of his proofs for

the existence of God. What the followers of Descartes designate innate ideas, those of Cousin term universal, necessary and absolute. Some of the greatest names in European philosophy are associated with the discussion of this theory, or of cognate theories, as Clarke, Newton, Malebranche, Kant, etc.

Innes, In'ës, Alexander Taylor, Scottish jurist: b. Tain, Ross and Cromarty, Scotland, 18 Dec. 1833. He was educated at Edinburgh University, was admitted to the Scottish bar in 1870, appointed advocate-depute in Scotland in 1881, and served under later Liberal governments. Among his works are: 'The Law of Creeds in Scotland' (1867); 'Church and State: A Historical Handbook' (1890); 'Studies in Scottish History' (1892); a life of Knox in the 'Famous Scots' series (1896); 'The Trial of Jesus Christ' (1899); and 'The Law of Creeds' (1902).

Inness, George, American painter: b. Newburg, N. Y., 1 May 1825; d. Bridge of Allan, Scotland, 3 Aug. 1894. His art education began in boyhood and when 16 years of age he learned map engraving. He first attempted nature sketching in 1843, when he showed such promise that he was admitted into the studio of Regis Gignoux, New York; but soon opened a studio for himself and through the liberality of a patron was enabled to visit Europe. After spending 15 months in Italy and one year (1850) in France he finally made his home at Eagleswood, near Perth Amboy, N. J. He is looked upon as the first among American landscape painters, and was not only a clever and imaginative interpreter of the scenery among which he lived, but a man of intellect, a thoughtful yet bold theorist on art subjects and an incisive critic. He had a keen appreciation of American scenery, and the sky and atmosphere of the eastern States were sympathetically portrayed with an earnestness that recalls the sentiment of the Fontainebleau-Barbizon school. His early paintings are distinguished by conscientious care for detail, vivid perception of color, and the panoramic breadth of a bold and unconventional originality. After 1878 his style had ripened, and his technique grew simpler and less highly elaborated. He was willing to sacrifice all cleverness of touch in handling detail for the sake of portraying the emotion, or transitory effect of light and cloud in a landscape, the perturbation of storm or wind, the pageant of sunset, or the magic calm of a moonlight scene. In such productions his command of color was very remarkable. His pictures are much prized by connoisseurs, and when offered for sale command high prices. Five of them are in the Metropolitan Museum of Art, New York. Among the finest are: 'Under the Greenwood'; 'Close of a Stormy Day'; 'Pine Groves of Barberini Villa'; 'An Autumn Morning'; 'Autumn Gold'; 'The Edge of the Forest'; 'Passing Storm'; 'Moonrise'; 'Winter Morning, Montclair, New Jersey.'

Inness, George, Jr., American painter: b. Paris, France, 5 Jan. 1854. He is the son of George Inness (q.v.), the landscape painter. He was a pupil of the elder Inness at Rome in 1870-4, of Bonnat at Paris in 1875, began to exhibit at the National Academy in 1877, and became a member of the National Academy of

INNOCENCE—INNOCENT

Design in 1899. In 1899 he obtained a gold medal at the Paris Salon. His manner is forcible, and skilful in color. His work includes landscapes and animal subjects, among them: 'The Pride of the Dairy' (1878); 'Pasture at Chemung'; 'A Mild Day' (1887); and 'Morning on the River' (1902).

In'nocence. A wildflower. See HOUSTONIA.

In'nocent, the name of thirteen popes, as follows:

Innocent I. **Saint:** b. Albano; d. 12 March 417. He succeeded Anastasius I. as Bishop of Rome in 402. He supported Saint Chrysostom (q.v.) when the latter was driven from his see of Constantinople through the machinations of the Empress Eudoxia. Rome was pillaged by Alaric in 410, during his pontificate. He is commemorated by the Roman Catholic Church on 28 July.

Innocent II. (**GREGORIO DE' PAPI**, or **PAPARESCHI**, grā-gō-rē'ō dā pā-pē pā-pā-rē-kē): b. Rome; d. 23 Sept. 1143. He was elected pope in 1130 by a part of the cardinals, while the others elected Peter of Leon, who took the name of Anacletus. Innocent fled to France, where he was acknowledged by the Council of Etampes, by Louis VI, and soon after by Henry II. of England; also by the Emperor Lothaire, who conducted him in 1133 to Rome, where he occupied the Lateran, while Anacletus occupied the Castle of Crescentius, the Church of St. Peter, and a large part of the city and maintained himself against Innocent until his death in 1138. He held the second Ecumenical Council in the Lateran, which condemned Arnold of Brescia and his heresy, declared all the decrees of Anacletus null, and excommunicated Roger of Sicily, who had supported the latter. Roger, however, obliged Innocent to acknowledge him as king, absolve him from excommunication, and invest him and his heirs with Apulia, Calabria, and Capua.

Innocent III. (**GIOVANNI LOTHARIO CONTI**, jō-van'nē lō tha'rē ö kōn'tē): b. Anagni, Italy, 1161; d. Perugia, Italy, 16 July 1216. On the death of Celestine III. (1198) he was unanimously elected at the age of 37. Innocent, in the vigor of manhood, endowed by nature with all the talents of a ruler, possessed of an erudition uncommon at that time, and favored by circumstances, was better qualified than any of his predecessors to elevate the Papal power. By his clemency and prudence he gained over the inhabitants of Rome, obliged the imperial prefect to take the oath of allegiance to him, and directed his attention to every quarter where he believed that a Papal claim of property or of feudal rights existed. He concluded treaties with many cities of Tuscany for the mutual protection of their liberties and those of the Church, and soon obtained possession of the ecclesiastical states in their widest extent. He excommunicated Philip Augustus, king of France; laid the kingdom under an interdict in 1200 because Philip had repudiated his wife Ingeburga, and obliged the king to submit. He was still more decided in his treatment of John, king of England, who refused to confirm the election of Stephen Langton as Archbishop of Canterbury. Innocent laid the kingdom under an interdict, and in 1212 formally deposed him. John was finally obliged to sub-

mit, resigned his territories to Rome, and received them as a Papal fief from Innocent. All Christendom acknowledged the Pope's spiritual sovereignty; two Crusades were undertaken at his order, and his influence extended even to Constantinople. Innocent was one of the greatest Popes and rulers. It has been said of his rule, as of that of Gregory VII., whom he most resembles, that in those times the power of the Pope was salutary as a bond of union for Europe, in which the still firmer bond of a common civilization and knowledge did not, as at present, exist. In 1215 he held a council, the fourth Lateran and twelfth general which passed the decree making confession and communion obligatory at Paschal time. Frederick II. was acknowledged as German emperor, and the Franciscan and Dominican orders were confirmed.

Innocent IV. (**SENIBALDI DI FIESCHI**, sā-nē-bāl'dē dē fē ēs kē): d. Naples 7 Dec. 1254. He became Pope in 1243 and was perpetually at feud with the German emperor Frederick and his successors.

Innocent V. (**PETRO DI TARENTASIA**, pē-ä'trō dē tā-rēn-tā'sē-ä): b. 1225; d. Rome 22 June 1276. His pontificate lasted only from 20 January to 22 June of the year 1276.

Innocent VI. (**ETIENNE D'ALBERT**, ä-tē-ĕn däl bär'): b. Brissac, France; d. 12 Sept. 1362. His pontificate extended from 1352 to 1362, and during this period the Papal residence was at Avignon.

Innocent VII. (**COSMO DE' MIGLIORATI**, kōs'mō dā mē-glō-rē-ătē'): b. Sulmona, Abruzzi, Italy, 1366; d. Rome 6 Nov. 1406. He was Pope from 1404 till his death, but was opposed by the antipope, Benedict XIII., who held his court at Avignon.

Innocent VIII. (**GIOVANNI BATTISTA CIBO**, jō-van'nē bät-tēs'ta chē'bō): b. Genoa 1432; d. 25 July 1492. He became Pope in 1484 and was for some time at war with Ferdinand of Naples and held the sultan Bajazet's brother Zelim a prisoner.

Innocent IX. (**GIOVANNI ANTONIO FACCHINETTI**, jō-van'nē än-tō-nē'ō fā-chē-nēt'ē): b. Bologna, Italy, 1519; d. 30 Dec. 1591. He occupied the papal chair only from the 29th of October preceding his death.

Innocent X. (**GIOVANNI BATTISTA PAMFILI**, jō-van'nē bät-tēs'tā pām-fē'lē): b. Rome 7 May 1574; d. 6 Jan. 1655. In 1629 he was elevated to the cardinalate and became Pope in 1644. Under him the temporal and spiritual power of the papacy was greatly increased. In 1651 he condemned the Treaty of Westphalia and he formally condemned Jansenism in 1653.

Innocent XI. (**BENEDETTO ODESCALCHI**, bā-nā-dēt'tō ä-dēs-kāl'kē): b. Como, Italy, 1611; d. 12 Aug. 1689. He served in his youth as a soldier in Germany and Poland, took orders later and rose through many important posts, until he was elected Pope in 1676, on the death of Clement X. He was eminent for his probity and austerity; zealously opposed nepotism and simony, and restrained luxury and excess. He condemned the New Testament of Mons and several other Jansenistic works. He also anathematized sixty-five propositions drawn from the works of modern Casuists and condemned

INNOCENT — INO

Molinos and the Quietists. He determined to abolish the right of asylum exercised in Rome by foreign ambassadors; but Louis XIV. would not yield to so just a claim, occupied Avignon, and imprisoned the papal nuncio in France; in consequence of which the authority of the Pope received a severe blow by the IV. Propositions Cleri Gallicani in 1682. These disputes were highly favorable to the English Revolution, as it induced the Pope in 1689 to unite with the allies against James II., in order to lower the influence of Louis XIV.

Innocent XII. (ANTONIO PIGNATELLI, än-tō-né'ō pēn-yā-tē'lē): b. Naples 13 March 1655; d. 27 Sept. 1700. He became archbishop of Naples, a cardinal in 1681, and Pope in 1692. During his pontificate Louis XIV. and the French bishops revoked the Declaration of the French clergy, and submitted to the judgment of the Holy See in the matters in dispute during the pontificate of Innocent XI.

Innocent XIII. (MICHELANGELO CONTI, mē-kēl-än'jē-lō kōn'tē): b. Rome 15 May 1655; d. 7 March 1724. In 1695 he was made archbishop of Tarsus, and became a cardinal in 1707. He was also made bishop of Viterbo in 1712 and succeeded Clement XI. in the papal chair in 1721.

Innocents, Feast of Holy, variously styled Innocent's Day and Childermas, a festival generally observed on the 28th, but in the Eastern Church on 29 December, in commemoration of the massacre of the children at Bethlehem, "from two years old and under," by the order of Herod, with the purpose of destroying among them the infant Saviour. The Church of England at the Reformation retained it in its ritual among its anniversary festivals. St. Cyprian refers to these children as martyrs, as does St. Augustine with still greater explicitness. It is to them that the hymn of Prudentius, 'Salvete Flores Martyrum,' is addressed.

Innocents Abroad, The, a famous book of travels by Samuel L. Clemens ("Mark Twain"). In a vein of highly original humor this widely-read book records a pleasure excursion to Europe, the Holy Land, and Egypt, in the sixties. Descriptions of real events and the peoples and lands visited are enlivened by more or less fictitious dialogue and adventures.

In'novators, a name applied in Great Britain to educational reformers who, in the 19th century, succeeded in having corporal punishment abolished in public and private schools. The novels of Charles Dickens, particularly 'Nicholas Nickleby,' and 'Oliver Twist,' had much to do with the origin of the reform movement.

Inns of Court are certain societies in Great Britain exclusively invested with the right to call to the bar. The colleges of the English professors and students of common law are called inns, the old English word for the houses of noblemen, bishops, and others of extraordinary note, being of the same significance as the French *hôtel*. The opinion is, that societies of lawyers, which before the Conquest held their chief abodes for study in ecclesiastical houses, began to be collected into permanent residences, soon after the court of common pleas was directed to be held in a fixed place,—a stipulation which occurs in the great charters

both of King John and Henry III. In these houses exercises were performed, lectures read, and degrees conferred. The inns of court are governed by masters, benchers, stewards, and other officers, and have public halls for dining, readings, etc. In London the four inns of court are: the Inner Temple and Middle Temple (formerly the dwelling of the Knights Templars, and purchased by some professors of law more than three centuries since); Lincoln's Inn and Gray's Inn (anciently belonging to the Earls of Lincoln and Gray). Each inn is self-governing, and all have equal privileges.

Innsbruck, īns'brook, or **Innspruck** (ancient *CENIPONTUM*; locally called *SCHFRUCK*), Austrian town and capital of the Tyrol, beautifully situated 59 miles north of Munich, on the banks of the Inn, near the confluence of the Sill, and almost in the centre of the valley of the Inn (Innthal), the sides of which are enclosed by mountains several miles distant, but so lofty (7,000 to 8,500 feet) as apparently almost to overhang the town. It consists of the town proper, situated on the right bank of the river, and of five suburbs. It is for the most part well built. The houses are generally of a limestone breccia, and from four to five stories high, and built in the Italian style. The buildings most deserving of notice are the Hofkirche, containing the tomb of the Emperor Maximilian I., one of the most splendid monuments of the kind in Europe, though he himself is not interred in it; and the tomb of Hofer; the Church of St. James, with a painting by Lucas Cranach; the Jesuits' church, considered the handsomest in the town; the Capuchin church, with good paintings; the new palace, built by Maria Theresa, a very extensive edifice, with gardens which stretch along the side of the Inn, and form an excellent promenade; the old palace, in which the Archdukes of Tyrol and several of the German emperors used to reside; the university, founded in 1677, and re-established in 1826, well endowed, provided with a library, botanical garden, and cabinet of natural history, and attended by about 1,000 students; a gymnasium, and several other important educational establishments; and the museum, called Ferdinandeum, rich in all the productions both of art and nature within the limits of the Tyrol. The manufactures include woolen, silk, and cotton tissues, gloves, glass, etc. As the capital of the Tyrol, Innsbruck is the place of assemblage for its states, and the seat of superior appeal, civil, and criminal courts, and of many important public offices. Many of the spots in the immediate vicinity have become memorable for the noble exploits which the Tyrolese peasantry performed in the war of Independence. Pop. (1890) 23,325.

Innuits, in'u-its. See ESKIMOS.

I'no, daughter of Cadmus and Harmonia, second wife of Athamas, king of Thebes, drew upon herself the anger of Hera by nursing Dionysus, the son by Zeus of her sister Semele. In order to favor her own children she projected the murder of her stepchildren, Phryxus and Helle, who saved themselves by flight. Hera, still more highly incensed, made Athamas, the husband of Ino, mad, and he dashed his eldest son by Ino, against a rock. Ino fled with

INOCARPUS—INQUISITION

her youngest son, Melicertes, and threw herself with him into the sea. Ino and Melicertes were made sea deities at the prayer of Dionysus. Ino was worshipped under the name of Leucothea.

Inocarpus, i-nō-kär'pūs, a genus of leguminous plants, having unifoliate leaves and yellow flowers in axillary spikes. *I. edulis* is the South Sea chestnut, native of Tahiti. It is a large tree, with luxuriant foliage, the delicate evergreen leaves being six inches or more in length. It furnishes seeds or nuts much valued in the South Sea Islands, the inhabitants gathering them while green, and mashing them for food.

Inocula'tion See INFECTION; VACCINATION.

In'osit ($C_6H_{12}O_6$), (from Greek *is*, *inos*, a nerve, a muscle), a saccharine substance found in the muscular tissues of the heart, as well as liver, brain, kidneys, etc. It appears both in health and, to an abnormal amount, in disease. It exists also in a number of plants, such as fox-glove, potato, kidney-bean, acacia, asparagus, cabbage. See GLUCOSE

Inouye Kaoru, ka-o'ru e-nō-o'yā, Count, Japanese statesman: b. in Choshū 1839, pupil of Yoshida Shoin. With Ito (q.v.), in 1862, he went secretly to Europe, and returning in 1864 became an unwavering exponent in Japan of the ideas lying at the root of Western civilization. Surviving the wounds made by reactionary assassins, he has, since 1868, served his country in various high positions, as the mikado's minister at home and as envoy abroad, especially in Korea. As minister of the interior he began the rebuilding of Tokyo from wood to brick. His famous memorial of 1873 called for moral improvement. For seven years, as head of the foreign office, he was active in treaty revision. He was created a peer in 1885, and again called to the office as minister of the interior in 1892, and retains the emperor's confidence as one of the surviving "elder statesmen," whose word in Japan is law. See KATSURA.

Inquiline, in'kwī-lin, a term applied in zoology to animals which live as tenants within the nests or homes of other animals. The use of the term is almost entirely confined to entomology and then often restricted to the cases in which the rightful and the intruding tenants are closely related. Similar cases among other animals are commonly designated as commensalism (q.v.), but these and similar terms are used rather loosely. Examples of the inquiline relation occur among the termites, ants, and bees, but are known especially among the gall-flies (*Cynipidae*); indeed, one entire division, comprising more than 500 species, is named *Inquiline*, because of the predominance of this mode of life. These insects differ but little in structure from the true gall-flies, but they lack the power to produce galls and consequently deposit their eggs within those of other species. They infest certain species of galls, as those of the blackberry and some oak-galls, in large numbers and sometimes more than one kind occur in a single gall. Perhaps the most remarkable feature of these inquilines is their frequent close resemblance to the insect which produces the gall which they infest.

Inquisi'tion, a tribunal or system of tribunals instituted by the Roman Catholic Church

for the discovery, examination, and conviction of heretics and their punishment by the secular arm. Under the successors of Constantine in the Roman Empire the repression of heresy, or rather the enforcement of the decrees of church councils and synods, was a function of the imperial government, which inflicted temporal penalties upon the propagators of religious beliefs that contradicted the creeds approved by the State. When the reigning emperor was a favorer of Arianism or any other of the heterodox creeds, the orthodox bishops and their flocks were persecuted: when he was of the orthodox party the heterodox sects were put under the ban. In executing the decrees of the councils the imperial officials, called in the laws of Theodosius and Justinian "inquisitors" (*inquisitores*), were assisted by the bishops; but the tribunals were the ordinary secular courts, and judgment was rendered in the name of the State, not the Church. But in the 12th century, when the supremacy of the ecclesiastical power was universally recognized in western Europe, the initiative in the work of repressing heresy was taken by the Church as of course, and the discovery, trial and conviction of the offenders were functions of the ecclesiastical power solely: the secular power simply executed the judgments of the church tribunals. Boniface VIII.'s definition of the respective powers and the mutual relations of church and state was not proclaimed till the close of the 13th century; but had a similar definition been promulgated in the 12th century it would have expressed the universal sentiment of princes and peoples at the time. The celebrated bull, *Unam Sanctam*, defines that "Both swords, the spiritual and the temporal, are in the power of the Church; yet the one is to be wielded for the Church's behoof, but the other by the Church herself: the one by the hand of the priest, the other by that of the king and the soldier, though at the will and sufferance of the priest *ad iutum et patientiam sacerdotis*. And sword must be subordinate to sword—*oporet gladium esse sub gladio*, and the temporal authority subject to the spiritual power—*temporalem auctoritatem spirituali subjici potestati*."

The first step toward the establishment of courts of inquisition would seem to have been taken in 1179 when the third council of the Lateran issued a decree of excommunication against the adherents of the heretical sects of southern France, who are charged not only with holding abominable heretical tenets but also with practising "unheard-of cruelties against the Catholics," demolishing the churches and massacring widows and orphans. The council grants "an indulgence of two years to those who shall make war on them." This decree was re-enforced by the Council of Verona (1184) over which Pope Lucius III. presided, and at which the Emperor Frederic I. assisted: the Council directs the bishops to bring to trial persons accused of heresy and to inflict fit punishment on the guilty. The fourth Council of the Lateran (1215), held in the reign of Innocent III., imposed on the bishops the duty of making a visitation of their dioceses twice or at least once a year either personally or by delegates to see that the Church's laws be enforced. Bishops are authorized to bind the

INSANE ASYLUMS—INSANITY

inhabitants of a district by oath to search out heretics and bring them to trial. By the Council of Toulouse (1229) in the pontificate of Gregory IX, the search for heretics (*inquisitio hereticae pravitatis*) was systematized. The bishops are to name for each parish two or three respectable laymen who shall take oath zealously to search out heretics and to deliver them up to the *baillis*. Whosoever knowingly conceals a heretic loses all his goods. If heretics are discovered on the estate of a land-owner, he incurs the penalties: the house of the heretic shall be torn down. Heretics who recant have to seek a new abode, and must wear on their clothing two crosses of different colors until the Pope or his legate permits them to assume the ordinary garb. Whoever abstains from use of the sacraments is held suspect of heresy. A person convicted or suspect of heresy is debarred from the practice of medicine. Lest the ordinary church authorities should be remiss in carrying out this system Gregory IX. named (1232) as "pontifical inquisitors" monks or friars from outside, chiefly Dominicans; shortly after the pontifical inquisitors were chosen from the order of the Dominicans exclusively. Thus the duty of inquisition was taken out of the hands of the bishops and was discharged by officials responsible only to the Pope; from the judgments of the inquisitorial tribunals there was no appeal but only to the Holy See: in 1263 Urban IV. appointed an inquisitor-general for Provence, as a means of lowering the flood of appeals to Rome. The institution passed from southern France into the other provinces of that kingdom and into Italy, Germany and Poland. The Inquisition in England was directed by the metropolitans and their suffragans without being responsible to any inquisitor-general: but as long as Lollardism disturbed the peace of the Church the search for heretics was prosecuted rigorously: bishops and archdeacons were required twice a year to make inquisition of suspects: any man might be compelled under penalties to inform against persons suspected of heresy; the statute *de haeretico comburendo* was enacted by the Parliament in 1396.

In Spain the Inquisition, as set up in 1481 by Ferdinand and Isabella, was as much (or more) a political as an ecclesiastical institution: the officials from highest to lowest were appointed by the sovereigns and its action was directed by them without responsibility to the Holy See: Ranke calls the Spanish Inquisition "a royal tribunal furnished with spiritual weapons"; Llorente admits as much. The number of persons put to death under sentence of the Inquisition in Spain is put by Llorente at 31,000 from first to last, that is during 330 years. But Llorente made it impossible to check his statements by burning the original documents. Ranke impeaches his honesty; Prescott says that his estimates are "most improbable." Catholic historians call attention to the fact that not only heresy, but many other offenses against the laws were judged by the courts of inquisition in Spain, *viz.*: polygamy, seduction, unnatural crimes, smuggling, witchcraft, sorcery, false personation, etc. At the time when the Inquisition flourished, persecution for heresy was a universal practice amongst all Christian peoples, and the methods of punishment inflicted were

general throughout Europe. Protestant England persecuted as harshly and vigorously as Catholic Spain, and in both countries denial of the state religion was equivalent to treason.

Insane Asylums, Cottage System, or Village Plan. A form of construction for insane asylums and charitable institutions, much in vogue at the present time, in which large and imposing buildings are replaced by detached cottages. The cottages vary in size from those which will accommodate six to a dozen patients to larger ones which will accommodate 20 or more. They are usually constructed either in groups or along streets and avenues as a village. In the former, the several groups are given up to a particular industry as a farm group, where the patients are employed at farming, and others, as the garden, the brick yard, shop industries, etc., all of these being a part of one institution on a single large estate. In the village plan the institution is laid off in streets and avenues, and has the appearance of an ordinary village, each cottage having a flower garden in front, shade trees, etc. In either plan, there is conveniently located near the centre of the plant an administration building, a hospital for the sick and those requiring special care, a bakery, a laundry, and other utility buildings. The cottages may be constructed of wood or other material, and the cost of construction is small as compared with the old plan of asylum construction. It is, besides, more homelike, more convenient for administration and permits of indefinite expansion. Some of the best known institutions constructed on this plan are Alt-Scherbitz near Leipzig; Gambersee near Munich, Germany; the Saint Lawrence State Hospital at Ogdensburg, N. Y., and the Craig Colony for Epileptics at Soneyea, N. Y.

Insanity, a disease of the brain characterized by disorder or derangement of the mental faculties. This is its strictly pathological or scientific definition. Therefore, according to this definition, any disease of, or accident to, the brain whatsoever, provided such disease or accident caused any derangement of the mental faculties, howsoever trifling or temporary, would furnish an example of insanity. Thus a blow on the head causing unconsciousness, or a fever giving rise to delirium, is an example of an affection of the brain characterized by disorder of the mental faculties. Practically, however, the term insanity is limited to a group of afflictions of the brain which is more distinctly fixed, and the members of which it will be the object of this brief sketch to define.

Causes.—The causes of insanity are many and various, and the chief of these are the following: Heredity, infection, poisoning, traumatism or injury, overwork or exhaustion, and mental and moral shock or strain. Of importance also are age, sex, race, and nationality.

Of all these causes the most important undoubtedly is heredity. As Krafft-Ebing, the German alienist, has well said, there is no ground, except in tuberculosis, upon which heredity shows itself more distinctly than in the case of mental disease. Statistics have been compiled by various authors to show as nearly as possible the exact prevalence of heredity in insanity, but the results have not been altogether in harmony. In fact, it is extremely difficult to determine this factor in many cases

INSANITY

in which it has been active, and this is so for two reasons: in the first place many patients and their friends conceal or deny a hereditary taint, and in the second place not a few patients and their friends, are really ignorant of their family histories beyond a generation or two. How many persons can tell accurately of what their grandparents died? The more this subject of heredity in insanity is investigated the more reason there is to believe that its importance has been underestimated rather than the reverse. And yet as a factor in causation it is much more common in some forms of insanity than in others—a fact which will be emphasized later in this article. Some authorities have limited heredity to the direct line of descent, ignoring collateral lines; but obviously this restriction cannot be maintained. And yet, if the attempt is made to trace a neurotic taint through collateral lines, the difficulty is greatly increased. The subject is vastly broadened, and, from the medico-legal standpoint, the inquiry becomes greatly involved. In mental heredity, moreover, it is not so much the particular disease that is passed on from parent to offspring, as it is the predisposition; and this predisposition, often called neurotic, is not the result entirely of insanity in the ancestry, but may be shown by a family history of other grave nervous disorders, such as epilepsy, hysteria, neurasthenia, and imbecility. This is a fact not sufficiently apprehended by the laity.

Infections of various kinds may act as causes of insanity. The most important of these is syphilis, and this acts especially to cause that form of insanity known as general paresis. The various infectious diseases, such as typhoid fever, septicæmia, smallpox, cerebro-spinal meningitis and, in minor degree, some others, may cause mental alienation. Post-febrile insanity may follow typhoid fever; and puerperal insanity may be due in part to a septic infection.

Poisons of various kinds may be very active causes of insanity. Chronic lead poisoning may give rise to a well-known form of delirium or mania; so in minor degree may mercury. But the most potent and most common of all poisons in the etiology of mental disease is undoubtedly alcohol. And this poison acts in two ways, for it may not only induce insanity in the individual, but it also is most active in causing that hereditary predisposition to insanity in the offspring to which reference has already been made. In fact, the subject of heredity is not a little involved with the subject of alcoholism in the progenitor.

Traumatism, or injury, may act as an exciting cause of insanity. This is true especially of injuries to the head. Trauma acts most readily in conjunction with other causes, such as alcoholism and syphilis. Injuries to other parts of the body, especially when associated with great shock, as in severe railroad accidents, may lead to various forms of mental alienation.

Overwork and exhaustion from any causes whatever may predispose to, or directly cause, a mental breakdown. This is true especially in cases in which the blood is depleted, the nutrition of the nervous system impaired, and the mind harassed with care and anxiety. These causes are most active in persons otherwise predisposed, as by alcoholism, syphilis or heredity.

Mental and moral shock and strain, such as

sudden loss, grief, fright, mortification, intense religious and political excitement (as in the French Revolution), long continued anxiety, and the harassment of uncongenial surroundings, as in the home-life, may all act as causes of insanity.

The above are the chief categories of causes, but they do not exhaust the subject. It is in fact too extended for brief treatment. Finally, it must be borne in mind that in any individual case not one but a combination of several of the above causes has usually been active.

Classification.—Almost every alienist of repute has attempted a classification of the forms of insanity. The subject is one of peculiar difficulty, owing largely to the fact that our intimate knowledge of many of these various forms is far from complete. One of the most satisfactory schemes is the one by Krafft-Ebing, and is as follows, slightly abridged:

"A."

MENTAL DISEASES OF THE DEVELOPED BRAIN.

I. Diseases without Anatomical Lesions, or Functional Diseases.

(1) Psychoneuroses, or diseases of a brain otherwise sound.

1st. Melancholia.

a. Simple Melancholia.

b. Stuporous Melancholia.

c. Mania.

a. Maniacal Exaltation.

b. Frenzy.

c. Stupor, or Acute Dementia.

d. Hallucinatory Delirium.

Note.—The above affections are primarily curable, but the worst of them may terminate in chronic incurable forms and in dementia.

(2) Degenerative Insanities: Affections of a brain endowed with a morbid predisposition.

1st. Constitutional Affective Insanity.

a. Paranoia.

b. Congenital.

b. Acquired. This form includes various sub-groups according to the character of the delusions entertained by the patient.

c. Periodical Insanity.

d. Mental Affections arising from the constitutional neuroses.

a. Neurasthenical.

b. Epileptic.

c. Hysterical.

d. Hypochondriacal.

II. Organic Insanities or Mental Diseases with Recognizable Lesions in the Brain.

1st. Acute Delirium.

ad. General Paresis.

3d. Cerebral Syphilis.

4th. Senile Dementia.

Note.—Chronic Alcoholic Insanity and Morphinism may yet have to be added to this group.

"B."

MENTAL AFFECTIONS OF THE UNDEVELOPED BRAIN.

Idiocy and Imbecility.

This scheme by Krafft-Ebing, while not without defects, is excellent for practical purposes and until someone can devise a better. Its great merit is that it is flexible: it readily admits new forms. Its defect is that it draws too sharp a distinction between the so-called functional and the organic insanities; and between the psychoneuroses and the constitutional forms. The truth is, all insanities are organic; and a constitutional taint may be present in the psychoneuroses.

Following this classification we note the following forms of insanity:

A. The whole group of insanities as distinct from idiocy is included under this head, and as a first great subdivision comes:

I. Mental Diseases without recognizable anatomical lesions: Functional Diseases. As

INSANITY

was inferred above, this whole group is only tentative in one sense, because as scientific knowledge advances it is found more and more that insanity in all its forms depends upon anatomical changes. For the present, however, this group may be allowed, with some reservation, to contain the following:

(1) THE PSYCHONEUROSES. In these forms the mental disease is such as can happen in a person with an otherwise perfectly normal brain. It is in a sense fortuitous, and not dependent necessarily upon a hereditary taint. Given the same causes, and it may be presumed that any person might develop a psychoneurosis, just as he might develop a fever. By this it is not implied, however, that heredity cannot act to predispose to these forms.

Melancholia is marked by depression. The affective or emotional, rather than the intellectual, faculties are involved. The patient has a sense of personal unworthiness; in other words, the depression centres about the patient's ego. He is not so much concerned about his misfortunes or his troubles, as about his unworthiness. Neither is he concerned about other persons: he is entirely self-centred. This may be said to be the keynote of melancholia. Delusions of a depressive character, as of having committed the unpardonable sin, may be present. The depression may become so profound and overwhelming that the patient passes into a stuporous or atonic state. (*Melancholia Attonita*.) In this state the physical functions, such as appetite, digestion, and nutrition, may be correspondingly depressed. Suicide may result. In some cases the patient is restless under the burden of his mental suffering (*Melancholia Agitata*).

Mania is marked by exaltation. The intellectual faculties are much more involved than in melancholia, and the patient is active, loquacious, sometimes destructive and combative, or else gay. He is somewhat incoherent, and his delusions are not well-defined, but fleeting and changeable in accord with his varying moods and disordered thoughts. The physical functions suffer as a result of exhaustion from overactivity. *Frenzy* is only a higher degree of mania, in which the mental functions are in entire disorder from over-excitation. Exhaustion is rapid.

Stupor, as its name indicates, is a psychosis in which the predominant tone is one of profound subversion of all the mental functions. *Acute Dementia* is another term for it. The patient may recover from a most unpromising state, especially in the case of young persons. *Dementia Praecox* is such a form, although the prognosis is not always good. *Primary Dementia* occurs without preceding acute stages.

Hallucinatory Delirium is a form of acute insanity marked by confusion and by the presence of hallucinations of sight and hearing. *Confusional* insanity is a term sometimes used, especially for the types which occur after acute infection, such as post-febrile insanity, and some forms following child-birth.

All these psychoneuroses may, in unfavorable cases, pass into chronic forms, and terminate in incurable dementia.

(2) THE DEGENERATIVE INSANITIES.

In these forms mental deterioration is engrafted on a constitutional defect. Heredity plays a great part. The patients have been born

with the neurotic predisposition. Their insanity is simply a logical evolution of a badly organized nervous system.

The great type of this form of insanity is *Paranoia*. The chief characteristic is the formation of systematized delusions. At first these may be of a persecutory tinge: the patient believes that he has enemies, who plot against his welfare or his life. He has hallucinations, especially of hearing. In a second stage, the delusions acquire a more expansive type: the patient believes that he is some great personage. As preliminary to all this, there is often a long career of moral and mental perversion: the patient has been noted as erratic, eccentric, visionary, and even immoral. He usually has displayed but little real brain power or steadiness, but often an intense egotism and a lack of common sense. Innumerable varieties and several stages occur. From this class are recruited in large part the criminal insane. These patients are the monomaniacs of the older writers, and they include also the moral lunatics, pyromaniacs and kleptomaniacs of more recent systematists. Among them are found also the victims of obsessions, morbid impulses and fixed ideas. The paranoiacs are the dangerous lunatics, and the prognosis is not favorable.

Periodical Insanity is a form of constitutional insanity in which, as the name indicates, there is a tendency to recurrence. This recurrence is sometimes in cycles (*Circular Insanity*), in which there is a period of maniacal exaltation, followed by one of melancholic depression, and then a somewhat prolonged period of apparent recovery, to be followed again by the morbid cycle. With every recurring cycle, however, the patient deteriorates somewhat, and may eventually degenerate into chronic insanity.

In the constitutional nervous diseases, such as Epilepsy, Hysteria, Hypochondria, and Neurasthenia, there are often mental changes of a morbid type, and these give rise to the forms of insanity named in accord with these respective neuroses. The symptoms vary widely in the several diseases.

II. In the organic insanities, so-called, the disease is marked by recognizable changes in the brain-structure.

Acute Delirium, or Bell's mania, is an acute infectious disease of the brain, of unknown origin, and of rapid progress, usually terminating fatally. It is marked by confusion and delirium, passing into coma and death. The changes in the brain are of an inflammatory kind.

General Paresis, or *Dementia Paralytica*, is caused by a progressive infectious or destructive process in the brain substance. Its dependence on syphilis is no doubt close, and it is further induced by alcoholism, dissipation and over-work. It is marked by change of character, erratic conduct and loss of mental and moral control, passing on into a stage of expansive delusions with progressive dementia. There are also characteristic speech defects, changes in the ocular muscles and in the gait, with increasing feebleness and paralysis. Various crises occur, such as maniacal, epileptoid and apoplectic, and in the last stage the patient is paralyzed and demented. Death is the inevitable result in the vast majority of cases.

In *Cerebral Syphilis* there is a characteristic inflammatory process beginning in the coats of the small blood-vessels. Mental symptoms oc-

INSCRIPTIONS

cur in great variety, also many forms of paralysis.

Senile Dementia is a form of deterioration occurring in old age, and is dependent primarily on changes in the blood-vessels in the brain. Progressive failure of mental powers, with occasional delusions, is the chief feature. In some cases paralytic and epileptic crises occur.

B. Finally we have the great group in which the mental affections are the results of arrest of development of the brain. These are not included in insanity proper by systematic writers, but are regarded as a group apart. This group includes Imbecility and Idiocy, and is defined under the latter head.

No attempt has been made in the above classification to include various debatable forms. Among such forms are *Hebephrenia* (occurring in adolescence) and *Katatonio* (a psychoneurosis with both melancholic and confusional symptoms), and some others about which alienists are not yet agreed. The list must still remain open.

PATHOLOGY.—In the group of organic insanities it has been pointed out that these diseases rest upon a recognizable anatomical basis: thus in general paresis the structural changes in the blood-vessels and tissues of the brain are so marked and so well studied that this disease may be said to have as well known a morbid anatomy as pneumonia. But this is true of very few of the insanities, and the above classification is constructed largely on the distinction between forms of insanity with, and those without, well-defined anatomical changes. But while such changes cannot in many cases be detected even with the most powerful microscope, there is practically no doubt in the minds of most alienists that all insanities depend upon a physical or structural basis. In other words, they are but manifestations of morbid changes in the brain-cells. To detect these changes is still one of the great problems of psychiatry. The tendency of modern pathology is to seek for the anatomical changes of insanity mainly in two directions: first, in heredity; and, second, in infection or toxæmia. Heredity makes its impressions so invisibly upon the brain-cell that there may be wise doubts whether we shall ever be able to detect them; but its signs, or stigmata, on the body at large are not so difficult to distinguish. The main difficulty is to interpret them. By these stigmata are meant defects or peculiarities in the grosser parts of the body, as in the bones, especially of the head and face, the ears, eyes, teeth, etc. As to infection, and the marks of it as found in the brain-cells, the evidence accumulates more and more that in many forms of insanity, especially those called functional, the direct agent is often a poison circulating in the blood and interfering with the nutrition and functioning of the brain plasma. Syphilis and chronic alcoholic poisoning leave definite changes in the blood-vessels, tissues, and membranes of the brain.

Treatment.—The treatment of insanity resolves itself into the preventive and the curative. Modern practice is beginning to concern itself more and more with the former, while of course it does not in any way relax its attention to the latter. The prodromal, or initiative, symptoms of many forms of insanity, especially the psychoneuroses, are now so well understood, that

it is often an easy matter to recognize the insidious changes that herald a mental breakdown, and to guard the patient from the dangers and misfortunes of a fully developed attack. Of first importance is to remove the patient from the exciting causes. Complete rest and isolation are therefore required and cannot be instituted too early. In order to secure these, hospital treatment is often essential. Very recently it has been proposed to treat these patients in general hospitals, in special wards, and not to hurry them into asylums under legal certification. In other words, they are to be regarded simply as other sick persons, and not to be immured merely as lunatics. The motive is thoroughly humane, and the practice is often successful in promising and selected cases. The indications are for rest, isolation and attention to the nutrition especially. There is no specific for insanity except in cases in which syphilis is active.

In very many cases, however, the nature and course of the disease render it imperative to commit the patient to special hospitals for the insane. This is not only for the good of the patient, but also for the welfare of society. These hospitals or asylums in all civilized countries are now among the very best of public institutions, and the prejudices once existing against them are no longer warranted. The indications for treatment vary according to the nature of the case. The weak and exhausted must be built up; the depressed must be encouraged and diverted; the violent and excited must be restrained; the chronic and demented must be cared for often as though they were children. The practice of to-day is in favor of all humane methods, such as by recreation, useful employment, amusements, and an appeal to the best remaining or active elements of the mental life. Physical restraint is reduced to a minimum, although in the most violent cases it cannot be entirely abolished. Punishment is practically abandoned. It is satisfactory to know that all our best regulated hospitals for the insane are enabled to report annually a good percentage of recoveries, and this is in accord with the teaching and practice of modern science, which regards insanity entirely from its physical aspect as a disease of the brain. With this definition this brief article may end as it began.

JAMES HENDRIE LLOYD,
Formerly Neurologist Philadelphia Hospital.

Inscriptions, records, engraved on stone, metal or clay. Inscriptions are in many cases the sole sources of our knowledge of ancient history and languages; and, even when MSS. are extant, inscriptions, which preserve the original

INSECT POWDER — INSECTICIDE

forms of the letters, are of supreme paleographical importance. All the books of the Phoenicians, Etruscans, Oscans, Umbrians, Babylonians, Assyrians, Numidians, and Iberians have perished, and our knowledge of early Oriental history is derived solely from inscriptions. More than 150,000 inscriptions are known. The chief classes are Semitic, Greek, Latin, Runic, Cuneiform, Egyptian, and Indian.

In Greenland, on the shores of Baffin Bay and Davis Strait, true Runic inscriptions have been discovered. They were doubtless executed by Icelandic colonists or explorers. Records once supposed to be Runic, Punic, Celtiberic, or Numidian, have also been found in the United States, as on the Dighton Rock in Massachusetts, in the island of Monhegan off the coast of Maine, in the Grave Creek Mound in West Virginia. They are, however, either natural markings on the rock, or the records of Indian tribes, or even inscriptions of early colonists. The numerous inscriptions on the walls of the palaces and temples in the ruined cities of Yucatan, Honduras, Mexico, and Guatemala are written in characters, which constitute a system of hieroglyphic or pictorial writing, akin probably to that of the Aztec MSS. which have as yet proved undecipherable.

Insect Powder, the powdered heads of certain species of chrysanthemums of the genus *Pyrethrum* whose flowers contain a volatile oil which kills insects by asphyxiation. An Asiatic species (*P. roseum*) is used in the Old World for making the insectfuge powders called pyrethrum, Persian, Dalmatian or buhach. Substantially the same thing is manufactured in California where another species (*P. cinerariaefolium*) is grown in extensive crops, and the sun-dried heads, gathered in May and June, are ground between millstones, bolted and hermetically sealed in cans. These species are also grown as garden chrysanthemums, are eaten, after drying, by live-stock, and the powder has no evil effect upon the larger animals or man.

Insecticide, any agent which destroys insects. This definition includes natural as well as artificial means of control, the latter being those operated by man. The most important of the former are adverse temperatures, excessive or insufficient moisture, fire, bacteria, fungi, mites, spiders, fish, reptiles, insects, and birds. The artificial controls may be grouped according to their mode of action. Two principal groups are recognized; those intended to reach the alimentary tract through which they act, and those that act through the respiratory apparatus. The former are effective only with such insects as bite off and swallow pieces of plant tissue; the latter more or less also with these, but most frequently used upon insects which suck the plant juices from beneath the punctured epidermis. Caterpillars, beetles and their larvæ, grasshoppers, etc., all chew their food and have been most effectively controlled by Paris green, hellebore, arsenate of lead, etc., applied to the infested foliage either as a spray or as a powder. Plant-lice, plant-bugs, and other sucking insects have been held in check best by kerosene emulsion, whale-oil soap, fir-tree oil, or other substances that choke the breathing-pores in the insects' bodies. Some of these insects are dreaded because of their great prolificacy, their

small size and resistance to treatment. Gases are often used under favorable circumstances to reach insects troublesome in stored grain, among clothes, upon plants in greenhouses, and even upon plants in the open air—these last being covered with tents or boxes while being fumigated. Various chewing insects which tunnel through the tissues cannot be controlled by sprays, and are usually beyond the reach of gases. The leaf-miners, which burrow just beneath the epidermis of leaves and green stems, have never been effectively controlled. Some borers (currant-borer) can be kept in check by burning the twigs they infest, (peach-borer) by prodding them in their burrows, (squash-vine-borer), by cutting them out, the method being suggested by the nature of attack. Other chewing insects (plum curculio) are jarred into kerosene. Lastly there are various oils and greases which are used upon animals and man to destroy fleas, lice, etc. Tobacco water and carbolic acid are also similarly employed.

Formulae and Methods of Application.—Paris green should be mixed with a little water to form a creamy fluid, and then added to water or Bordeaux mixture (see FUNGICIDE) at the rate of one pound to 200 gallons or more. Arsenate of lead may be applied somewhat more liberally. Hellebore may be mixed with water (1 ounce to 3 gallons) and a little glue or flour paste to increase adhesiveness. Each of these may be applied as a powder sifted on the plant, through a salt sack or blown upon them through a powder-gun. A little flour aids the sticking quality. When powders are used, the plants should still be wet with dew or rain. Kerosene emulsion is made by intimately mixing a solution of hard soap (one pound to two gallons of hot water) with four gallons of kerosene, and diluting as needed for use with from 30 to 60 gallons of water. Pure kerosene and crude petroleum can be safely applied only to dormant plants, and then only upon bright breezy days, which will hasten evaporation. Kero-water pumps mix kerosene and water drawn from separate tanks, and apply the mixture direct to plants. They have hardly passed the experimental stage. Whale oil soap is mixed with water (1 pound to 1 or up to 10 gallons), and applied as a wash or spray. Carbon disulphide may be used where there is no danger of its inflammable fumes coming in contact with flame. An ounce is sufficient for from 50 to 75 cubic feet of air-tight space; and the exposure should be for 24 hours or longer. Hydrocyanic acid gas is prepared by adding cyanide of potassium (98-99 per cent pure) to water and sulphuric acid (cyanide, 1 ounce; water $2\frac{1}{4}$ ounces; acid, $1\frac{1}{2}$ ounces for every 250 cubic feet of greenhouse; 100 cubic feet of nursery stock-room and 125 feet of dwelling house rooms, flour-mills, trees, etc.). Exposures may be from 30 to 60 minutes for trees, the former time being for plants in active growth, the latter for dormant ones; from 12 to 24 hours is usual for rooms, granaries, etc. Since these gases are considered violent poisons the greatest care should be exercised in their application. Oils and greases are merely rubbed on infested animals and man. Boiling water is effective in destroying both lice and eggs in clothing, but the clothing must be boiled for hours to destroy the eggs of the body-louse and the crab-louse. Dust, tobacco-dust, etc., are useful in poultry

INSECTIVORA — INSECTS

yards for the birds to wallow in. Carbolic soap is the favorite remedy for insects on pet animals. But with all stock, poultry, pets and man, cleanliness is the great preventive.

Department of Agriculture, 1891; Marlatt, 'Important Insecticides,' Farmers' Bulletin No. 127, U. S. Department of Agriculture; Hinds, 'Carbon Disulphid as an Insecticide,' Farmers' Bulletin 145 (as above); Johnson, 'Fumigation Methods' (New York, 1902).

M. G. KAINS,
Horticulturist.

Insectivora, an order of mammals, all of small size, usually five-toed, more or less plantigrade, and as a rule, possessing clavicles. "The snout is generally long, and is often prolonged into a small proboscis. There is a tendency for the teeth to be of a generalized type and their number is often the typical mammalian 44. Moreover, trituberculate teeth, which are certainly of an ancient form, are common." These teeth are adapted to feed on worms and insects alone. Many other evidences go to show that the type is a very old one, and Beddard thinks it may have survived because of the small size, imitative adaptiveness and nocturnal habits. Woodward speaks of the group as probably the little-altered survivors of some of the most primitive placental mammals, agreeing with the *Credonta* in their low type of brain. Most of the families may be traced back to the upper Eocene. The order falls into two divisions, (1) True Insectivores, including the hedgehogs (*Erinaceidae*), squirrel-shrews (*Tupaiidae*), tanrecs (*Centetidae*) otter-shrews (*Potamalidae*), huntas (*Solenodontidae*), golden moles (*Chrysochloridae*), elephant-shrews (*Macroscelidae*), aquatic moles (*Talpidae*), shrews (*Soricidae*); and (2) Dermaptera, embracing only the colugos (*Galeopithecidæ*). See HEDGEHOG; MOLE.

Insectivorous Plants. See CARNIVOROUS PLANTS.

Insects (Lat. *insectum*), a class of *Arthropoda* characterized by the body being divided into three regions, that is, a head, thorax, and hind-body or abdomen, and by the presence, in all but the more primitive and certain degraded forms, of wings, and of three pairs of thoracic legs. The body of insects consists of 21 segments (somites) of which six are used together to form the head, while there are three thoracic, and from 10 to 12 abdominal segments. To the head are appended five pairs of jointed appendages, that is, the antennæ, mandibles, and two pairs of maxillæ, while in the embryo of certain insects and in the adult *Campodea*, there has been detected a pair of vestigial appendages. Besides these appendages, there are two compound eyes, one on each side, and usually three simple eyes (ocelli) situated in the middle of the head. While the antennæ are undivided the first maxillæ are subdivided into three branches, an inner (lacinia), a middle (galea), and outer (palpifer), bearing the palpus. The second maxillæ are fused together, forming the under lip or labium; each second maxilla is composed of a lacinia, the palpus, while vestiges of the galea occur in certain forms. In bees certain accessory appendages called paraglossae are present. Besides the maxillæ, the so-called tongue or hypo-

pharynx is present, being highly developed in bees; it lies on the under side of the mouth, just above the labium; in caterpillars it receives the end of the salivary duct, and is called the spinneret. Attention should also be called to the upper lip or labium, on the under side of which is the epipharynx, which bears minute taste-pits. The thorax consists of three segments, which can be easily distinguished in the primitive wingless forms (*Campodea*) and in the cockroach and locust, but in the more specialized forms as beetles, moths, bees and flies, the segments are more or less fused together and, owing to the movements of the wing muscles, are subdivided into many separate pieces. In the wasps and bees the basal abdominal segment becomes toward the pupa state transferred to the thorax. The legs as a rule end in five jointed tarsi, the last joint bearing a pair of claws with a cushion (pulvilli) between them. Insects are enabled to walk on glass, etc., by means of a sticky fluid exuded from the ends of hollow hairs fringing the cushion. They climb by means of their claws.

Insects differ from all other animals except birds and bats in possessing wings, and their presence, especially that of the muscles of flight, have greatly modified the shape and structure of the thorax. The front pair of wings is attached to the middle thoracic segment (mesothorax) and the hind wings to the metathorax. In the two-winged flies (*Diptera*), the second pair of wings are reduced and modified to form the balancers (halteres). The wings are flat sac-like outgrowths of the skin, and are strengthened by the "veins" which form hollow rods. These veins contain a trachea, so that there is a space between the air-tube and the outer wall. When the insect emerges from the nymph or the pupa, the vein is filled with blood. The spaces enclosed by the veins and their cross-branches are called cells, and their shape often affords valuable generic and specific characters. In the more primitive insects there are numerous cross-veins, and such wings as in locusts, etc., are said to be net-veined. In the *Lepidoptera* there are few cross-veins. In the *Diptera* and *Hymenoptera* the number of veins is limited, the cells also being few. The skin of insects is hard, dense and elastic, due to the deposition of chitin.

Internal Anatomy.—One of the distinctive characteristics of insects is their mode of respiration. This is effected by an intricate system of internal air-tubes (tracheæ), which are filled with air by openings (spiracles) in the sides of the body; of these spiracles there are from one to two pairs in the thorax, and eight pairs in the abdomen. The tracheæ are kept permanently open by a series of threads (taenidium) each of which makes from three to five turns around the thin tube; in this way the entire tracheal branch is provided with what at first was supposed to be a continuous spiral thread. The slit-like openings of the spiracles are guarded by a grate of stiff hairs to prevent the ingress of dust, etc. It should be borne in mind that no insect breathes through its mouth, but through the spiracles. Hence the efficacy of all oily or greasy substances in destroying every kind of insect in whatever stage of growth; wherever the oil touches the body a thin film spreads over it, covering the air-openings so that the insect soon dies by asphyxiation. Though

INSECTS

Insects have a delicate pulsating tubular heart, they have no arteries and veins, since the air in the tracheæ seeks the blood in the remotest parts of the body. The blood is thin and colorless. The aquatic larvæ and a very few perfect insects breathe by external tracheal gills, the spiracles being in such cases often absent. The genital opening is always situated near the end of the body, in front of the vent on the under side. Besides a complicated digestive canal, insects have urinary tubes opening into the end of the intestine.

The nervous system consists, besides the brain, of a chain of ganglia the greatest number of which is 13, but which become more or less fused in the more specialized groups, especially in the flies. The brain is remarkably complex, in accordance with the varied and complicated movements of the segmented body and jointed appendages, all capable of different kinds of motions.

Sense of Sight.—The compound or faceted eyes (*ommatidia*) are composed of numerous simple eyes called ommatidia, which vary in number from 12, in *Lepisma*, to 20,000 in the dragon-fly (*Aeschna*), and even 25,000 in a beetle (*Mordella*). Yet notwithstanding the wonderful complexity of these compound eyes, most insects are near-sighted, and perceive rather the movements of other animals than their exact outlines; the dragonfly and butterfly can see for a considerable distance. The simple eye probably only enables the insect to distinguish daylight from darkness, or at most very near objects. Insects, like bees and butterflies, have the color-sense, and prefer certain colors to others.

Sense of Smell.—Insects are chiefly guided by the sense of smell. This resides in the antennæ, in which there are microscopic pits filled with fluid; to this pit goes a fine nerve whose fibres end in staff-like sense cells. The number of these olfactory organs is in some insects enormous; thus in the European cockchafer there are 39,000 in the leaves of the male antennæ, and about 35,000 in those of the female; in a single antenna of the hornet (*Vespa crabro*) are about 13,000 to 14,000. In the cockroach the abdominal cerci or feelers also possess such pits.

Sense of Hearing.—The auditory organs of the locust are drum-like ears situated one on each side of the base of the abdomen, directly behind the first abdominal spiracle; in the green grasshopper, katydids, etc., a little auditory sac is lodged in the fore-legs (*tibiae*). It is supposed that most insects are destitute of the sense of hearing, at least auditory structures have not yet been detected; yet all sound-producing insects must have ears to hear.

Sense of Taste.—The taste organs are little pits or papillæ which resemble the olfactory organs, but which occur on the inside of the upper lips, on the epipharynx, or at the base of the proboscis and maxillæ in the bee.

The Egg and Growth of Insects.—The eggs and the fertilizing fluid of the male are produced in glands which open near the end of the body on the under side. The eggs are deposited by the female in the earth or in wood, leaves, etc., by means of the ovipositor, an apparatus composed of three pairs of hard appendages, and which in the wasps and bees form the sting. Most insects die on the approach of cold weather,

when they lay their eggs, the species being represented in the winter by the eggs alone. The eggs hatch in spring, the embryo passing through remarkable changes.

Metamorphoses.—Most insects after hatching pass through a remarkable series of changes called a metamorphosis. The small flies, moths or beetles, are not the young of large ones, but adult insects, while the most primitive insects have no marked metamorphosis, the mature locust only differing from the young in having wings; the more specialized forms, as beetles, moths, wasps, bees, and flies, pass through two stages of growth, that is, the larva and pupa, before becoming winged and sexually mature.

Larva.—The name was first given by the ancients to the caterpillar because they thought it masked the form of the perfect insect. Swammerdam supposed that the larva contained within itself "the germ of the future butterfly, enclosed in what will be the case of the pupa, which is itself included in three or more skins, one over the other, that will successively cover the larva." But the discovery by Weismann (q.v.) of the germs of the imago (imaginal disks or buds) in the larva completely changed our notions of the nature of metamorphosis (q.v.), and revolutionized our knowledge of the fundamental processes concerned in the change from larva to pupa or chrysalis, and from pupa to imago. Not only are the larvæ of each order of insects characteristic in form, so that the grub or larva of beetles is readily distinguished from the larvæ of other groups, or the maggots of flies from the footless larva of ants, wasps and bees, but within the limits of the larger orders there is a great diversity of larval forms, showing that they are the result of adaptation to their surroundings and mode of life.

The larvæ of nearly if not all the metabolous animals are probably secondary in their origin. Fritz Muller (q.v.) pointed out that this is the case with the larvæ of the higher insects. The larva of a beetle is popularly called a grub; that of a fly a maggot. The young of the more primitive insects, such as the cockroach, locust, all bugs, etc., which undergo an incomplete metamorphosis, is called a *nymph*. See LARVA.

Pupa.—The word pupa is Latin, meaning baby. Linnaeus gave it this name from its resemblance to a baby which has been swathed or bound up, as is still the custom in Southern Europe. The term pupa should be restricted to the resting, inactive stage of the holometabolous insects, that is, those with a complete metamorphosis. The typical pupa is that of a moth or a butterfly, popularly called a chrysalis. A lepidopterous pupa in which the appendages are more or less folded close to the body and soldered to the integument, was called by Linnaeus a *pupa obtecta*; and when the limbs are free, as in Neuroptera, Mecoptera, Trichoptera, and the lepidopterous genus *Micropteryx*, it is called a *pupa libera*. When the pupa is enclosed in the old larval skin, which forms a pupal covering (puparium), the pupa was said by Linnaeus to be *coarctate*. The pupa of certain Diptera, as that of the orthorophous families, is nearly as much obtected as that of the tineoid families of moths, especially as regards the appendages of the head, the legs being more as in pupæ liberae. The pupæ of Coleoptera and of Hymenoptera, though there is, apparently, no near relationship between these two orders, are much alike in shape, and,

PROTECTIVE MIMICRY AMONG INSECTS.

INSECTS AND FLOWERS—INSOLVENCY

as Chapman pertinently suggests, those of both orders are helpless from their quiescence, and hence have resorted for protection to some cocoon or shell. But it is quite otherwise with the pupæ of Lepidoptera and Diptera, which vary so much in adaptation to their surroundings, and hence afford important taxonomical and phylogenetic characters. This, as regards the Lepidoptera, was almost wholly overlooked until Chapman called attention to the subject, and showed that the pupæ had characters of their own, of the greatest service in working out the classification, and hence the phylogeny of the different lepidopterous groups. The pupæ of the Neuroptera, Coleoptera and Hymenoptera differ structurally from the imago, in the parts of the head and thorax being less differentiated. Thus in the head the limits or sutures between the epipharynx and clypeus, and the occiput and gula, are obscurely marked, while the tergal and pleural sclerites of the imago are not well differentiated until the changes occurring just before the final ecdysis. It is easy, however, to homologize the appendages of the pupæ with those of the imago of all the holometabolous orders except in the case of the obtected pupæ of the Lepidoptera (and probably of the obtected dipterous pupæ), where the cephalic appendages are soldered together.

Classification of Insects.—The number of known species of insects is from 200,000 to 300,000, but it is estimated that there are upward of a million species now living. In fact, the class of insects vastly outnumbers all other groups of animals. This is probably due to their being winged, and to their great fecundity. At present the class of insects is divided into two subclasses, that is, the (1) *Synaptera*, represented by the wingless orders Thysanura and Collembola; and (2) *Pterygota*, comprising 15 winged orders and which may be thus tabulated:

Series 1.—*Heterometabola*, with an incomplete or variable, though slight, degree of metamorphosis. No distinct larva or pupa state, the young being nymphs.

- Order 1. Dermaptera. (Earwig)
" 2. Orthoptera. (Cockroach, locust, grasshopper, stick insect.)
" 3. Platyptera. (Bird lice, *Perla*, white ant.)
" 4. Odonata. (Dragonfly)
" 5. Plectoptera. (Mayfly.)
" 6. Thysanoptera. (Thrips.)
" 7. Hemiptera. (Bugs.)

Series 2.—*Holometabola*, or with a complete metamorphosis.

- Order 8. Neuroptera. (*Corydalus*, lace-wing fly, ant-lion.)
" 9. Mecoptera. (*Panorpa*, *Boreus*)
" 10. Trichoptera. (Caddis flies.)
" 11. Coleoptera. (Beetles.)
" 12. Lepidoptera. (Moths and butterflies.)
" 13. Siphonaptera. (Flea.)
" 14. Diptera. (Mosquito, fly.)
" 15. Hymenoptera. (Saw-fly, ant, wasp, bee.)

Fossil Insects.—About 3,000 species of fossil insects have been described, of these from 200 to 300 are Palæozoic, 500 Mesozoic, and the remainder are Tertiary. The oldest fossil insect remains is the wing of a supposed bug (*Protocimex*) from the Ordovician of Sweden. The wing of a cockroach (*Paleobattina*) has been detected in the middle Silurian of Calvados, France. From the Devonian shales of St. John, N. B., nine species of primitive net-veined insects have been collected. The coal measures are characterized by cockroaches, primitive dragonflies, May-flies, and grasshopper-like forms, phasmids, etc., also occurring. All of the Palæ-

ozoic insects known are very primitive. Modern forms, those having a complete metamorphosis, begin to appear in the Triassic and Jurassic, where remains of beetles, a saw-fly, and a moth occur. Ants, bees and butterflies date from the Oligocene and Miocene Tertiary.

Bibliography.—The latest general works on insects are Carpenter's 'Insects, their Structure and Life' (London, 1899), and Sharp's 'Insects' (Vols. V. and VI. of Cambridge Natural History, 1895-9); both contain sufficient references to other works. For American insects consult: Packard's 'Text-book of Entomology' (1898), and 'Guide to the Study of Insects' (1889); Comstock's 'Manual for the Study of Insects' (1895); 'Insects and Crustaceans' (Vol. II., Standard Natural History, 1884); Howard's 'The Insect Book' (1901). The last named contains a copious bibliography, especially to the voluminous publications of the Entomological Division of the U. S. Department of Agriculture.

See FRESH-WATER INSECTS; MARINE INSECTS, and the names of groups and species, as FLIES, HYMENOPTERA, MOTHS, etc.

Insessores, in-sé-só-réz, a discarded term in Ornithology designating a group styled "perchers," which included the majority of the smaller and more familiar birds. The term has been abandoned because the group denoted by it is a purely arbitrary one.

Insidious Flower-bug. See FLOWER-BUG.

Insolvency. In a popular sense the word insolvency applies only to persons without property or means sufficient to satisfy their creditors. The legal definition embraces all who are unable to pay their debts at maturity in the ordinary course of business, even though they may possess assets exceeding their liabilities. A failure to meet overdue obligations renders a person liable to proceedings against him in a court of insolvency, in which his assets may be taken into the possession of the officers, marshaled, and distributed to his creditors. Should there be an amount in excess of what is required to pay the creditors and the expenses of administration, the balance so remaining is the property of the debtor. From a very early period in the history of civil government, laws have existed providing for proceedings by creditors against insolvent debtors, by which the debtor's property could be taken from his possession, to be held by another as a trust fund to be applied to the payment of his just debts. In case of an insufficient amount to pay all debts in full, provisions are usually made for a *pro rata* distribution. These laws have generally provided for classes of preferred debts, payments of which were to be made in full, even though such payments exhausted the entire assets. Preferred claims commonly included all claims of the government or state, and often claims for labor to a limited

INSPIRATION

amount, and claims for the necessities of life. Provisions are usually made for the exemption of certain articles to the use of the debtor, not to be included in the assets. The Constitution of the United States provides that Congress may establish uniform laws on the subject of bankruptcy throughout all the States, and the first act upon that subject was passed in 1800, since which time there has been some Federal bankruptcy law, with brief interregnum. A uniform national law upon the subject now exists. The first act of Congress upon this subject provided for proceedings by the creditors only, but in 1841 an amendment provided for voluntary proceedings by the debtor, by which he could surrender his property and obtain a discharge from all of his debts, provided he had been guilty of no fraud. In the absence of a national law on the subject of insolvency, the States all have authority to enact and enforce laws upon that subject. The Federal act now provides for voluntary proceedings by the debtor, as well as proceedings against him by the creditors, with provisions for his discharge. The various State acts have usually contained such provisions. The Federal act suspends all State insolvency laws during its continuance. See BANKRUPTCY LAWS.

Inspiration, in theology, the communication by the Holy Spirit, to writers and speakers, of a portion of the knowledge and feeling of God, in such fashion that they can be communicated to other men; especially used in relation to the Bible. On the fact of inspiration rests all attribution of divinity to the sacred writings above any others; but theories of its method and extent have necessarily changed with the advance of critical knowledge. They have never had an authoritative pronouncement even from the Church of Rome, which allows liberty of judgment on this; the Bible not holding the supreme place there as in Protestant bodies, and the latter being too divided for a credal statement on this point, by the very causes which call for one. All theories rest not only on the necessary implication of divine character in the Bible, but on two specific passages: 2 Tim. iii. 16: "All Scripture is given by the inspiration of God, and is profitable for doctrine" (Revised Version, "Every Scripture inspired of God is also profitable for teaching," which does not relinquish the claim of inspiration); and 2 Pet. i. 21, "Holy men of God spake as they were moved by the Holy Ghost" (Revised essentially the same). The Scriptures were the Old Testament.

The early Church did not generally dwell on theories of inspiration, regarding it as a passive "ecstasy" in which divine truth was communicated, but rarely going on to its effects on the inspired writings or the methods which produced them. Origen, however, the great builder of doctrinal framework, formulated an exact theory of "plenary" or entire inspiration, which preserved the writers from all faults of memory, and left no iota either incorrect or superfluous in Scripture. But others held that all believers were inspired in different degrees; as this made all believers infallible interpreters of the Scriptures, the perilous nature of such a doctrine led to the opposite one, that there was an inspired official depositary of interpretation as well as an inspired canon of writings. The mediæval schoolmen evolved the theory that

there were two kinds of inspiration in the Scriptures: direct, found where moral and doctrinal truths are directly taught; and indirect, in historical passages, whence ethical truths can only be derived by allegorical interpretation.

Regarding inspiration not as a purpose but a method, there are three explanations within the limits of orthodox Christianity: the "plenary" or verbal, the dynamic, and what may be termed the "irradiant" theories. The remaining one, which makes the inspiration only that common to all human beings — who are part of the divine mind — and having no part in any special revelation, is really not a theory of inspiration at all, as it holds that there is none; that all things are parts of the world's evolution, and the sacred writers and the Bible were evolved like the rest, though the latter is the greatest moral product of the world, and to be reverenced in the moral rank as we reverence the greatest writers and thinkers in theirs.

In the early uncritical ages of the Protestant churches, the universal and obvious theory of inspiration was the plenary. The original text of the Bible was dictated word for word by the Holy Spirit, the writers being merely penmen, or media on whom were impressed certain phrases, which must not be varied on peril of distorting the divine revelation. The words of Scripture thus transmitted are God's words, to each reader as if spoken directly to him by the Deity, and no matter to what subject they relate, be it doctrine or history, the origin of man or the duty of man. That there are different styles, corresponding to different writers, means only that God has accommodated his expressions to their natures, for his own utilities. Hence the least particle in the Scriptures is surcharged with meaning, and if anything seems in conflict with science, history, or other portions of the Bible, it arises from corruption of text, bad translation, or other change from the actual revealed language. This is the only theory with perfect logical continuity; unhappily it can only be maintained, in face of the increasing body of knowledge of texts, facts, and natural ethics, by those willing to abnegate their own right of criticism wholly in favor of their own infallible interpretation. Indeed, the chief argument for the latter is that the divine purpose would be defeated, if its intention in giving the revelation were made null by the misunderstanding of fallible human faculties.

The dynamic theory is the first step outside this bulwark enforced by the impossibility of maintaining verbal inspiration, and relegates the divine agency to an indirect function. In place of its dictating the exact phraseology and the precise facts, the writers are so filled with divine force that for all purposes of conveying the essential divine purpose, that of showing the truths of sin and danger and the path of salvation, they are a portion of the divine and incapable of error. Under this theory the writers are left a free hand, according to their own limitations and those of their age, in dealing with narrative facts or their own guesses at them; but are guided explicitly in all matters of faith and morals. In order to be received, the revelation had to be accommodated to the mental conditions of different ages; and men of each received guidance from God to present it so that it was true in relation to them, and remained so for all ages under all conditions. The war-

INSTINCT

rant of the Bible is its incomparable and super-human system of ethics, and its proof of divine origin is that evident superiority to all human devices.

The "irradiant" theory is a recent one, and a step farther from the old claim of entire divinity. In this view the record as such has no divinity, nor infallibility of any kind. There is a divine revelation, but it acts by generating moral ideas in certain great selected men, and which, once generated, are left to fight their way and take their chance like the other useful ideas of the world, and undergo disbelief and mutilation, with the certainty that according to God's purpose, truth will prevail at last. The proof of divinity in Christianity lies in the fact that its moral truths are the greatest in the world, and were original with it.

Instinct. Instinctive acts are those physiological activities in which mind or consciousness is involved. Instincts may be regarded as intermediate between simple physiological or reflex actions and acts of reason exhibited by man. Animals of a grade higher than sponges, polyps, most mollusks and other forms of a corresponding grade, have organs of sense, of perception, and in the higher vertebrates a brain and nervous system and other organs of the same type as those of man, and such animals react to something more than mere physical stimuli. We know by observation that the social insects, birds and mammals, at least those which have become domesticated, have sufficient intelligence to meet the ordinary exigencies of life, and that at times the ant, bee, beaver, elephant, dog, and ape can meet extraordinary emergencies, that is, rise with the occasion; that they may to a very limited extent be free agents; that they are not mere automata. It has been observed that the more intelligent animals are not solely guided by the physical stimuli of light, odors, etc., but that they exercise the power of choice, selecting this or that kind of food, this or that mate. Animals are subject to what we call the passions: they show anger, even when not hungry or under the domination of the reproductive instincts; their sounds express dissatisfaction or contentment. They possess memory; with its aid ants and bees find their way back to their nests.

Definitions of Instinct.—Descartes believed that animals are automata. It is popularly supposed that animals are automata, physiological machines in which have been implanted by supernatural power what we call instincts. This view is still insisted on by two excellent observers of the habits of insects, Favre and Wasmann, who claim that instincts are special innate or natural propensities, "transcending the general intelligence or experience of the creature." But of late years the impression has arisen and gained force that instincts are "innate" and "natural" because they have arisen by a natural process and have been gradually acquired and transmitted from one generation to another.

Erasmus Darwin held that instincts were the result of imitation by young animals of the actions of their parents. This view is still held by Wallace, and, as Eimer claims, the power of rapid learning has played a part in the evolution of certain instincts. Thus the fox or rat learns from its parents, and becomes more cunning or

sagacious with age and training. Lamarck practically regarded the lowest animals as automata, but in the higher animals, that is, those with a nervous system, we have instinct. "Hence, instinct in animals is an inclination which necessitates that from sensations provoked while giving rise to wants the animal is impelled to act without the participation of any thought or any act of the will." To satisfy these wants they contract different kinds of habits; these are transformed, he says, into so many propensities, from which "originate their habitual actions, and special propensities to which are given the name of instinct." He then adds that the same habits and the same instinct are perpetuated from generation to generation, "without offering any notable variation, so long as it does not suffer change in the circumstances essential to the mode of life." He thus intimates that instinct may vary, and he states that in birds and mammals instinct is variable.

Darwin does not give a formal definition of instinct, but after stating that several distinct mental actions are commonly embraced by this term, he adds that "a little dose, as Pierre Huber expresses it, of judgment or reason often comes into play, even in animals low in the scale of nature." He calls attention to the points of resemblance between instincts and habits, showing that habitual action may become inherited, whence it results that "the resemblance between what originally was a habit and an instinct becomes so close as not to be distinguished." He concludes that, by natural selection, slight modifications of instinct which are in any way useful accumulate, and thus animals have slowly and gradually acquired through successive generations, their power of acting instinctively, and that they were not suddenly or specially endowed with instincts. Herbert Spencer defines it as compound reflex action, and also as "a kind of organized memory," arguing that instinctive actions grow out of reflex, and in time pass into intelligent acts. Romanes defines instinct as "reflex action into which there is imported the element of consciousness." Lloyd Morgan also says: "It is a bit of animal automatism not necessarily involving more than the lower brain centres," but it is a bit of automatism accompanied by a consciousness in a broad sense. "The role of consciousness in a chick's pecking is to select the adequate responses, and to steady the muscular mechanism to its work." As the result of recent experiments Loeb regards instincts as inherited reflexes so purposeful and so complicated in character that nothing short of intelligence and experience could have produced them. Packard gives the following definition: "The sum of inherited reflex acts, becoming habitual and arising from blended reflex and subconscious though involuntary acts, performed at birth or through life blindly, without practice or previous experience, effort, training or thought."

Examples.—It should be understood at the outset that instincts in animals are fundamentally connected with the means of obtaining food, or with reproduction, the latter involving care for the young, as in egg-laying, the selection of a nesting place by insects and birds, the construction of the nest, and the defense of the young, and in the birds and mammals the training of the young to fly, or to hunt for prey.

Reflex acts are simply physiological responses

INSTITUTE OF FRANCE

to external physical stimuli, as muscular irritability, the different tropisms, such as response to odors, and other chemical properties, to cold, heat, etc. Many of the movements of the lowest animals, as the protozoa, sponges, polyps, worms, etc., their modes of selecting and getting food, of escaping their enemies, are scarcely more than reflex. As examples of instinctive acts are those of very young chicks. Morgan regards as instinctive in these birds the act of "pecking, walking, scratching themselves, preening their down and feathers, stretching up and flapping their wings, squatting down and dusting themselves, scattering and crouching when alarmed, uttering the danger-warning *churr*, and other sounds." Young ducks afford examples in the way they "seize and mumble their food in the bill, their aptness in swimming directly on leaving their shell, piping, and smoothing the down of their breast with their bill."

It is when we observe the complicated nesting habits of the spiders, and of the social insects such as ants, wasps, bees, as well as those of birds and the muskrat and beaver, when such striking and inexplicable forms of intelligence arise that we become perplexed how to explain them. Thus take the mode in which the honey-bee builds its cells. Is it simply mechanical, the result of several bees working together, and due to the mechanical pressure of the insects against each other during the formation of the cell? While some contend that if left alone to build a single cell, this would probably be round, others show that a solitary wasp will build its cells in very regular hexagons. It is now conceded by Darwin, Romanes, and others, that the process is not a purely mechanical one, but is "constantly under the control of intelligent purpose." It is most probable that the hexagonal-cell building instinct is the result of habits which gradually arose, and which became fixed by heredity. In birds the modifications sometimes occurring in the shape and situation of their nests show that their instincts are, owing to change of conditions, plastic, reason teaching them to modify their nests so as to adapt them to new conditions. Experience and intelligence lead to such changes. The beaver manifests in his works intelligence and reasoning capacity, both in the construction of dams, canals, and in the mode of felling trees, and in the use in certain localities of "slides." In the monkeys and apes we apparently have the nearest approach to human intelligence, judging by the instances narrated by Romanes. Were it possible to breed apes for many successive generations more light would be thrown on their psychology. Meanwhile many acts performed by the domestic animals, the horse, dog, cat, elephant and even the pig, and their susceptibility to be trained, show that they may often act intelligently, and are prompted by a low degree of reason.

Instincts Variable and Sometimes at Fault.—Lemmings in their migrations, impelled by their instincts to go ahead, will swim out into the sea and be drowned. Ants will store up beads instead of seeds, and there are many instances where instinct is at fault. Certain instincts may also by change of the environment become directed into new channels. This is illustrated by numerous cases of insects, reptiles, and mammals which have become adapted to an aquatic life. An entire new crop of habits and instincts may thus arise. The instincts of young animals,

particularly of larval forms, caterpillars, grubs and maggots, are of a different description from those of the pupa state, and more especially of the adult state. In fact, instincts are pliable, variable, and in certain cases may lapse altogether, to be replaced by a new set. Were this not the case we should have no progress in the evolution of life. The more generalized animals have vastly less intelligence than the highly specialized forms. Compare the instincts of so complex a being as the ant, or wasp, or bee, with that of the locust or bug, or the instinctive and intellectual acts of social insects, with their wonderful differentiation of the individual into workers of different castes and the normal and supplemental males and females. Such are what are called complex instincts, and they are all brought into action through the principle of the division of labor.

Do Animals Reason?—Lloyd Morgan observed that the chick rapidly profits by experience after a few practical trials; hence he concludes that intelligence is founded on experience. He allows that chicks have intelligence, this involving the association of impressions and ideas, and the power of making a choice. He then asks the question, "Do animals reason"? "Do they focus the therefore"? "Do they think the why"? Probably not. Reason is not (as animals "reason") adaptation; they do not profit by experience of actions to varying circumstances. Hence, he thinks that animals probably do not reason as man is capable of reasoning. Here might be quoted Herbert Spencer's definition: "Reason or intelligence is the faculty which is concerned in the intentional adaptation of means to an end." Finally, it is safe to assume that the higher animals, especially the domestic animals, which have been in contact with and more or less trained by man, exhibit the germs of reason, and while they cannot make inductions and deductions or predictions, their intellectual acts differ rather in degree than in kind from those of the lowest human races.

ALPHEUS S. PACKARD,
Professor of Zoology, Brown University.

Institute of France, a learned body organized after the first outbreak of the French Revolution, during which all the academies of learning and arts in France had been suppressed. It was formed by the decree of 25 Oct. 1795, to replace the Académie Française, the Académie des Sciences, and the Académie des Inscriptions et Belles-Lettres. Its object was the advancement of the arts and sciences by continual researches, by the publication of new discoveries, and by a correspondence with the most distinguished scholars of all countries, and especially by promoting such scientific and literary undertakings as would tend to the national welfare and glory. The Institute was composed of a number of members residing at Paris, and an equal number of associates in the different parts of the Republic. Each class could also choose eight learned foreigners as associates. It was at first divided into three classes, each of which was subdivided into several sections. The first class embraced the physical and mathematical sciences,

INSTITUTE OF SOCIAL SERVICE— INSTITUTIONAL CHURCH

the second the moral and historical, and the third literature and the fine arts. The number of active members, exclusive of the associates, was limited to 144. The Institute received, however, its final organization by a decree of 23 Jan. 1803. It was then divided into four classes: (1) the class of the physical and mathematical sciences, consisting of 65 members; (2) the class of the French language and literature, consisting of 40 members; (3) the class of history and ancient literature, of 40 members; (4) the class of the fine arts, with 28 members. A royal ordinance of 21 March 1816, restored the former names of the classes, so that the name of Institute was applied only to the whole body collectively. The same ordinance assigned the first rank to the Académie Française, as being the oldest; the next rank to the Académie des Inscriptions et Belles-Lettres; the third to the Académie des Sciences; and the last to the Académie des Beaux-Arts. These united academies were under the personal direction of the king, and each had an independent organization. To each academy were attached 10 honorary members, who had merely the right of being present at the meetings. In 1832 the old class of Sciences Morales et Politiques was reconstituted as a separate academy, so that there are now five academies.

The Académie Française had for its chief object the cultivation of the French language, and was charged with the composition of a French dictionary, the merits of which have been often disputed and its plan condemned. The disposal of its vacant chairs has not always been regulated by the best taste and judgment, Descartes, Pascal, Molière, La Bruyère, J. J. Rousseau, Balzac, Dumas père, Daudet, and Zola having been rejected, while in former times many a shallow court favorite was accepted.

The Académie des Inscriptions et Belles-Lettres has 40 members, 10 free academicians, and 8 foreign associates. It has 40 correspondents at home and abroad, and devotes itself chiefly to subjects of a historical nature. The most distinguished scholars, both in and out of Europe, are, or have been, connected with it. Committees of this academy superintend the erection of public monuments and the preservation of those already in existence. Works brought out under its auspices are: 'Histoire littéraire de France,' 'Recueil des Historiens de France,' and 'Corpus Inscriptionum Semiticarum.'

The Académie des Sciences has for its province the various branches of knowledge connected with the physical and mathematical sciences, natural history, medicine, etc., there being in all 11 sections. It has 66 members, 10 free academicians, and 100 correspondents. The number of foreign associates is limited to eight.

The Académie des Beaux-Arts has 40 members, 10 free academicians, 10 foreign associates, and 61 correspondents. A committee of this academy was charged with the publication of a dictionary of the fine arts.

The Académie des Sciences Morales et Politiques, has 40 members, 10 free academicians, 6 foreign associates, and 48 correspondents.

Members of the Institute of France are elected for life by ballot, and have an annual salary of 1,500 francs.

Institute of Social Service, American. See SOCIAL SERVICE.

Institutional Church, a non-creedal organization of Christians, to supplement the regular church methods and ministrations—preaching, prayer-meetings, Sunday school, and pastoral visitations—by helpful social work in the community. The moving spirit is the same as in the Y. M. C. A., University Settlement, Salvation Army, Rescue Missions, Christian Endeavor societies, etc.; but "with the emphasis on Church, not Institution." The prime object is to reannex to the church the functions which other bodies have been compelled to fill by its neglect of its duty; and strengthen it by gathering potential Christian elements which under the old system do not come to it, as well as by combining in itself all the claims to public gratitude and interest now shared between the purely ecclesiastical and the purely social institutions, or the half-way houses like the Y. M. C. A. It differs from the latter in not merely furnishing a religious atmosphere which may lead to church membership, but enrolling members at once in a real church of Christian work by absorbing the secular features of the other; in a word, to do, without vows or uniforms, what the Catholic Church has always done with its charitable functions—make them an integral portion of the church organization. Hence, it is not by itself a church in the sense of the Roman Catholic or the Methodist Church, but in a broad sense a description of any church which adds educational or social work; in general use, a title of any which throws into this work its predominant vitality. Free pews are an essential accompaniment, as the social aristocracy fostered by rented pews contradicts the basal democratic principle of institutional work; hence it is sometimes called Free Church, but preferably Open Church. The present name originated with President Tucker of Dartmouth College, who applied it to Berkeley Temple, Boston.

The movement started chiefly with the High Church element in England, modeled on the Catholic idea; it flourished for two generations in that country before reaching the United States, about 1880, and it has hardly been a vigorously spreading one here for above 15 years. Now, however, a large number of churches—Episcopal, Congregational, and Baptist in the forefront, but also Methodist, Presbyterian, Unitarian—have adopted the idea with increasing vigor, besides the work of this class always performed by the brotherhoods and sisterhoods of the Roman Catholic Church. One of the earliest of these was Plymouth Church of Indianapolis, inspired by the memory of Mr. Beecher. Notable among others are the St. Bartholomew, St. George, St. Paul, and Judson Memorial of New York, and the Tabernacle of Jersey City; Berkeley Temple, Parker Memorial, and Ruggles Street Baptist of Boston; Grace and Bethany of Philadelphia; Ninth Street of Cincinnati, Pilgrim of Cleveland; Plymouth Tabernacle of Detroit; People's of St. Paul; and the Denver Tabernacle. In 1894 the Open and Institutional Church League was organized in New York; it held several conventions in Eastern cities (1895–1901), and for three years published the 'Open Church' as its organ, but has practically lapsed, being merged in the 'National Federation of Churches and Christian Workers.' The total of its work, however, is not shown by its nominal member-

INSTRUMENTS

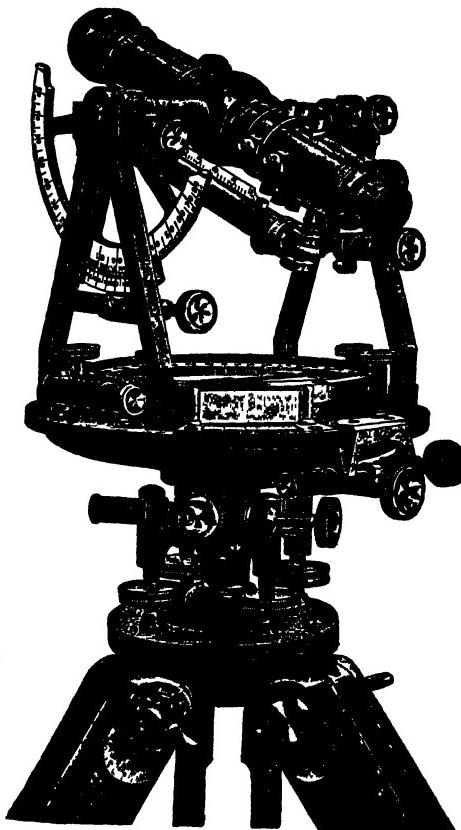

ship; the same spirit has infected outside churches, and their methods are being more and more adopted as a general basis of work.

The platform of the League stated that it aimed to save all men by "abolishing, so far as possible, the distinction between the religious and the secular"; by "open church doors for every day and all the day, free seats, a plurality of Christian workers, the personal activity of all church members, a ministry to all the community through educational, reformatory, and philanthropic channels, to the end that men may be won to Christ and his service, that the Church may be brought back to the simplicity and comprehensiveness of its primitive life." It is not correct to say, as is often done, that its methods are purely secular: its *additional* methods beyond the regular religious ones are so, for the very reason it exists. These involve a thorough organization for social and philanthropic work; but the religious features are sedulously conserved and carefully fitted to the work, the spirit of worship being cherished and made the centre of inspiration. The service generally ends in the communion; there is congregational singing of both hymns and chants, led by a highly trained choir, and often responsive readings; the whole with the sermon are intended to be brief, varied, and attractive. Sunday schools are carefully attended to; prayer meetings given new features; in summer there are open-air meetings; and other Christian associations, endeavor societies, brotherhoods, etc., are encouraged. The officers and workers of the church are given active special duties, such as pastoral visiting, reception and welcome of strangers, canvassing for the various activities of the church; and there are not only sub-pastors, but deaconesses, sisters, and nurses. The purely secular side embraces all departments of culture, physical, intellectual, and moral, as well as direct charities. Morally, the church work above should be sufficient. The charitable departments include not only direct aid to the poor, but wood-yards, employment bureaus, etc.; personal endeavor to provide employment for those willing to work; dispensaries, hospitals, and crèches; and encouragement to thrift by savings funds. Special buildings are often erected.

That the movement is liable to perversions is admitted; such is the case with every institution. Secularization is one; but unless it can be faced, the churches cannot influence or draw in those outside them, for the simple reason that the latter cannot be brought within hearing. Sensationalism, to draw in hearers to be benefited, is a graver one, and ill-judged; as one of its chief workers puts it, "a camp-stool congregation neither pays nor repents," and a lasting work must be content with slower processes.

Instruments, Engineering. To attempt a definition of an engineering instrument is hardly practicable, as the wide range of departments into which the profession is now divided demands so many special appliances for their requirements that no one description is possible, and an extended catalogue is inadmissible within the limits of this article. The earliest known engineering instrument was the Dioptra of Hero of Alexandria, 130 B.C., although rude appliances must have been used long before that time by

the ancient engineers in the construction of the public works of Chaldea and Egypt, the ruins of which even now awaken our admiration and wonder. It was not, however, until the beginning of the 19th century that the great impulse to the construction and use of engineers' instruments was given by the advance of civilization and commerce incident to the application of steam as a motive power on sea and land. Since that time great advances have been made not only in the design and accuracy of engineering instruments but also in the invention of new instruments for the many purposes required by engineers in the construction of railroads, canals, bridges, harbors, etc.

The characteristics of engineers' instruments differ in the various nations as the requirements of engineering practice, and thus American engineers' instruments possess a distinct character of their own as compared with other nations, having as a rule few parts and lightness of construction combined with great strength and an adaptability of parts for the special service required. It is not the purpose of this article to attempt a description of the various instruments used by engineers—this may be found in the article SURVEYING—but to give the reader a general idea of their construction. The metals used in the construction of engineers' instruments are principally the alloys of copper and tin with small quantities of silver, aluminum, and German silver. Great care must be constantly exercised that these substances be

INSULATOR—INSURANCE

free from iron or other material which would affect the magnetic needle. In the construction of an instrument such a distribution of the metals is aimed at that the greatest strength consistent with light weight may be obtained and that the metals coming into contact at the bearing surfaces may be of such varying composition as to cause the least friction.

Take, for the purpose of better illustration, an American transit, illustrated herewith, as typical, as far as the construction is concerned, of nearly all engineering instruments. The plate of the instrument on which the magnetic needle is mounted, or, as it is termed, the compass circle, is turned with great care so that the surface may be absolutely true, and is graduated usually into 720 spaces, each representing one half of a degree.

Compass circles are usually figured in quadrants of a circle, that is, from 0 at the point marked "N" or "North" to 90 and back again, while the figuring of the limb varies with the custom of the maker or the requirements of the engineer.

In engineers' instruments, however, the angular measurements are made usually without the use of the needle, by a telescope so mounted as to revolve in a vertical or a horizontal plane. The angular measurement of its movement being indicated on circles divided into fractional spaces of a degree and read for convenience to finer spaces by one or more verniers. Accuracy of graduation of the compass circle, and especially of the limb, is essential to the perfection of the instrument, and great pains are taken by manufacturers in perfecting and improving engines for graduating. The best machines are automatic in action and the spaces are so accurately laid off that there is no appreciable error in the finished work. The instrument rests on the socket or bearing surface to which the compass plate and limb are attached; the surfaces of the socket must be so accurately fitted together as to produce no error when the parts are moved on each other. The socket is mounted on a leveling head, which is actuated by three, or in the usual American practice, by four leveling screws, as shown, by means of which the instrument can be accurately leveled. Upon the compass plate are placed the standards which support the telescope, the preparation of the optical parts of which is next in importance to the fitting of the socket and the graduation.

The telescope consists of an eye piece and object glass mounted in a tube. The eye piece is simply a magnifier of the image produced at the focus of the object glass. Two kinds of eye pieces are used, one showing the image erect, and the other showing the image inverted. The object glass is composed of two plates of optical glass of such specific gravity and refractive index that it will magnify the image clearly without prismatic colors. To secure achromatism the two parts of the object lens are made the one of crown and the other of flint glass, the crown being a light glass of soda and silica and the flint being a heavier glass containing potash and lead. The surfaces of each are curved to such a degree that the rays of light entering the object glass may be properly refracted and concentrated at a point called the focus.

The making of the lenses is an operation

requiring much skill in manufacture, as upon the accurate grinding of the curved surfaces depends the quality of the telescope.

At the focus of the object glass are placed the cross-wires, which are filaments of spider web or very fine platinum. In conjunction with these are often used two more wires commonly called stadia wires, so placed that they intercept on a rod a space proportional to its distance from the instrument, thus furnishing an efficient method of ascertaining distances directly by the observer. The metal parts of the instrument, having been prepared, are polished with some suitable material, a preparation of rouge being generally used for finishing the surface of the screws, and the larger surfaces being finished with fine emery paper. The larger parts are usually colored dark to avoid reflection of the sun, while the smaller ones, such as screws, etc., are left bright in order that there may be a pleasing contrast between the different parts of the instrument. The parts, prepared as above, are covered with a thin coat of lacquer, a preparation of shellac and alcohol, applied after heating. All the parts are assembled and fitted together, and the instrument is then ready for the final complete adjustment. This consists in fitting the sockets so that they will move freely on each other, placing the compass plate and limb in position on the sockets, making the limb truly concentric with the socket and placing the vernier in position. The telescope must be so adjusted that its parts may work freely, and having been supplied with optical parts, etc., it is then fitted to the standards or supports previously placed in position on the compass circle. The whole instrument is then tested for accuracy and if found correct is packed in its case and is ready for use.

The above description is only intended to give a general idea of the construction of a typical instrument, but in the same methods will practically apply in the construction of all engineering instruments, such as levels, plane-tables, the various kinds of compasses, etc.

W. F. GURLEY,
of W. & L. E. Gurley, Troy, N. Y.

In'sulator, a body used to separate an electrified conductor from other bodies, and which offers great resistance to the passage of electricity. Glass, shellac, resins, sulphur, ebonite, gutta-percha, silk, and baked wood are notable insulating materials. Wires in which currents of electricity are passing are often arranged in coils. To prevent the lateral passage of electricity from one coil to another, the wires are usually covered with silk and shellac. Insulators on telegraph poles, to which the wires are attached, are usually made of porcelain, glass, or stoneware. Underground telegraph wires are usually of copper, insulated by means of a coating of gutta-percha or india-rubber, and protected by tape or iron wire, metal tubes, or wooden troughs filled with bitumen. The core of a submarine cable consists of a copper wire insulated by a covering of gutta-percha whose weight is greater than that of the wire. See *ELECTRICITY (Conductors and Insulators)*.

Insur'ance, a contract by which one party, for a stipulated consideration, undertakes to indemnify or compensate another party against loss by certain specified risks. The

INSURANCE

party undertaking to make the indemnity is usually called the insurer or underwriter, the other the insured or assured; the agreed consideration is termed the premium; the written contract, a policy; the events or causes of loss insured against, risks or perils; and the thing insured or the subject to be protected, the insurable interest. Marine insurance relates to property and risks at sea; insurance of property on shore against fire is called fire insurance; life insurance, in its widest sense, is a contract entered into by the insurer to pay a certain benefit contingent upon the duration of one or more lives. Besides these classes of insurance there are many others; the traveler may insure himself against loss entailed from damage by rail or sea; the farmer from the inroads of disease among his live stock; the employer from the fraud of a dishonest cashier, etc.

The practice of marine insurance seems to have long preceded insurances against fire and upon lives. It is impossible to state the precise period of its introduction, but it is probable that it dates from about the beginning of the 15th century; though it is contended, on the authority of certain ancient writers, that traces of this form of insurance are to be found among the Romans. Some Anglo-Saxon guilds insured their members against loss from fire, water, robbery, etc. Commercial insurance, however, seems to have originated in Flanders about 1300, although priority is claimed for both Italy and Spain. It is probable that insurance was introduced into England by the Lombards early in the 16th century, but few court cases pertaining to it are found till the middle of the 18th century.

In Great Britain fire insurance has been practised for over two centuries, but on the Continent its introduction dates considerably later. The history of life insurance, as well as that of various other forms now in practice, belongs to a still later time. For the history and development of the principal insurance systems in this country, see INSURANCE, MARINE; FIRE INSURANCE IN AMERICA; INSURANCE, LIFE, IN AMERICA; INSURANCE, FRATERNAL.

Insurance, Accident. See ACCIDENT INSURANCE.

Insurance, Casualty. The definition of the word casualty is, "chance, or what happens by chance; accident; contingency; an unfortunate chance or accident, especially one resulting in bodily injury or death," etc. The term Casualty Insurance is commonly held to include those forms of indemnity providing for payment in case of bodily injury or death, or for loss or damage to property (except from fire or the elements), resulting from accident or some other such unanticipated contingency. The four great headings into which this insurance is usually divided are Personal Accident, Liability, Steam Boiler, and Plate Glass.

Personal Accident Insurance.—The first of these to be introduced into this country was personal accident insurance which had flourished, in a limited way, for many years in Europe, but was not attempted here until 1863. The pioneer of accident insurance in America was James Goodwin Batterson of Hartford, Conn., who, while traveling in England in 1859, learned of accident tickets insuring against injuries or death resulting from railway accidents

and purchased one of these tickets in going from Leamington to London. Being at once impressed with the possibilities of developing this idea to include all forms of accidents in place of travel accidents only, he consulted with many well-known English insurance experts on the subject, all of whom with the exception of the famous statistician, Walford, expressed grave doubts as to the feasibility of the scheme. However, Mr. Batterson came home determined to make the experiment and in 1863, the first American accident insurance company was organized at Hartford, Conn. There is reliable authority for the statement that the first contract made by this company was a verbal contract entered into by the president of the company with a citizen of Hartford, whereby in consideration of a premium of 2 cents, the company agreed to become liable in the sum of \$5,000 in case of accident to the assured while journeying from the post-office to his home on Buckingham Street. The second contract was a more formal one and was issued in consideration of \$2 to protect the assured against loss of life or personal injury while journeying from Hartford to Washington, D. C., and return.

An accident policy is a contract of insurance against loss of life, limbs, sight, or time through bodily injuries effected solely by external, violent, and accidental means. The full amount of the policy is payable in case of death, or for the loss of both hands or both feet, or both eyes, or one hand and one foot. Proportionate amounts are payable for the loss of one hand or one foot or one eye, and a fixed sum is payable per week during the term of temporary disability.

The first rates, based upon the statistics of the English companies proved inapplicable to American conditions and accident insurance had a hard struggle to obtain a legitimate foothold on American soil. However, a series of catastrophes by land and sea in the following two or three years emphasized the importance of this form of protection, and little by little the business became more firmly established. During this time about 70 companies started, but all either failed or were absorbed by the pioneer company, which held the field for many years alone.

Gradually, however, other companies were organized, each newcomer profiting by the experience of its predecessors until on 1 Jan. 1904 25 stock companies were writing accident and health insurance in the United States, with aggregate premiums amounting to the enormous sum of \$13,337,000. The first accident policies were very primitive affairs compared with the elaborate and almost unlimited contracts of today. In the early times, policies covered merely loss of life, limbs, or total disability, conditions were numerous and technical, and policies for small amounts were the rule. Gradually, however, the competition of progressive and aggressive underwriters made itself felt in the broadening of the contract. One of the first important changes consisted in extending the period of weekly indemnity from 26 to 52 weeks. Some of the more conservative companies hesitated for a long time to follow this lead, but the pressure proved too great and they were finally forced to acquiesce. The policies of the leading companies have now reached the limit of liberality on this point by providing for the payment of weekly indemnity in a sum equal to the prin-

INSURANCE

cipal sum insured. One of the important innovations was the introduction of the combination policy, covering not only all of the features of the regular policy, but giving double benefits for accidents happening in or on a moving conveyance using steam, electric or cable power and provided for the use of passengers. This clause was later extended to include accidents in elevators and burning buildings, as well as in any vehicle used as a carrier of passengers, such as carriages, coaches, omnibus lines, and the like.

During this period of evolution, other changes were taking place. Conditions and agreements, that for years had been considered indispensable, began to disappear one by one. The fundamental theory that accident insurance was indemnity for loss of income, resulting from total and absolute disablement, was qualified by the broader and more flexible rule of partial disability, whereby a varying percentage of the weekly indemnity called for by the policy became payable in case the assured was not totally disabled, but was partially prevented from attending to his business duties. This payment was fixed at 50 per cent by some companies, irrespective of the nature and extent of the partial disablement, whereas other companies adopted what may seem to be a more logical basis, providing for not less than 25 per cent, nor more than 75 per cent of the weekly indemnity, depending upon the special circumstances of each case. Other important concessions were made by the elimination of conditions that had been deemed a *sine qua non* to the safe and proper conduct of the business. One of the principal of these conditions was that "injuries, of which there is no visible mark on the body, the body itself in case of death not being deemed such a mark," were not covered by the policy. Others were the exclusion of accidents from "sunstroke or freezing; from injuries intentionally inflicted upon the insured by himself or by any other person, injuries from unprovoked assault excepted; from voluntary over-exertion; violating law; violating rules of a corporation; voluntary exposure to unnecessary danger, expeditions into wild or uncivilized countries," etc. Many of these exceptions were reluctantly abandoned by the companies, often-times only after long and expensive litigation, the result of which was usually against the company.

The policies now issued by most of the companies are entirely free from all of the above-named conditions and are practically "conditionless," save as to the methods of reporting and adjusting claims. It was, however, not until 1899 that the most radical innovation yet to be introduced into the business of accident insurance was brought forward in the shape of health and disability insurance. It was perhaps but the logical sequence of events that after perfecting the accident policy to the point of the greatest liberality, the demand should make itself felt for insurance against "all the ills that human flesh is heir to" and underwriters in America again turned to their European neighbors, who had already taken the initiative. Sickness policies had become quite widely introduced into many Continental countries before that time and the system of compulsory insurance against accidents and sickness had been successfully instituted by many European governments. It is true that as early as 1847 sick-

ness insurance was attempted in America, by the organization of companies in Massachusetts and Pennsylvania, but these companies, after brief and unprofitable careers, gave up the struggle, and nothing further was attempted in this way until about the year 1896. At this time a rider to accident policies, covering about eight diseases, was adopted by one or two companies. However, the statistics available on sickness insurance did not make the business appear very attractive, and hence, during the first year or two after its general introduction into the United States, few companies were prepared to assume the risk and then only from a limited number of diseases, about 15, comprising a few of the more prevalent forms, the balance being contagious and rare diseases. Soon, however, competitors entered this field and the number of diseases covered was increased to 30, and upwards, until finally all ordinary diseases were included under the policy. At first, a health policy was not issued alone, but was combined with the accident contract, the two constituting disability insurance. Many of the leading companies still adhere to this practice; others issue the so-called unlimited health policy alone, but do not write the limited health contract, which covers a specified list of about 30 diseases, except in connection with an accident policy, while a very few companies still issue either form of health contract separately.

The introduction of disability insurance was the signal for a still further broadening of the benefits and conditions under accident contracts. The most important of these benefits are the "Schedule of Operations," providing for a fixed sum, in addition to weekly indemnity, to cover the cost of a surgical operation for any of the injuries listed in the schedule; the "Schedule of Indemnities" providing for a specified sum to be payable in lieu of weekly indemnity for any of the injuries enumerated, and the "Accumulation Table" providing for a 10 per cent increase in the principal sum insured on each annual renewal until this accumulation amounts to 50 per cent of the original sum.

A startling innovation in the year 1903 consisted in the insurance of the beneficiary, without extra charge, in addition to the policy holder. This was limited, at first, to indemnity for loss of life from travel accidents, including accidents in elevators and burning buildings. However, this was extended in 1904 to cover loss of limbs as well, from accidents above described. It is difficult to predict what limit will be reached by the companies in the eager contest for business, unless a standard policy is adopted by agreement or through legislative enactment.

The figures for 10, 20 and 30 years of premiums written and losses paid, give some astonishing results. From 1873 to 1883, premiums amounted to \$11,029,385 and losses to \$4,221,616. From 1883 to 1893, premiums were \$30,997,822 and losses \$13,904,155, or an increase of 181 per cent in business and of 229 per cent in claims. From 1893 to 1903, premiums amounted to \$64,832,874 and losses to \$28,686,686, or an increase of 109 per cent in business and of 106 per cent in losses over the previous 10-year period, and an increase of 487 per cent in premiums and of 580 per cent in losses over the first 10-year period. These figures speak eloquently of the enormous strides already made by accident insurance in America, and are but a forerunner

INSURANCE

of the growth and development that can reasonably be expected in the future.

Liability Insurance.—Liability insurance is of comparatively recent origin, and was unknown in America prior to 1887. As in the case of accident insurance, the business was first exploited in Europe, and its real development began after the passage of the English Employers' Liability Act of 1880. From time immemorial, the liability of employers for injuries caused by or suffered by their employees in the course of employment has been a part of the Common Law of all civilized nations. An eminent authority states that, as early as 1500 B.C. the Jewish law provided that "if a master were the means of causing the loss, either intentionally or unintentionally, of the eye or of the tooth of his slave, he was bound to let him go for his eye or his tooth's sake." And again, according to this same law, "if an employer allowed his ox to gore either his servant or a stranger, he was required to pay various compensations to the injured if he survived, or to his relatives in the event of the injury being followed by death."

Under the Roman law, a master was responsible not only for injuries suffered by his employees if due to his own negligence, but under the legal maxim, "*Respondeat Superior*," was liable for any personal injury sustained by a third person, due to the wrongful acts or omissions of his servants, acting as such and within the regular scope of their employment. The legal obligation to employees was expressed in the maxim, "*sic utre tuo, ut alienum non laedas*"; but the rule became subject to two important exceptions; firstly, that if the person injured and the one causing the injury were fellow-servants, the master was relieved from liability for the injury; secondly, under the doctrine of "*volenti non fit injuria*," if the person injured had actual knowledge or the means of knowing of and understanding the hazards incident to the employment and then voluntarily accepted the service, he was deemed to have assumed all the usual and ordinary dangers of the work and in case of injury, resulting therefrom, no recovery could be had against the master.

The passage of the Liability Act of 1880 by the English Parliament resulted in the organization of a number of companies for the protection of employers against the provisions of the act as well as against the expenses of litigation arising out of claims and suits instituted by employees for injuries sustained.

In 1887, the State of Massachusetts passed an Employers' Liability Act, fashioned to a great extent after the English statute, but with such changes and modifications as were necessary to suit the changed conditions.

One of the English companies then in successful operation abroad, deeming the time opportune to extend its field to America, determined to establish an American office and selected Boston, doubtless because of the existence of the act above referred to. It is stated that the local agency for the American branch was offered to various prominent insurance agents of Boston, but was declined by each in turn, as both the company and the class of business were unknown and there appeared to be no demand whatever for the kind of indemnity offered by the new-comer. It later became evident,

however, that liability insurance had come to stay, and within the next few years a number of American companies were incorporated to carry on the business, and several foreign companies established American offices on somewhat the same lines as the first company had done.

During this early period, the business was entirely experimental and rates were constantly altered to suit the changing conditions, as they arose in the development of the various features of the insurance. At the outset, the indemnity was limited to employers' liability, under substantially the following form of contract: That the company, in so far as regards fatal or non-fatal injuries to any employee or employees of the insured at the place or places mentioned in the application, during the period covered by the premium paid or by any renewal premium, would pay to the insured or his legal representatives all such sums for which the insured might become liable in damages not exceeding the limits of liability stated in the policy, such payments to be made within one week after the receipt by the company of satisfactory proofs of claim. Soon, however, the insurance was extended to public or outside liability, whereby the insured was indemnified against loss in damages on account of common law or statutory liability for personal injuries suffered by any third person and due to the business operations of the insured or of his sub-contractors. This contract was limited for some time to contractors and builders, but gradually the demand arose for similar protection on the part of owners and lessees of buildings, which resulted in the further broadening of the insurance scheme to include general liability. This contract, briefly, provided indemnity to owners or occupants of hotels, apartment houses, office buildings and wholesale and retail stores "against claims for compensation for personal injuries to any person or persons whomsoever for which the assured may be legally liable, resulting from accident (fire excepted), happening to such person or persons on or about the premises of the assured, or caused by any of the horses or vehicles of the assured used in his or their business." It was further provided, that, subject to the limits of liability expressed in the policy in respect to any accident which should cause death or injury to any one person or to several persons, "the company will pay to the assured or his legal representatives, within one week after the receipt by the company of satisfactory proofs of claim, all sums for which the assured shall become liable for personal injuries caused and limited as aforesaid, during the period covered by the premium now paid or by any renewal premium, by virtue of the common law or any statute."

It was a comparatively short step from this contract to the issuance of separate policies, covering liability for injuries caused solely by horses and vehicles, known as teams insurance, and for injuries caused by elevators, known as elevator insurance. Meantime a few of the companies were engaging quite freely in the insurance of common carriers' liability, covering "any and every accident to or caused by the cars, horses, plants, ways, works, machinery or appliances" used in the business of steam or street railroads, steamships, steamboats and ferries. It is but proper to say that this feature of liability insurance was

INSURANCE

looked on very unfavorably by the more conservative companies, and one of the companies engaging in the business notified its agency force after the disastrous results of this underwriting became first apparent in 1893 that, "we are not now seeking to push these specialties, as we find competitors (particularly companies whose managers have a commission interest), doing such business at rates which can only be productive of serious loss. Railways we take only when the lines are short, and street railways not at all in great cities." But the handwriting was already on the wall, and in November 1893 one of the largest and most important companies was forced into bankruptcy, largely through the losses sustained on common carriers' liability. This placed almost an embargo on that class of business, only two or three companies continuing to issue such policies. Two of these later discontinued the business entirely, and the other, after a somewhat meteoric career, collapsed in 1897 with heavy liabilities and few assets. In March 1896 the first significant action was taken with a view of placing liability insurance upon a sound scientific underwriting basis in the shape of a conference of the leading companies held in New York. After a series of meetings and discussions extending over a period of several weeks, an organization was effected known as the Conference of Liability Companies. A bureau of statistics was formed, with a well-known underwriter in charge, and the work of compiling the experience of the various companies was vigorously taken up. Frequent meetings of the Conference were called at which the managers and officers of the various companies discussed the different phases of the business and compared experiences. Policy forms were analyzed and conflicting conditions either eliminated or reconciled. As a result of these meetings, and of the work of the bureau, a manual of rules and rates was promulgated in the summer of 1896 and standard policy forms were adopted shortly afterwards. From time to time thereafter manuals and supplements have been issued by the Conference companies altering rates already established and publishing new rates, these changes and additions resulting from the statistical work carried on by the bureau.

Logical development of liability insurance in America dates from the formation of the liability Conference. Standard rates and policies having been adopted, competition was reduced to practically legitimate methods, and for three years the business went on smoothly and grew rapidly.

This highly satisfactory condition of affairs was rudely disturbed early in the year 1900 by the withdrawal of one of the largest companies from the agreement, and while the Conference continued in existence, its usefulness was considerably impaired. Shortly after this time three foreign companies established American offices and two additional companies were organized in this country, and as none of these newcomers became members of the Conference, the situation grew more critical than before and the companies comprising the Conference came to be the minority, while they had formerly constituted the majority. Early in 1903 one of the smaller companies in the agreement withdrew, being unable to withstand the competition of the outside companies. At

the beginning of 1904, the Conference consisted of five companies, while twelve companies were operating independently.

This great discrepancy in numbers has forced the Conference to become almost solely a bureau of statistics and there is little attempt made to the adherence of standard rates in cases of competition, which are of course the rule rather than the exception. In spite, however, of what might be termed these unsatisfactory conditions, the business has grown and developed astonishingly. From the inconspicuous beginning in 1887 already noted, liability insurance has in the comparatively short space of 17 years taken its place as one of the most important branches of underwriting in this country involving more technical and difficult features than almost any other kind of insurance business.

The liability policies of the present day are substantially the same with all companies, and are known respectively as Employers' Liability, Public Liability, General Liability, Teams Liability, Elevator Liability, Owners' Contingent Liability, Theatre Liability, and Marine Vessel Liability. The premium is based, in most cases, on the estimated annual payroll of employees, and is subject to adjustment at expiration of the policy according as the actual payroll expended is greater or less than the amount estimated. To ascertain this, the assured is required to render a payroll statement to the company which is usually verified by an audit of the assured's books.

Under the various forms of policies issued, protection against legal liability for damages on account of accidental death or injuries to employees and the public is afforded to manufacturers, and contractors, owners, lessees, and tenants of buildings; to owners and users of horses and vehicles, including automobiles, elevators, vessels and boats; to theatres, agricultural exhibitions and shows, and to owners and general contractors of buildings in course of construction. While at first the limits of liability were rarely in excess of \$5,000 for one person injured or killed and \$10,000 for two or more persons injured or killed in any one accident it is now quite common to provide double these limits and in fact the indemnity is often fixed at limits of \$10,000 for one person and \$50,000 for a number of persons injured or killed in one accident. These increased limits are due not only to the inevitable tendency of the courts in the majority of States to sustain verdicts for large amounts, but more particularly to the enactment of laws increasing and extending the liability of employers and others in cases of negligence. For example, in New York State the statutory limit for damages in case of fatal injury from negligence was \$5,000 for an individual until this limit was removed by the legislature a few years ago, leaving the amount recoverable in such cases unlimited. In Illinois, likewise, the sum of \$5,000 was formerly the maximum amount payable, but an act of 1903 increased the individual limit to \$10,000. While it was rare to read 10 years ago of a verdict for \$5,000, such amounts are now deemed quite reasonable in serious or fatal cases, and it is not unusual to find that verdicts of ten, twenty, and even fifty thousand dollars are sustained by the courts of last resort. In fact, legislation is playing a most important part in the evolution of liability insurance in this coun-

INSURANCE

try. The Employers Liability Act of 1887 of Massachusetts, while the most important statute yet to be enacted on this subject, in America, has never been quite satisfactory and just as changes and amendments have been constantly suggested for the English acts of 1880 and 1897, so the legislators of the Bay State have attempted from time to time to extend and alter the provisions of their act. The latest effort in this direction, proposed in 1904, is known as the Workingman's Compensation Act and is quite revolutionary in its character so far as this country is concerned, for nothing of the sort has ever been attempted here before. In the words of an eminent member of Congress from Massachusetts, while discussing this measure, "One of the principal reasons for it is because there have grown up in this country, lawyers and doctors who combine together to hunt up trouble and cheat the injured person out of his money. Another great trouble and reason for the proposed legislation is the employee's habit of bringing suit at once, without trying to bring about amicable relations with the employer. As things are to-day, while employers frequently have to pay out large sums of money, in many cases the injured employee is not benefited. Now, an employee has to show that he received his injuries as the result of the neglect or fault of the employer. This new law does away with all of this and favors the compensation of an employee for the loss of an arm or other serious injury, whether the employer is to blame or not." The passage of the so-called Slater Act of 1902 by New York State was another step in the direction of absolute compensation to workingmen and it is only a question of time and probably a short time, when most of the important States will have legislated on this subject. Not only so, but there is some talk of a national act to be put forward by the United States government affecting these vital questions of the relations between capital and labor.

It may not be entirely utopian to believe that the ameliorating influences of these State laws either with or without a national statute will result ultimately in the more friendly and unselfish attitude between employers and employees and in the discontinuance of strikes and labor disturbances generally.

The growth of liability insurance has kept pace with the industrial development of this country during the past 15 years as will be noted from the following exhibit: From 1889 to 1893 inclusive, premiums amounted to \$9,319,591 and losses to \$3,838,665. From 1894 to 1898 inclusive, premiums were \$20,535,668 and losses \$10,084,319, or an increase of 120 per cent in income and of 162 per cent in claims. From 1899 to 1903 inclusive, premiums were about \$50,000,000 and losses about \$25,000,000 or an increase of 250 per cent in premiums and of 250 per cent in losses over the previous five-year period, and an increase of 437 per cent in premiums and of 552 per cent in losses over the first five-year period.

Steam Boiler Insurance.—The first steam boiler insurance in America was written in 1866, dating almost as early as accident insurance, and like that other branch of indemnity, it owes its origin in this country to the thrifty, practical citizens of Connecticut. It was, however, not until 1869 that the business became well established. At the close of that year total premiums amounted to \$55,819,

and total losses to \$2,188, a modest beginning considering that for the year 1903, premiums aggregated about \$2,000,000, and losses about \$200,000, while the amount of insurance in force had grown from \$5,000,000 to over \$600,000,000.

For many years the pioneer company had a monopoly of the field, as, for some unknown reason, capitalists seemed disposed to leave this business alone, due, perhaps, to the slow growth of the premium income, as well as to the mechanical technicalities of the insurance.

At the outset, the form of contract was limited to indemnity for loss or damage to the boiler or boilers and other property of the assured, and to property of others for which the assured could be held legally liable, due to the explosion, rupture or collapse of the boiler or boilers. As a guarantee of the value of this indemnity, as well as a protection to the company against the insurance of old and unsafe boilers, a periodical inspection is made of each boiler during the term of the policy by an inspector of the company, and a written report is forwarded to the policy holder showing the condition of the boiler, recommending such repairs or changes as appear necessary, and stipulating the pressure under which the boiler can safely be run. Steam users were at first slow to grasp the many advantages offered by this new scheme, and engineers of plants strongly resented the reflection on their skill and management implied by some of the features of the insurance. Conflicts of opinion between the inspector of the company and the engineer of the assured were of frequent occurrence and oftentimes much hard feeling was engendered. Nothing daunted by these obstacles, the company vigorously pushed forward the business and at the end of the first 20 years the premium income had grown to about \$1,000,000.

In the year 1887 another company was organized which gave considerable impetus to the business and introduced a new feature, namely, indemnity against loss from legal liability for fatal or non-fatal injuries suffered by any person or persons due to the explosion, rupture, or collapse of the boiler or boilers. From this time forward the business increased rapidly.

On 1 Jan. 1904 nine companies were engaged in the business of the insurance of boilers, tanks, dryers, rotaries, digesters, and other objects operated under steam pressure. Nearly 150,000 boilers were regularly inspected in 1903 and a small army of inspectors are maintained by the various companies at an annual expenditure of several hundred thousand dollars. Policies are frequently issued for as much as \$100,000 limit for any one loss, and a limit of \$50,000 is quite common. Notwithstanding the great number of objects insured annually, and the large limits of liability as above mentioned, serious explosions have been comparatively rare, and the average loss ratio of the largest company for 35 years has not exceeded 10 per cent per year. This showing would seem to indicate that there is an exceptionally large profit to be made in this branch of casualty insurance, but such is not the case, for owing to the inspection system before mentioned, the management expenses range from 60 to 85 per cent of the premium income. Some of the companies maintain in connection with

INSURANCE

the inspection department, a force of draughtsmen for the purpose of furnishing plans and specifications for new boilers, at the request of their policy holders or of prospective clients. This service is rendered without charge and adds somewhat to the already heavy expense of conducting the business. It is interesting to learn from the statistics of one of the companies, that from the beginning of their business to 1 Jan. 1903 the number of visits of inspection made was 1,815,465. The total number of boilers inspected was 3,568,838. The total number of defects discovered was 2,559,592, of which dangerous defects numbered 270,856, and 15,169 boilers were condemned as unfit for use. During the year 1902 the company made 142,000 visits of inspection, examined 264,708 boilers, condemned 1,004 boilers, found 145,489 defects, of which 13,000 were dangerous.

The total premiums of all companies during 35 years, to the close of 1903, amounted to nearly \$25,000,000, and total losses to almost \$2,500,000, and with the rapid increase in the number of new manufacturing plants throughout the country, and the general expansion of business, it is safe to predict that steam boiler insurance will develop much more rapidly in the next decade than in the past quarter century.

Plate Glass Insurance.—The first American plate glass insurance company was organized in New Jersey in 1868, but unlike the pioneers in the other casualty lines, this company does not rank among the leading companies in point of financial strength or amount of business written. In 1874, the first New York company was started, and from that year the business steadily increased in volume, total premiums for 1903 amounting to over \$2,000,000, and total losses to over \$800,000. There have been fewer changes in the plate glass policy than in any other of the casualty contracts, presumably because the business is less intricate and there has been no occasion to make many changes. Plate glass insurance provides indemnity on account of loss or damage caused by breakage of glass, provided that such breakage is the result of accident and due to causes beyond the control of the assured. No claim is paid, however, for breakage resulting directly or indirectly from fire, earthquake, inundation, insurrection, riot, or any military or usurped power, or from the blowing up of buildings or from alterations or repairs to the premises. While for years the insurance was limited almost entirely to what is known as plain plate glass, many different kinds of glass, such as bevelled, mitred, cathedral, leaded, chipped, bent, Florentine, jewelled, ribbed and wired glass are now insured freely by all companies.

In 1900 plate glass underwriters were confronted with an entirely new proposition in the shape of clamped or patented plate glass, resulting from riveting the sides and tops of plate glass together without the use of wooden frames that before that time had been indispensable. The rates formulated for patented glass were at first entirely inadequate and the companies lost a considerable sum while experimenting with the subject. Not only was there great trouble and delay in having broken glass replaced, but the patentees, having a monopoly, were disposed to secure the full benefit from the product of their ingenuity. As a result of these conditions, the companies placed an almost prohibitive rate on

all patented glass in the hope that they could successfully taboo that kind of risk, but the public demand for it was too great and patented glass has come more and more into general use. However, near the close of the year 1903, the leading companies found that the experience with patented glass had been more favorable than had been anticipated, and, as a result, the rate was materially reduced.

Plate glass insurance is now almost as general as fire insurance, and while the average premium is small, the business has assumed very considerable proportions. During 30 years ending 31 Dec. 1903 total premiums amounted to over \$20,000,000, and total losses to over \$8,000,000. Fifteen stock companies were on that date engaged in the business, in addition to numerous local mutual companies located in various parts of the country. From time to time in the past 10 years, compacts have been formed between the largest companies for the purpose of regulating rates, and establishing sound underwriting practices. Unfortunately, however, these agreements have been of comparatively short duration and as oftentimes happens in similar cases, the demoralization following the termination of the compact has been even greater than before it was made.

It is difficult to predict what will be the final outcome of the admittedly unsatisfactory state of affairs prevailing in plate glass insurance, with rates low, commissions excessively high (sometimes as much as 50 per cent), and the cost of replacements increasing, unless the companies form a national compact and place the business upon a logical underwriting basis. One company heretofore writing plate glass insurance alone, decided early in the year 1904 to add a personal accident department, and it is probably only a question of time when every company engaged in this one line of business will be forced either to add other lines of insurance, or to consolidate with other companies engaged in the same business.

Sprinkler Leakage Insurance.—While not constituting one of the main divisions of casualty insurance, this form of policy is written to a limited extent by two of the casualty companies, as well as by some fire insurance companies. The contract covers loss or damage to the building and contents caused by the accidental discharge or leakage (except from fire) of the sprinkler equipment erected in or on the premises. The premium, based at a varying rate, depending on the class of merchandise covered, is predicated upon a certain percentage, usually 10 per cent, of the cash value of the building, stock, and machinery. Sprinkler leakage insurance has been in vogue only nine years in America, during which period the total premiums have not amounted to any considerable sum. There is, however, a slow, steady growth of the business, due to the wider use of sprinklers in mercantile and manufacturing plants, principally in the Eastern and Middle States.

Fly-wheel Insurance.—This is one of the less important branches of casualty insurance and is of recent origin in this country. One company alone is engaged in the business at this time, and hence the statistics are limited. The contract covers loss caused by the explosion, bursting, or disruption, during rotation of the fly-wheels or any of them, first for loss upon the fly-wheel or fly-wheels and upon other property

and total losses to \$2,188, a modest beginning considering that for the year 1903, premiums aggregated about \$2,000,000, and losses about \$200,000, while the amount of insurance in force had grown from \$5,000,000 to over \$600,000,000.

For many years the pioneer company had a monopoly of the field, as, for some unknown reason, capitalists seemed disposed to leave this business alone, due, perhaps, to the slow growth of the premium income, as well as to the mechanical technicalities of the insurance.

At the outset, the form of contract was limited to indemnity for loss or damage to the boiler or boilers and other property of the assured, and to property of others for which the assured could be held legally liable, due to the explosion, rupture or collapse of the boiler or boilers. As a guarantee of the value of this indemnity, as well as a protection to the company against the insurance of old and unsafe boilers, a periodical inspection is made of each boiler during the term of the policy by an inspector of the company, and a written report is forwarded to the policy holder showing the condition of the boiler, recommending such repairs or changes as appear necessary, and stipulating the pressure under which the boiler can safely be run. Steam users were at first slow to grasp the many advantages offered by this new scheme, and engineers of plants strongly resented the reflection on their skill and management implied by some of the features of the insurance. Conflicts of opinion between the inspector of the company and the engineer of the assured were of frequent occurrence and oftentimes much hard feeling was engendered. Nothing daunted by these obstacles, the company vigorously pushed forward the business and at the end of the first 20 years the premium income had grown to about \$1,000,-000.

In the year 1887 another company was organized which gave considerable impetus to the business and introduced a new feature, namely, indemnity against loss from legal liability for fatal or non-fatal injuries suffered by any person or persons due to the explosion, rupture, or collapse of the boiler or boilers. From this time forward the business increased rapidly.

On 1 Jan. 1904 nine companies were engaged in the business of the insurance of boilers, tanks, dryers, rotaries, digesters, and other objects operated under steam pressure. Nearly 150,000 boilers were regularly inspected in 1903 and a small army of inspectors are maintained by the various companies at an annual expenditure of several hundred thousand dollars. Policies are frequently issued for as much as \$100,000 limit for any one loss, and a limit of \$50,000 is quite common. Notwithstanding the great number of objects insured annually, and the large limits of liability as above mentioned, serious explosions have been comparatively rare, and the average loss ratio of the largest company for 35 years has not exceeded 10 per cent per year. This showing would seem to indicate that there is an exceptionally large profit to be made in this branch of casualty insurance, but such is not the case, for owing to the inspection system before mentioned, the management expenses range from 60 to 85 per cent of the premium income. Some of the companies maintain in connection with

INSURANCE

the inspection department, a force of draughtsmen for the purpose of furnishing plans and specifications for new boilers, at the request of their policy holders or of prospective clients. This service is rendered without charge and adds somewhat to the already heavy expense of conducting the business. It is interesting to learn from the statistics of one of the companies, that from the beginning of their business to 1 Jan. 1903 the number of visits of inspection made was 1,815,465. The total number of boilers inspected was 3,568,838. The total number of defects discovered was 2,559,592, of which dangerous defects numbered 270,856, and 15,169 boilers were condemned as unfit for use. During the year 1902 the company made 1,42,000 visits of inspection, examined 264,708 boilers, condemned 1,004 boilers, found 145,489 defects, of which 13,000 were dangerous.

The total premiums of all companies during 35 years, to the close of 1903, amounted to nearly \$25,000,000, and total losses to almost \$2,500,000, and with the rapid increase in the number of new manufacturing plants throughout the country, and the general expansion of business, it is safe to predict that steam boiler insurance will develop much more rapidly in the next decade than in the past quarter century.

Plate Glass Insurance.—The first American plate glass insurance company was organized in New Jersey in 1868, but unlike the pioneers in the other casualty lines, this company does not rank among the leading companies in point of financial strength or amount of business written. In 1874, the first New York company was started, and from that year the business steadily increased in volume, total premiums for 1903 amounting to over \$2,000,000, and total losses to over \$800,000. There have been fewer changes in the plate glass policy than in any other of the casualty contracts, presumably because the business is less intricate and there has been no occasion to make many changes. Plate glass insurance provides indemnity on account of loss or damage caused by breakage of glass, provided that such breakage is the result of accident and due to causes beyond the control of the assured. No claim is paid, however, for breakage resulting directly or indirectly from fire, earthquake, inundation, insurrection, riot, or any military or usurped power, or from the blowing up of buildings or from alterations or repairs to the premises. While for years the insurance was limited almost entirely to what is known as plain plate glass, many different kinds of glass, such as bevelled, mitred, cathedral, leaded, chipped, bent, Florentine, jewelled, ribbed and wired glass are now insured freely by all companies.

In 1900 plate glass underwriters were confronted with an entirely new proposition in the shape of clamped or patented plate glass, resulting from riveting the sides and tops of plate glass together without the use of wooden frames that before that time had been indispensable. The rates formulated for patented glass were at first entirely inadequate and the companies lost a considerable sum while experimenting with the subject. Not only was there great trouble and delay in having broken glass replaced, but the patentees, having a monopoly, were disposed to secure the full benefit from the product of their ingenuity. As a result of these conditions, the companies placed an almost prohibitive rate on

all patented glass in the hope that they could successfully taboo that kind of risk, but the public demand for it was too great and patented glass has come more and more into general use. However, near the close of the year 1903, the leading companies found that the experience with patented glass had been more favorable than had been anticipated, and, as a result, the rate was materially reduced.

Plate glass insurance is now almost as general as fire insurance, and while the average premium is small, the business has assumed very considerable proportions. During 30 years ending 31 Dec. 1903 total premiums amounted to over \$20,000,000, and total losses to over \$8,000,000. Fifteen stock companies were on that date engaged in the business, in addition to numerous local mutual companies located in various parts of the country. From time to time in the past 10 years, compacts have been formed between the largest companies for the purpose of regulating rates, and establishing sound underwriting practices. Unfortunately, however, these agreements have been of comparatively short duration and as oftentimes happens in similar cases, the demoralization following the termination of the compact has been even greater than before it was made.

It is difficult to predict what will be the final outcome of the admittedly unsatisfactory state of affairs prevailing in plate glass insurance, with rates low, commissions excessively high (sometimes as much as 50 per cent), and the cost of replacements increasing, unless the companies form a national compact and place the business upon a logical underwriting basis. One company heretofore writing plate glass insurance alone, decided early in the year 1904 to add a personal accident department, and it is probably only a question of time when every company engaged in this one line of business will be forced either to add other lines of insurance, or to consolidate with other companies engaged in the same business.

Sprinkler Leakage Insurance.—While not constituting one of the main divisions of casualty insurance, this form of policy is written to a limited extent by two of the casualty companies, as well as by some fire insurance companies. The contract covers loss or damage to the building and contents caused by the accidental discharge or leakage (except from fire) of the sprinkler equipment erected in or on the premises. The premium, based at a varying rate, depending on the class of merchandise covered, is predicated upon a certain percentage, usually 10 per cent, of the cash value of the building, stock, and machinery. Sprinkler leakage insurance has been in vogue only nine years in America, during which period the total premiums have not amounted to any considerable sum. There is, however, a slow, steady growth of the business, due to the wider use of sprinklers in mercantile and manufacturing plants, principally in the Eastern and Middle States.

Fly-wheel Insurance.—This is one of the less important branches of casualty insurance and is of recent origin in this country. One company alone is engaged in the business at this time, and hence the statistics are limited. The contract covers loss caused by the explosion, bursting, or disruption, during rotation of the fly-wheels or any of them, first for loss upon the fly-wheel or fly-wheels and upon other property

INSURANCE

of the assured; second, for loss from liability of the assured for loss upon property of any other person or persons; third, for loss from liability of the assured for bodily injuries or death sustained by any person or persons. Fly-wheel insurance is more or less allied to boiler insurance, and the limits of the company's liability in case of loss, as well as the rates of premium and the methods of handling the business, are very much the same as in boiler insurance. The insurance against breakage of machinery in general is being introduced to some extent in one or two European countries, but has not yet been attempted in America. There appears to be a field for such a policy, and doubtless the indemnity will be offered by some American company before very long. In fact, at the present time, a few corporations are engaged in the business of insuring the maintenance of electric machinery and of making the repairs found necessary from a periodical inspection of the premises or plants.

Physicians' Liability Insurance.—This is another of the modern schemes in casualty insurance, and provides indemnity against loss from common law or statutory liability for damages on account of bodily injuries fatal or non-fatal suffered by any person or persons in consequence of any alleged error, mistake, or malpractice by the assured in the practice of his profession. The limits of the company's liability are uniformly \$5,000 for one person injured or killed, and \$10,000 for any number of persons injured or killed during the term of the policy. Naturally, the moral hazard is the main consideration in a contract of this nature, and, while a fixed premium is charged, a careful selection is made by the conservative companies of the risks offered.

Taken all in all, the field for casualty insurance is an ever widening one, and the vast interests involved have given to this branch of indemnity a place in the front rank of insurance schemes. The magnitude of the business, the great scope of the contracts, the elaborate and comprehensive machinery required to properly conduct the affairs of these great corporations, can best be understood and appreciated when it is known that during the period in which the various lines of casualty insurance heretofore enumerated have been written by the total premiums have exceeded \$221,000,000, the total losses have been more than \$88,000,000, and the total amount of insurance in force on 1 Jan. 1904 was estimated at the bewildering sum of over \$5,000,000,000.

EDWIN W. DE LEON,
*Vice-President Casualty Company of America,
New York*

Insurance, Credit, is a business proposition which offers to the seller of merchandise on credit protection against excessive losses as the result of bad debts. When loss occurs a certain percentage is to be borne by the party insured, and the balance of the loss is made good by the company issuing the policy of indemnity. To illustrate: Application is made for an insurance bond on sales amounting to \$400,000 a year, and a bond is written on a basis of one half of 1 per cent loss; this one half of 1 per cent on sales, or \$2,000, would represent the insured's own risk in bad debts, and if he lost no more than that amount he would receive nothing from his in-

surance. But should his losses be \$5,000 in bad debts, his own loss would still be only \$2,000, and the excess, or \$3,000, would be paid him by the insurer, provided the losses had come within the terms and conditions of the bond. Credit insurance is a natural product of the present age. The first important systematic aid to the credit system was the establishment of the commercial agency, which is now recognized as indispensable to an intelligent transaction of credit business. But this first aid was not complete within itself, and a supplementary system was needed to still further minimize the risk of excessive losses through insolvency of debtors, which want is supplied by credit insurance.

The annual losses in the United States by the insolvency of debtors exceed by about 50 per cent the losses by fire. It has long been the general custom to pay insurance companies to carry the risk of loss by fire, but until comparatively recent years each merchant had to carry his own risk of loss through insolvency of debtors. Credit insurance is based on the sound economic principle which recognizes the province of the specialist. Both fire and life insurance offer protection superior to that which can be obtained through any other medium, because the principle of the law of average cannot be efficiently employed except by the specialist. Protection is against the possibility of abnormal loss no less with fire than with credit insurance. Credit insurance from the standpoint of the insurer proceeds on the principle of average which promises a profitable return on the sale of protection. The cost of protection is assessed on the basis of normal losses accruing in any given business for a period of years. Such loss may be termed the normal loss. Normal loss is that inevitable impairment of resource which can be borne by a business and yet admit of a satisfactory dividend on capital invested. Abnormal loss is loss in excess of that which permits satisfactory dividend on capital investment, and it is against such loss that credit insurance offers protection. From the standpoint of the insured, credit protection cannot be considered a profit-earning investment. It is simply and solely protection against excessive loss by bad debts. A crop failure; an epidemic of disease, or a widespread or protracted industrial labor strike, are possibilities of danger which no man can provide against, as respects commercial credits, except through the medium of insurance protection. Experience may qualify a credit man to guard against bad debts through the rascality or impaired credit condition of those seeking credit, but no amount of experience or capacity can of themselves render it possible to provide against contingencies growing out of such cases as above mentioned.

Great care should be exercised by the insured in taking out a policy of credit indemnity. The peculiar need of his business should be intelligently considered. Precedent cannot be safely followed, for the character of every man's business is in more or less degree individual. Unless an intelligent application of the principle of credit insurance is made to each individual case, the greatest amount of protection cannot be realized. The principle of credit insurance being economically sound, it follows that if the insured in any given case does not realize the protection contemplated, it is because the conditions of the

INSURANCE ENGINEERING — INSURANCE, FRATERNAL

indemnity are not adjusted to the needs of the business. No amount of indemnity can be considered a profit maker of itself; its true sphere is that of a profit saver. In explanation of the proposition that an insured is always a loser, when his losses make demand on the indemnity company, it is conceivable that excess losses should so dovetail with the conditions of the policy as to reimburse the insured for every dollar of excess loss, but such instances would be rare indeed.

It would be practically impossible to limit precisely the line of credit on every individual case to the exact ratio of protection. Such a conservative policy would by no means realize the best results of credit protection, and, if strictly adhered to, would restrict rather than expand business. Protection can be made to operate injuriously in both directions, and it would be as false policy to limit business to the letter of protection as it would be to expand it beyond the limits of the spirit of indemnity. A credit should not be extended merely by reason of the collateral security furnished by credit-indemnity, but such security should be used to justify a risk which would not otherwise be undertaken, and to increase a line of credit beyond its natural unsecured limit. A bank will not lend on collateral alone. The personnel of an individual borrower is an equation which can not be eliminated, whether the loan be in money by a bank or in merchandise by a merchant. Collateral security in the case of a bank operates to reduce the interest rate, and the difference between the rate which would be demanded without collateral and the rate with collateral, measures the premium paid by the bank for the protection. In the case of a merchant, the rate paid for protection is the cost of carrying the security as represented by the premium on the policy of indemnity. The banker, therefore, pays a higher rate for collateral protection than the merchant.

The essential features of the contract between the insured and the insurer are: (1) The insured to bear a normal loss of an agreed percentage of his annual sales. The said ratio of own loss to be determined by facts established by the record of the business for a series of years. (2) Insurance to apply to both rated and unrated accounts at an agreed ratio, as the circumstances of the business in question may require and justify. (3) Liberal insolvency conditions, in which technical distinctions are eliminated, and the actual and virtual facts equitably arrived at. (4) Prompt payment of losses at the period of settlement.

J. A. TAYLOR,
Prest. Wilmington, N. C., Board of Trade.

Insurance Engineering, a science or method of procedure for the better application of principles and rules in the business of insuring property against fire. The decision of the trustees of the Massachusetts Institute of Technology to establish a course in what for want of a better name has been designated insurance engineering, is commendable and should meet with hearty encouragement from the fire underwriters. Its object will be to instruct those who take the course in the selection and constructive use of materials with a view to minimize the risk of destruction by fire. Naturally, this will for the present relate more directly to mill and factory property than to dwellings, but the influence of such a school should soon be

felt in every department of architecture, especially if out of its work shall grow a determination on the part of the fire underwriters to make such discrimination against buildings in which they are expected to take all the risks as will make it to the advantage of those who build or buy houses of any kind to do what is possible to share this risk by guarding against fire within practicable limits of slow-burning construction.

The latest official calculations — those of Insurance Commissioner Dearth of Minnesota — lead to the conclusion that 75 per cent of the enormous annual loss from fires in this country results from fires which are preventable. The policy of the insurance companies has lent itself to the encouragement of indifference on the part of owners of insured property to everything except the rate of premium. Commissioner Dearth's further conclusions are:

It is not to the large number of promiscuous fires that heavy losses to property are attributable, but more to the larger select risks occurring in heavy commercial circles where great values are involved. One of the greatest evils in fire underwriting is in the matter of over-insurance, which places a premium upon criminal carelessness on the part of the assured, if not absolute incendiарism. For this evil the companies themselves alone are, of course, to blame, and consequently have it entirely within their power to eliminate. There is very little question that the companies are at the present time exercising a far greater degree of precaution in this direction than heretofore; in short, cancellations, reducing the liability of the companies on all the more hazardous classes of risks, are causing not only the local agents, but the assured, no end of trouble, and much greater care is, beyond question, being exercised in the line of inspections, especially looking to the matter of values as compared with the amount of insurance covering on the property. These are all matters that are being strenuously considered by the underwriters throughout the country, and beyond question must result in a material decrease in the fire waste.

The erection of insurance engineering into a profession will enable the insurance companies gradually to reorganize their business on safer lines, and in so doing discourage the practices which have grown up through the co-operation of owners and agents to saddle them with larger responsibilities than any scale of practicable premiums would warrant. The number of men qualified to practise as insurance engineers has never been great enough to meet the requirements of the companies. The new school should have an immediate and important practical relation to the public welfare in the safeguarding of life and property and the raising of the standards of construction in buildings admitting of classification as insurable risks.

The undertaking has the enthusiastic support and co-operation of Edward Atkinson of Boston, whose efforts in recent years have materially changed the methods of mill construction and the theories of industrial insurance; and it has appealed so strongly to mill owners, builders, manufacturers, and other investors to whom fire is a constant menace that, at Mr. Atkinson's instance, a fund sufficient to place it at once on a substantial money basis with liberal allowance for the heavy initial expense has been raised

Insurance, Fraternal. The principles which govern the system of fraternal insurance can be gleaned only from the decisions of the courts of law, the dictum of the insurance departments of the different States, the files of the leading fraternal journals, and the official reports issued by the National Fraternal Congress, the associated fraternities of America and the fraternal societies themselves.

INSURANCE, FRATERNAL

Fraternal Insurance, as popularly understood at the present time, is "The obligation of a fraternal beneficiary association to pay the benefits prescribed in its constitution and laws when all requirements by or on behalf of the members are fulfilled." In the early days of fraternalism in America the term "protection" was universally used in describing the benefits furnished by the different beneficiary societies. See FRATERNAL BENEFICIARY SOCIETIES IN AMERICA.

The term fraternal insurance, although originally a misnomer, and clearly inapplicable in any true conception of the real aims and objects of a fraternal beneficiary association, has, however, come into general use of late years as being synonymous with the words fraternal protection and fraternal benefits, whenever reference is made to the money benefits paid by a fraternal beneficiary society. This change has come about so gradually that it is difficult to trace its origin or fully measure its effects. The primary cause of this mingling of insurance terms with fraternal names has undoubtedly been the failure of the officials of the different societies to constantly keep in mind the distinction between the insurance contract supplied by an insurance company and the fraternal protection furnished by a fraternal society, while a secondary cause has been the efforts of the insurance commissioners of the different States to compel all fraternal beneficiary associations to comply with the regulations in force as to insurance companies.

In order, therefore, to fully understand the scope and meaning of the term fraternal insurance, as now understood, it is first necessary to ascertain the meaning of the word insurance. Webster defines it as "a contract whereby for a stipulated consideration called premium one party undertakes to indemnify or guarantee another against loss by certain specified risks." The supreme court of Pennsylvania (1890), in the case of the Commonwealth *v.* the Equitable Beneficial Association (137 Pa. St. 412) (18 Atl. 1,112), thus points out the distinction between regular life insurance and fraternal protection, as then understood.

"The general object or purpose of an insurance company is to afford indemnity or security against loss. Its engagement is not founded in any philanthropic, benevolent, or charitable principle; it is a purely business venture, in which one, for a stipulated consideration or premium per cent engages to make up, wholly or in part, or in a certain agreed amount, any specific loss which another may sustain, and it may apply to loss of property, to personal injury, or to loss of life. To grant indemnity or security against loss, for a consideration, is not only the design and purpose of an insurance company, but is also the dominant and characteristic feature of the contract of insurance.

"What is known as a beneficial association, however, has a wholly different object and purpose in view. The great underlying purpose of the association is not to indemnify or secure against loss; its design is to accumulate a fund from the contributions of members for beneficial or protective purposes, to be used in their own aid or relief in the misfortunes of sickness, injury or death. The benefits, although secured by contract, and for that reason, to a limited extent, assimilated to the proceeds of insurance,

are not so considered. Such societies are rather of the philanthropic or benevolent character. Their beneficial features may be of a narrow or restrictive character; the motives of the members may be to some extent selfish, but the principle upon which they rest is founded in the considerations mentioned. These benefits, by the rules of the organization, are payable to their own unfortunate out of funds which the members themselves have contributed for the purpose, not as an indemnity or security against loss, but as a protective relief in cases of sickness or injury, or to provide the means of a decent burial in the event of death. Such societies have no capital stock; they yield no profit, and their contracts, although beneficial and protective, altogether exclude the idea of insurance, or of indemnity, or of security against loss."

We may therefore assume that insurance is a contract between an insurance company on the one hand and the insured on the other, and provides for the payment of a specific indemnity by the company in consideration of certain stipulated premium payments by or on behalf of the insured. It has been held that a verbal contract of insurance is valid, but by universal practice the contract is made in writing, and is called a policy. The policy, therefore, expresses the terms of the contract, and governs the right of the parties.

Fraternal insurance, on the other hand, is the very antithesis of insurance as above understood. A fraternal society does not, and under the laws of the different States has no power to, make an insurance contract. It does not, and cannot, issue a policy. It does not promise indemnity against loss, and is not limited to any stipulated premium payments. Its contract is not between the society on the one hand and the members on the other, but between the members of the society, each with the others, and this contract is not expressed in the certificate of membership issued by the society. This certificate which it issues is not a policy. If it were, the society would immediately cease to be a fraternal society, and be not only classed by the insurance departments of the different States as an insurance company, but required to report and pay taxes as such. The usual form of certificate in use certifies that the holder has been duly and regularly accepted and admitted to membership in the organization, and entitled to all the rights and privileges accruing under the specified benefit, as prescribed in its constitution and laws as then existing or subsequently altered or amended by the duly constituted supreme body of the association. The certificate, therefore, is merely evidence of membership, and certifies that the holder is entitled to the rights and privileges flowing therefrom. It is in no sense a policy, and has never been so construed by any court of last resort.

If late years there has been some conflict in the decisions of the courts as to the legal effect of some peculiar certificates of membership that have been issued by fraternal associations, but in the leading cases the courts have uniformly adhered to the rule that the certificate is merely evidence of membership, and that the rights of the parties, or, in other words, the contract for fraternal protection, is governed by the constitution and laws of the organization as they exist at the time the right to the benefit accrued, although in some cases the society has been held

INSURANCE, LIFE

to have waived certain provisions in its constitution and laws because of peculiar features in its certificate, and in other cases, certain practices or customs that, in the judgment of the court, tended to mislead the members, as to the proper construction or binding effect of some clauses in the constitution, have been held to be a waiver on those provisions.

The laws of the different States require every fraternal beneficiary association to have a representative form of government and to be organized and carried on for the sole benefit of its members and their beneficiaries. Each member, therefore, has a voice in the management, and has no right to complain of any lawful changes, alterations or amendments to the constitution and laws made during his membership, because they have been made by him or in his behalf, and for the general good of the entire membership.

As the organization is purely mutual, every member who is to share in the benefits ought in equity to bear his fair share of the cost, and it follows, therefore, that he is also bound by any changes that may be made in his rate of dues or assessments by the constituted authorities of the organization.

To sum up in a word, "insurance" is a contract, while fraternal protection is the result of a contract; the one makes a definite promise of a certain indemnity in consideration of certain stipulated premium payments, while the other is the obligation of a fraternal association to pay the benefits prescribed in its constitution and laws when all requirements by or on behalf of a member have been fulfilled. Many, of course, prefer to rely on the business promise of the insurance company to pay the prescribed indemnity, but the millions of members in the fraternal societies of America prefer their fraternal protection, not only because it is cheaper, but because it is better and surer. Every member of every fraternal association fully realizes that any tampering with good faith in dealing with any single member would be fatal to the organization, and ultimately injure the entire membership. In the judgment of all true fraternalists, the mutual interests of the members, therefore, constitute a safeguard that is far more reliable, and certainly more durable, than the mere promise of any purely business company. The membership of the various fraternal beneficiary associations in America that report to the insurance departments of the different States is over 4,500,000, and the amount of protection carried is in excess of \$6,450,000,000. Up to the end of 1902, the various societies have distributed over \$800,000,000 among the beneficiaries of deceased members. Last year their total payments for death losses were over \$73,000,000. These figures do not include the vast number of small societies scattered through the various States which do not report to the insurance departments. For further information consult: The Annual Reports of the Insurance Departments of the different States, and the Official Reports of the Fraternal Beneficiary Societies.

FREDERICK GASTON,
President *The Grand Fraternity.*

Insurance, Life, In America. The ordinary mind fails to grasp the significance of the enormous figures representing the business of American life assurance companies at the present day. The accumulated funds of the companies

reporting to the State of New York in 1902 were over \$2,000,000,000, and the assurance in force in these same companies was over \$8,400,000,000. The existing American companies have during the past 50 years paid out, in the shape of matured policies, dividends of profits, surrender values, etc., more than \$3,000,000,000. If what is known as "industrial" business were added to the above figures, the assurance in force would be larger by over \$1,700,000,000, and assessment and fraternal assurance would add nearly \$6,500,000,000 more.

It may assist the imagination in realizing the immensity of these sums to compare the accumulations of the standard American life assurance companies with some other large masses of investments. For example, the national debt of the United States is \$1,314,929,600, or about two thirds the amount of the accumulated funds of the American life assurance companies reporting to the State of New York. The capital of the Bank of England is £14,553,000, which at \$4.86618 would be \$70,800,000, or about one fifth of the accumulated assets of any one of the three largest life assurance companies of America, and less than one twenty-fifth of the accumulated funds of all the American companies reporting to the State of New York. The combined capital of all the national and State banks in New York city is about \$199,224,700.

In support of the statement that the great sums of money and obligations accumulated by the American life assurance companies have been chiefly rolled up within 50 years, it may be stated that the entire assets of the 15 life assurance companies existing in the United States in 1852 amounted to little over \$7,900,000, and the amount assured by policies then existing hardly exceeded \$80,000,000.

The returns of these companies, as collated in the first annual report of the Insurance Commissioner of Massachusetts, made in 1855, indicate that the business of life assurance at that time was in an exceedingly crude state, both as to volume and method, and it would astonish many an agent engaged in soliciting business for companies in modern times, on the basis of large dividends of profits, to see how little in that day was made of this feature of the assurance contract, the attention of the officers being concentrated upon the elements of permanency and certainty of payment. One company says in its official report: "We disapprove of dividends, except conditional dividends, and hope to see the system abandoned." Another company answers: "Dividends annually, if the condition of the company is such as to admit of the same safely, and then declared in scrip." Another says: "Dividends paid at the discretion of directors." These admissions by the American companies in their infant stage are almost comical when compared with the modern returns, showing, for example, that during the year 1902, \$26,589,715.25 in dividends were paid to policy-holders by the companies reporting to the State of New York, and besides, \$310,917,220.77 of surplus were held for apportionment and distribution at times when future dividends fall due under the contracts.

If the tremendous results of the American companies were due to a natural and spontaneous evolution, we should expect to find a similar condition of things in other countries than the United States, but this is not the case. Life assurance was, indeed, a gradual development in

INSURANCE, LIFE

the older countries. It would be difficult to state accurately how early the principle of mutual assurance was put into some kind of practice. Ordinances are discovered in France and other continental countries as early as the 16th century prohibiting any assurance on the life of men, showing that the practice must have obtained before that time, and was then frowned upon. Modern assurance in any organized form seems to have been first adopted probably as early as the 15th century. The first English statute on this subject was passed in 1601, and recites that "it hath bene tyme out of mynde an usage amongst merchants, bothe of this realme and of forraine nacyons, when they make any greate adventure, to give some consideracion of money to other persons to have from them assurance made of their goodes." Organized fire insurance seems to have dated from the latter part of the 17th century. Annuities and tontines were also known after the middle of the 17th century, and it was in the latter part of this century that Halley, the Astronomer Royal of that day, published what is known as 'The Breslau Table of Mortality.' This was one of the earliest steps taken toward the recognition of life assurance as a science, and the study and development of the science in a practical way are indicated by the successive mortality tables, each improving on its predecessor.

The first organized life assurance institution in England was the Amicable Society, founded in 1706, but the real history of British life assurance begins with the organization of the Equitable Life Assurance Society in 1762, and Dr. Price, who repeatedly did work for that company, constructed the 'Northampton Mortality Tables' in 1780, which was long regarded as a true guide to the expectation and duration of life, and is still used by the supreme court of the State of New York as a basis for estimating the value of certain life estates. The 'Carlisle Table of Mortality' was published by Mr. Joshua Milne in 1816, from observations upon the mortality of two parishes in the city of Carlisle. The table is still in use, even among some American companies, for annuities, but has been generally supplanted by later and more appropriate tables deduced from the experience of many life assurance companies, the principal tables being the 'Actuaries,' or 'Seventeen Offices Experience,' 'The Institute of Actuaries Experience' (1863), 'The American Experience' and the new experience just published by the Institute of Actuaries, which now form the guides for American assurance organizations.

The history of life assurance in Great Britain, from the latter part of the 17th century to the present time, has been one of gradual growth. In 1867, a list was published of over 350 life assurance companies that had been organized in Great Britain. Many of these were "bubble" concerns, as may be inferred from the fact that to-day there are less than 100 British companies doing business in ordinary life assurance. The total ordinary business in force in these companies is a little over £660,000,000, or, at \$4,866,18, about \$3,211,678,800 and the accumulated funds of these companies is only a little over £296,000,000, or, at \$4,866,18, about \$1,440,389,280. Thus it appears that in what may be called the birthplace of life insurance, the accumulated funds of 125 years are about \$500,000,000 less than the American companies have

accumulated in 50 years, and the outstanding assurance of the former is less than two fifths of that of the latter.

If we pursue our investigations into Germany, we find that there are 63 companies, whose amount of assurance in force is over \$1,986,000,000, and whose total accumulated funds are more than \$867,600,000. In France there are 16 companies, whose amount of assurance in force is \$688,470,000, and their accumulated funds are over \$399,300,000.

How, then, is the enormous advantage in progress of the American companies to be accounted for? The answer is, by American enterprise and industry. There are men living who have observed the progress of life assurance in America during the last half-century who can testify to the truth of this assertion. I think it will be generally admitted that the late Henry B. Hyde, the founder of the Equitable Life Assurance Society of the United States, and afterward its president, more than any other one man injected a spirit of aggressive energy into the business. From the time that he entered the field, what had theretofore been an easy-going and sluggish conduct of life assurance affairs became an active, vigorous, competitive administration. The ingenuity of mathematicians and business men began to be taxed to devise methods in connection with assurance which would make it more popular and divest it of many onerous conditions which had grown up in the past; and the ambition of individual propagandists to extend the blessings of life assurance began to be stimulated in a way then altogether unprecedented. The method of accumulating dividends of profits for the benefit of persisting policy-holders during long periods, thus making an advantageous offset to the burden of long-continued payments of premium, became one of the features of American life assurance, and appealed naturally and successfully to the keen American mind.

It was formerly the custom, not only in Europe, but in America, for life companies to keep the widows and other beneficiaries of deceased policy-holders waiting for periods varying from 3 to 6 months after the death of the bread-winner before the money on the policy could be availed of, while lawyers searched for reasons to escape payment. In America this practice has become almost a dead letter. Companies which do not unhesitatingly pay at once upon the death of the assured cannot hold their own in competition. One company advertises every year the promptness with which its claims have been paid, showing in 1902, for example, that nearly 81 per cent of its death losses were paid within a day after the proofs of death were submitted, and more than 91 per cent of the whole within one week thereafter.

Another concession of American companies to the rights of the assured has been what is known as the "incontestable feature," by means of which the company estops itself from making any resistance to the policy on any ground whatever, except non-payment of premium, after it has been in force for one year. This has been one of the most radical, and at the same time reasonable, reforms in American life assurance. It has abolished all that narrow quibbling which too often characterized the action of life assurance companies in former times, and has placed the responsibility on the companies of

INSURANCE, MARINE

discovering frauds and mistakes within a brief period after the assurance is issued, and usually during the lifetime of the party most concerned.

Space does not admit of a further pursuit of this examination. The healthful innovations brought about by rivalry in competition have been so numerous and so important as to make the policies of American companies extremely attractive, even to those living in foreign countries, and it is a tribute to the enterprise and skill of American life underwriters that several of them have "carried the war into Africa," so to speak, and established their business in Great Britain, Germany, France, Russia, Spain, and, indeed, in all distant lands. The three largest companies of the United States have for many years been transacting business in foreign countries, and had assurance in force in these countries at the end of 1902 amounting to \$874,488.

American life assurance is on a footing as firm as that of any business in the world. There are degrees, of course, of excellence represented in the management of American companies, but taking not only the more successful but the average of the institutions, it may be confidently asserted that no safer or more carefully conducted financial enterprises exist.

The number of persons holding policies in the American companies of all kinds at the present time is probably upward of 20,000,000. Of these, say, about 1¼ per cent, or 250,000, may be taken as the number dying in a year. Taking five persons as the average number in each family, there would remain an average of four beneficiaries on the death of each person assured, or about 1,000,000 persons in 1902 benefited by the payment of about \$192,000,000 in death losses by all the companies. As a means of distributing wealth, and protecting the unfortunate at the cost of the more fortunate, nothing could be devised which would more nearly approach the ideal than the American system of life assurance. And all these figures are annually increasing.

There are probably between 40,000 and 50,000 men and women making their living as agents in propagating the business of life assurance in the United States. These industrious people are veritable missionaries for the highest good, and in these days when there is so much discussion as to the most feasible way of arresting poverty and encouraging thrift, the study of life assurance as practised in America by the companies which have worked out such an example to the world would repay the time and attention given to it on the part of every intelligent citizen who loves his country and his kind.

JAMES W. ALEXANDER,
President Equitable Life Assurance Society.

Insurance, Marine. American marine insurance business had its birth at about the close of the 18th century, but suffered heavily when the American flag began to disappear from the high seas. For the past quarter of a century it has had a hard struggle to keep itself anywhere near the old standard of prosperity. To do this it has had to draw for the greater part of its returns upon foreign commerce, and been forced to compete with English companies.

New York's marine-insurance history is that of all the other seaboard States, for in nearly all marine insurance once flourished, but has now

succumbed to English competition. The golden period of American marine insurance was between the years 1840 and 1860, when the clipper sailing ship was developed and perfected. In those times the leading merchants owned their own ships, and frequently a member of the firm would go to China or the East Indies to supervise the proper distribution of the cargo, and to secure a remunerative one for the return. The ship and cargo were insured with an American company, and as it might be as long as nine months before the vessel was heard from, the risk was considerable and rates were high. As much as five or six per cent was charged for insurance in those times. The rate on dry goods from Liverpool to New York in the old packet sailing ships was placed at two per cent. This trade was carried in American ships, and the insurance, both on the vessel and on the cargo, was naturally placed in American companies.

But the rates of insurance have changed with the transformation of the ocean-carrying service. The East India goods are now shipped across the Pacific to San Francisco, and thence east via rail. The cost of insurance on these is now only three quarters of one per cent. Rates on the Atlantic have likewise declined. Insurance on dry-goods and like merchandise carried in the modern "liners" is placed at two tenths of one per cent. In other classes of goods depreciation in rates is in like proportion.

Marine underwriters do not ascribe the decline in American marine insurance to any trouble from unwise laws or legislative interference, but to the changed business conditions and to English competition. The bulk of the carrying trade of the world has passed into British hands, and a British merchant and ship owner insures in a British company. The English marine companies have, as well, invaded American soil, and have secured a large portion of the American business. When the English companies first established themselves in America, along in the early seventies, they began cutting rates. The American companies did not effect any combination to prevent this, but followed their example. The American companies were also placed somewhat at a disadvantage by the laws governing the admission of foreign marine-insurance corporations. The foreign companies are required to make a deposit before they can write American business; but in New York State, which has stringent insurance laws, the amount is fixed at the minimum capitalization allowed a home company, namely, \$200,000. So much of the carrying trade of the world is done under the British flag and with the aid of British credit, and with countries under British control, that the American underwriter, working against all these disadvantages, is seriously handicapped. Therefore, there being no national or local tariff associations among marine underwriters, the American companies are worsted in this rate war. There are now not enough of them to form any sort of an association which would wield much power.

Despite the work of the American companies to hold their own, through loss of prestige on the ocean and active rivalry on land there are a number of stock and mutual American marine-insurance companies which continue to do a flourishing business. The largest and one of the oldest is the Atlantic Mutual of New York, which has over \$12,000,000 of assets, and has

INSURANCE PATROL — INSURRECTION

been most carefully managed throughout its career. It was formed in 1842, at the time when many stock companies were turned into mutual companies, and by which change the profits accrue to the policy-holders instead of the stockholders. The company is noted for retaining its faithful and tried officers until their death. The late John P. Jones was connected with the company for 50 years, and was its president for 40. In his life-work of building up the company he was ably assisted by vice-presidents W. H. H. Moore and A. A. Raven, who have been with the company 30 and 40 years respectively. Among the other large companies which still do a thriving business are the two Boston corporations, the China Mutual and the Boston Marine.

There have never been many marine Lloyds in the United States, though this form of marine insurance has been most in vogue in marine underwriting in Great Britain. The origin of the term is both interesting and peculiar. The name of Lloyd originated in old Lloyd's Tavern, in Tower Street, London, far back in the days of Queen Anne. It was the practice of many ship-owners and traders to drop in at the tavern and talk over their prospective profits; and gradually a custom developed of inscribing their names on a blackboard, certifying that the men signing would be jointly liable for the loss of a vessel during a certain voyage. From this crude beginning have grown the world-famous associations in the British Isles. In the United States there are a few Lloyds, two of the principal ones being located in New York—the United States Lloyds and the New York Marine Underwriters.

The scope and definition of a marine policy is, of course, entirely different from a land fire policy. The risks insured against are many, and may be summarized as including all perils of the sea. There are two classes—a voyage and a time policy; the former is generally used in insuring vessels, and the latter for cargoes. There are naturally many clauses governing marine-insurance policies, such as capture, seizure, war, and so on. The life of the insurance on a ship begins at the port from which it is insured until moored for 24 hours at the port to which it is insured. When an insurance is made on freight to be carried under a charter, the policy attaches as soon as the vessel sails, although she may be destined to a distant port for her cargo.

Though single losses to marine underwriters have been small, compared with some of those of fire underwriters, there have been shipwrecks that have lived in marine-insurance men's memories. One of the greatest losses to American marine insurance was that of the American steamer Central America, which foundered off the Cuban coast in September 1857. The Central America was bound from Aspinwall, now Colon, to New York, and was loaded principally with treasure from the California gold-mines. She carried insurance amounting to between \$700,000 and \$800,000, all of which had to be paid by American underwriters. Another notable loss was that of the steamer Erie, which sailed from Pernambuco, Brazil, loaded with coffee, on 1 Jan. 1893, and was burned at sea. Coffee prices were high in those days, and the Erie went down with \$500,000 insurance.

Two losses which not only made inroads on the American marine companies, but which also

seriously crippled the growth of American steam transatlantic service, were the sinking of the steamer Arctic, off Newfoundland, in 1854, by collision, and the disappearance of the steamship Pacific, which sailed from Liverpool for New York in January 1856, and was never heard from. Both steamships belonged to the Collins Line, which was the first one to put on steam-vessels for the Atlantic trade. These early losses were particularly detrimental to American marine insurance, because the companies carried extremely heavy lines in those days. Among the recent heavy losses was that of the steamer Oregon, which was run into and sunk off the Long Island coast in 1886. American marine underwriters had between \$700,000 and \$800,000 on the Oregon's cargo. The loss of the Oregon also showed underwriters how quickly even a properly constructed iron ship sinks. The introduction of iron in place of wood for building vessels has not made any material difference in the rates of insurance, for iron has hazards which wood has not, and *vice versa*.

As to the future of American marine underwriting, it is difficult to prophesy. As trade follows the flag, so marine insurance flourishes in the country with a prosperous merchant marine. The United States is again forging to the front as a great ship-building nation, and this gives American marine underwriters hope that American marine insurance may follow in the wake of the growth of American ship-building.

Insurance Patrol, an organization peculiar to New York and other large cities, which cooperates with the fire department, but is controlled by the combined insurance companies, who support it through the board of fire underwriters. The New York corps was organized in 1835, when there was an epidemic of incendiary fires. The patrol is provided with wagons and an equipment designed for its special work. Its most important service is in saving goods, which it does by removing them from burning buildings, or by covering them with rubber or oiled sheets, as a protection from water, dirt or cinders. In some cities it is known as salvage corps, or protective association.

Insurrection, the act of rising against governmental authority, active opposition to the power of the state. In the United States, power to suppress insurrections by employing the militia is given to Congress by the Constitution, Art. I., Sec. 8, Clause 15. In 1792 and 1807 acts were passed giving the President power to call forth the militia when notified by an associate justice of the Supreme Court or a district judge that the execution of the laws is obstructed, and on application of a legislature or a governor, when the legislature could not be convened, and to employ also the land and naval forces of the United States. The Whiskey Insurrection (q.v.) was directed against the Federal authority and the President employed force to suppress it on notification by the Federal judge. During the Buckshot War (q.v.), in 1838, between the Whigs and Democrats in Pennsylvania, the governor of that State asked for assistance, but it was refused. The governor of Rhode Island made a similar application during the Dorr Rebellion (q.v.) and the regulars were held ready for action, but their aid proved unnecessary. These last two cases came under Art IV., Sec. 4.

INTELLECT — INTERCONTINENTAL RAILWAY

of the Federal Constitution, which provides "that the United States shall protect" each State on application of the legislature, or of the executive (when the legislature cannot be convened), against domestic violence.

When the Civil War began the President was obliged to take prompt steps in calling out the militia, though no application had been made to him as required by the acts of 1792 and 1795. His action was justified by Art. II., Sec. 3, of the Constitution, providing that "he shall take care that the laws be faithfully executed," but Congress on 6 Aug. 1861 formally validated and made legal all of President Lincoln's previous acts, proclamations, and orders. The Force Bill (q.v.), of 20 April 1871 gave the President special power to use military force in certain contingencies. In the South during the reconstruction period, and subsequently in different places at the North, during riots in connection with strikes, the employment of Federal troops has entered as a significant feature into the history of our government.

In'tellect. See MIND; PSYCHOLOGY.

Intent, a legal term signifying the end or object which a person had in the performance of an act, the making of an engagement, or the drawing up of a will. Generally the legal consequences of an act are considered quite independently of the intention of motive of such an act. A wrong done to the person or property of another is punishable at law without consideration of the intentions of the person committing the violence or trespass. But when an engagement has been made by person, or a written disposition of property executed, the intention of the person making the engagement or signing the deed is fair matter for legal inquiry. In this connection a subsequent stipulation by word of mouth is not competent to nullify or modify the terms of a written engagement. Intent also forms an important part in suits for defamation, fraud and negligence. Negligence must have intent to make it criminal, so must defamation and fraud and malicious mischief. Consult Thayer, 'Preliminary Treatise on Evidence' (1898); Black, 'Construction and Interpretation of Laws' (1896); Hardcastle, 'Rules which govern the Construction and Effect of Statutory Law' (1900).

Intent, in psychology, according to James, is that which intelligent consciousness "means or intends"; the intent is a feeling in consciousness which is usually identified or practically identical with the object of consciousness at a particular time. By others, however, the word intent is meant to apply to a certain point of view from which an object may be regarded. Thus when our conscious processes have a unity of interest, there is, as a rule, a certain amount of unity of object. If the interest is divided, more particularly to the attainment of a definite or a vivid knowledge, the object as it becomes more perfectly known is identical with the object as previously less perfectly known; and as one's conscious thought is directed constantly toward the object, it receives, little by little, further and further definite specification, the detail being more or less in the background; yet the detail is all the time in consciousness, as it were inevitably associated with the object itself. The detailed object, considered by Baldwin as the goal of conscious en-

deavor, may be appropriately called the intent of consciousness, for he says "it is what the mind consciously means or intends but has not attained." The end pursued becomes defined in the pursuit of it, and so far as it is yet indefinite, and therefore only partially developed in consciousness, it is an intent. Consult Baldwin, 'Dictionary of Philosophy and Psychology,' Vol. I.

In'tercolumnia'tion, in Greek architecture, the space between two columns. This space is measured in diameters of the foot of the column. Vitruvius mentions five varieties of intercolumniation. These are the *pycnostyle* (that is, with columns thickly ranged) of one diameter and a half, which are least frequently found; the *systyle* (that is, with columns harmoniously ranged) of two diameters, the *diasystyle* (that is, with columns far apart) of three diameters, the *areostyle* (that is, with columns sparsely ranged) of four diameters; and the *eustyle* (that is, with columns a due distance apart) of two and a quarter diameters.

Intercontinent' al Railway, or Pan-American Railway, a proposed line of standard gauge, to connect the railway systems of the United States and Mexico with those of the Argentine Republic, utilizing as far as practicable existing systems in Central and South America. At the first International Conference of American States, held in Washington (1889-90) the committee on railway communications said in their report, "That a railroad connecting all or a majority of the nations represented in this conference will contribute greatly to the development of cordial relations between said nations and the growth of their material interests." President Harrison on 19 May 1890 recommended that Congress should make an appropriation for the share of the United States in the expenses of a preliminary survey. Congress complied, and the Intercontinental Railway Commission began its work with A. J. Cassat as chairman and H. G. Davis at the head of the finance committee. The commission spent about \$360,000 for surveys, maps, etc., three corps of engineers making experimental surveys between the north of Guatemala and Argentina in 1892, 1893, and 1894. It was found that the approximate length of the line to connect the south-eastern boundary of Mexico with Buenos Ayres would be: in Guatemala, 230 miles; Salvador, 220; Honduras, 70; Nicaragua, 224; Costa Rica, 363; Colombia, 1,372; Ecuador, 635; Peru, 1,671; Bolivia, 774, and Argentina, 1,143; total, 6,702. The distance from New York to the Guatemalan frontier is 3,769 miles, and thus the total from New York to Buenos Ayres is 10,471 miles. Links between the termini of the Argentine and Mexican systems: In Bolivia, 192 miles; in Peru, 151 miles; in Nicaragua, 31 miles; in Salvador, 20 miles; in Guatemala, 30 miles. This statement shows that about half of the distance between New York and Buenos Ayres was covered by railways then existing. On 27 Nov. 1901 the Pan-American Railway committee of the Second International Conference held in Mexico City stated that "some additional railroad has been built that could be utilized as a part of a continental system"; that not more than 5,000 miles of road would have to be constructed to establish railway communication between the systems of North and South Amer-

INTERDICT—INTEREST

ica; that \$200,000,000 would be ample for this work; and that the surveys made by the engineers of the commission demonstrated the practicability of constructing all of the missing links. The concluding assertion, however, should be received with caution. In Central America the proposed line runs along the volcanic coast; on entering South America it is continued among the enormous volcanic Andes, still paralleling the Pacific shore, but further inland. Recommendations made by the committee on 27 Nov. 1901 were that a permanent committee on Pan-American Railway should be appointed "to further the project after the adjournment of the conference"; also that the United States should take the lead in sending "competent and reliable persons whose duty it shall be to determine accurately the resources of the different countries and the condition of railway lines in operation . . . and the prospects for business for an intercontinental line . . . and also to ascertain what concessions or assistance each of the respective governments is willing to grant to the enterprise." The permanent committee appointed by the president of the conference comprised Ex-Senator Henry G. Davis and four others. A special commissioner was sent to the Latin-American republics, as suggested.

In'terdict, an ecclesiastical decree which forbids the performance of certain acts of public worship. When an interdict was laid upon a town, district, or country, all the churches were closed, the bells were silent, the sacraments, except infant baptism and extreme unction (and sometimes even these), were withheld, the rites of burial were not performed, and all the public ceremonies of religion were suspended. Interdicts may be general, as applied to a country or city; particular, as applied to a parish or diocese; personal, as applied to a person, or some class of persons. The bishops seem to have anciently exercised the right of publishing interdicts; for in 870 Hincmar, bishop of Laon in France, issued one against a parish in his diocese. One of the earliest censures of this sort on record was imposed upon the city of Rouen in the 6th century on account of the murder of the Archbishop Pretextatus by order of Queen Fredegonda. In 997 Gregory V. laid the kingdom of France under an interdict because King Robert had married his cousin, and the king was abandoned by most of his court. The same penalty was inflicted upon the kingdom of England under Stephen (1147) by Eugenius III., under John (1207) by Innocent III., under Henry VIII. (1535) with little effect by Paul III., and under Elizabeth (1587) by Sixtus V. Adrian IV. laid Rome under an interdict for the purpose of compelling the Romans to drive out Arnold of Brescia. Gregory IX. made use of the same instrument of compulsion in his quarrel with the emperor Frederic II. During the middle ages the interdict was a powerful engine of attack for the popes in their contests with sovereigns, as the popular dread of its effects was so great that kings were often forced by rebellions to submit to almost any conditions in order that it might be taken off. From the time of the reformation general and local interdicts have become rare. When Paul V. laid Venice under an interdict in 1606, the churches were not

closed, and only a minority of the bishops submitted to it.

Interest ("it concerns"—the party in issue—originally an award of damages, later used to evade the anti-interest laws), a charge for the use of money, by custom computed annually, on a basis of so many out of each 100 units loaned; but without diminishing the capital. It is possible to pay interest without loss, because, under conditions now general, the borrowed money can be employed in productive industry, from which a return equal to or greater than the interest can be obtained; or because comfort, prestige, or moral advantages of many kinds are derivable, justifying the expenditure when enough is left. Such borrowing is now useful on the whole, because civilization has ingrained a self-restraint in the masses which makes them in most cases manage money soberly and prudently. But in the early ages this was not so, except in a few developed commercial cities: Babylon carried on business by interest loans, and even bottomry bonds on shipping. Tyre probably did so, the great Athenian commerce was built up entirely by it, as Demosthenes explicitly says, but the mass of people were not fit to have the use of money, had no remunerative employment for it, and borrowed it only to use in self-indulgence, or in desperation because any rate was a choice of evils. There was little property to pledge, and the security was mostly the debtor's person; foreclosure meant selling him for a slave, and the grievance which called for Solon's legislation was the debt-slavery of a large section of the citizens. Hence arose a violent prejudice against the system altogether, as immoral in itself; the law of Moses prohibited it between Jew and Jew; Aristotle says it is essentially immoral, because money cannot breed money (this in the age of Athenian commerce), and never was meant for any such use; the Christian Church inherited the reprobation from the Jewish, and for many centuries forbade its members to take "usury" (money for the use of money, that is, interest at any percentage), and the secular laws were correspondent. In England interest did not become legal till the time of Henry VIII., but had been actually practised for many generations, by legal fictions of partnership or breach of contract, etc.; previously it was in the hands of the Jews—who were so indispensable as financial agents that a Jew who was converted to Christianity had all his property confiscated—and later of the Lombards. The first English permissive statutes fixed 10 per cent as the legal limit that might be charged; early in the 17th century it was set at 5. No serious doubt of the power of governments to regulate the current rate of interest obtainable was entertained till Bentham wrote his 'Defence of Usury' in 1786, proving that the laws could not possibly have any effect; because if the legal rate fixed was equal to or greater than the current rate it could not work any change in it; and if less, holders of money would not lend without obtaining their price plus an insurance for the risk of legal punishment. The doctrine was violently disliked, and has not even yet overcome the determination of the mass to show their dislike of usury by statute, or their belief that they can affect rates; but in a few American States of late years the anti-usury laws have been abol-

INTEREST—INTERFERENCE

ished. Of course a legal rate is always provided in default of contract.

Interest is not a natural right, but a matter of law or contract. The holder of a note payable without stipulation of interest cannot claim any until the note has become due and remains unpaid; thenceforward it draws money at the legal rate. The United States pays no interest on its debts, except where bonds are issued specifying it.

Of the separate States and Territories there is no legal restriction on the rate allowable by contract in Arizona, California, Colorado, Connecticut, Maine, Massachusetts, Nevada, Rhode Island, Tennessee, Utah, or Washington; the legal rate in each is 6 per cent except with Colorado (8), Nevada (7), Utah and Washington (8). The others have rates as follows, the legal rate coming first, then the contract rate permitted: Alabama, 8, 8; Arkansas, 6, 10; Delaware, 6, 6; Florida, 8, 10; Georgia, 7, 8; Idaho, 7, 12; Illinois, 5, 7; Indiana, 6, 8; Iowa, 6, 8; Kansas, 6, 10; Kentucky, 6, 6; Louisiana, 5, 8; Maryland, 6, 6; Michigan, 5, 7; Minnesota, 6, 10; Mississippi, 6, 10; Missouri, 6, 8; Montana, 7, 12; Nebraska, 8, 8; New Hampshire, 6, 6; New Jersey, 6, 8; New Mexico, 6, 12; New York, 6, 6; North Carolina, 6, 6; North Dakota, 6, 12; Ohio, 6, 8; Oklahoma, 7, 12; Oregon, 8, 10; Pennsylvania, 6, 6; South Carolina, 7, 8; South Dakota, 7, 12; Texas, 8, 10; Vermont, 6, 6; Virginia, 6, 6; West Virginia, 6, 6; Wisconsin, 7, 10; Wyoming, 8, 12. The rates in the District of Columbia are 6, 10.

That these provisions are more the result of tenacious tradition than of any very exact reasoning is shown by their terms. Only in three States—Illinois, Louisiana, and Michigan—has there been any recent attempt to keep down by law the rate of contractual interest to the rate actually current in the community; in the others, unspecified debts bear 6 to 8 per cent interest while the current rate is 5. As to the contract interest, 11 States stick to the attempt to forbid anything beyond the legal rate; but that assumed interest being above current rates, some leeway is left. One of these, moreover—New York—favors its peculiar interest by allowing any contract rate on "call loans" over \$5,000. Sixteen make the rate so high—from 10 to 12 per cent—that any one with the least pretense of credit or security can contract freely; above that, we have to deal with pawnbrokers and "fences," the former protected by tacit allowance, the latter amenable only to criminal legislation.

The theories of interest, like most economic principles, are much disputed by economists. The chief theories are those of "abstinence," holding interest to be a reward of abstinence from using up the capital in enjoyment (a variant of this regards it as a result of the general appreciation of the present above the future); of "productivity," holding it to be the return for production by capital in the same way that wages are a return for production by labor; the combination of the two, regarding the return as fixed by supply and demand, the latter depending on productivity and the former on abstinence; and the "monopoly" theory, which considers it a toll levied on the product of labor by the capitalists who control the means of production.

Interest, in psychology, is a term by which at least two or three different things may be meant. On the one hand interest may be defined as the consciousness which accompanies mental tendencies of any sort so far as they are concentrated on mental objects. It is manifested by a certain amount of voluntary attention to which it may be considered a stimulus. The exploiting habit, curiosity, the desire to know, may be defined as primary forms of interest, as distinguished from custom and habit and one's way of regarding things, the former being regarded by Baldwin in the nature of a stimulus to the intellectual function, the latter as frequent performance of a process.

The word also, in the vulgar sense, applies loosely to what is meant by personal advantage; as, for instance, it is "to a man's interest" to obtain such and such.

In pedagogics interest is often looked upon as a form of amusement, a stimulus through the play-instinct to induce intellectual effort. In the science of teaching, the ideal is to awaken an interest in the ends for which pupils study, and that a permanent interest in the ends should be fostered through the means. Baldwin well says that when interest attaches to the end, but not to the means of reaching it, we have drudgery, as in the case of workmen who think only of the dollar, taking no interest in the labor that wins it; on the other hand, when there is interest in the means, but not in the end, we have play, we do not work. When, however, there is interest in the end to be obtained, and also in the means for reaching the end, the ideal of work desirable in education is reached. See Herbart, 'Science of Education'; 'Doctrines of Interest'; Baldwin, 'Story of the Mind'; 'Educational Review,' Vol. X.; Baldwin, 'Dictionary of Philosophy and Psychology,' Vol. I.

Interference, in physics, is a phenomenon exhibited by wave motion of all kinds, and consists in the coming together of waves having different phases, in such a way that the effects of the waves are either increased or diminished. Interference may be observed when two different trains of waves come together upon the surface of water or any other liquid. Where the crest of a wave belonging to one system coincides with the crest of a wave of the other system, the elevation of the water surface is sensibly equal to the sum of the heights that the separate waves would have if each existed in the same place alone. When a crest of one of the waves coincides with the trough of another, the disturbance of the water surface is reduced, and the elevation (or depression) which results is equal to the difference between the elevation of one of the component waves and the depression of the other one.

The kinds of interference that are of the greatest practical importance in physics are those which occur among sound waves, or among waves of light. The phenomena in these cases are ultimately of the same general sort as those observed upon the surface of water. In the case of sound, interference may even produce entire silence in certain regions, when two trains of sound waves, of equal intensity, are brought together in a suitable manner. A more familiar result of the interference of sound waves, however, is the production of "beats," when two or

INTERIOR — INTERNAL IMPROVEMENTS

more trains of waves, having but slightly different wave-length, come together while the two are moving in nearly the same direction. This phenomenon is exhaustively treated in Helmholz's 'Sensations of Tone,' and it also receives a more or less adequate treatment in all of the better works on physics.

The more familiar of the interference phenomena that are afforded by light are those which are observed in connection with soap bubbles and with very thin plates of transparent solids. Light, upon striking the soap bubble or the thin plate, is reflected toward the eye from both surfaces, and the trains of light waves that reach the eye from these two sources, since they have a slight difference of phase (which varies, moreover, from point to point of the bubble or the plate), interfere with one another so as to produce effects that are often very beautiful and striking. A soap bubble, when viewed by monochromatic light, often appears to be covered with dark striae; the dark lines being due to the fact that at the points that appear dark the two trains of light-waves, coming respectively from the inner and outer surfaces of the soap bubble, nearly or completely neutralize each other. When the bubble is viewed by white light, we do not commonly see the dark striae, their places being taken by bands of color. This is because the different colors that compose white light have different wave-lengths, so that at any given point in the bubble only a portion of the colors are destroyed by interference, leaving the remaining constituents of the white light to produce their full chromatic effect upon the eye. See LIGHT; SOUND; PHYSICAL CRYSTALLOGRAPHY.

Interior, Department of the, one of the executive departments of the United States government whose heads are cabinet secretaries. The "home department," long existent in all European governments, was only constituted in this country by act of 3 March 1849. Its functions had previously been exercised by bureaus or officials of nearly all the other departments: patents, copyrights, public documents, and the census belonged to the State Department; public lands, mines, and judicial accounts, to the Treasury; Indian affairs, to the War Department; and pensions to the War and Navy, each for its own pensioners. By later laws the Interior was given charge of education, public surveys (including the geological survey; but the coast and geodetic survey belongs to the Treasury), subsidized railroads, Territories, national parks and reservations, returns of public contracts made by several other departments, some charitable institutions in the District of Columbia, and a number of other matters. The secretary makes an annual report of the number of public documents received and distributed. He has a salary of \$10,000, and two assistant secretaries. His office has seven divisions: appointments, disbursements, lands and railroads, Indian affairs, pensions and miscellaneous, public documents, and stationery and printing. Although most of these are managed by commissions appointed by the President, their work is under the secretary's direction, and their reports are made through him. Most of the clerks and subordinate officers in the bureaus are appointed by him. All patents issued by the

United States must be signed by him. The first secretary was Thomas Ewing of Ohio.

Interlaken, in'tér'läk'ēn ("between the lakes"), Switzerland, village in the canton, and 26 miles southeast of the town of Berne, one mile southeast of Unterseen, beautifully situated near the left bank of the Aar, in the valley of Boedeli, between the lakes of Thun and Brienz. It contains a beautiful old castle and numerous hotels. It is visited annually by 80,000 to 100,000 tourists. Pop. about 2,500.

Internal Improvements, the construction and reparation of roads, bridges, canals, harbors, lighthouses, etc., at the expense of the United States government. The Constitution not having made any provision for such improvements, the execution of public works of this character became subject to the vicissitudes of party politics. Yet since 1789 funds have been perpetually appropriated by Congress for the carrying on of improvements throughout the country, so long as these lay strictly within Federal jurisdiction. Such would include lighthouses, buoys, beacons and public piers, rivers and harbors. The Federalist party, and after it the Democratic party, opposed all improvements on rivers and roads, the benefit of which passes to the several States. Yet in 1806 an appropriation was made for the construction of the Cumberland Road, which should penetrate the Western States and facilitate the mail service, as well as open up unsettled territory to the increasing tide of immigration, and serve for the transportation of troops and army supplies. The Federal Government, about the same time, undertook the construction of a road through Georgia toward New Orleans. In 1808 Congress passed a resolution in which it claimed the power to make appropriations for such internal improvements as the construction of roads and canals, and the maintenance and direction of water courses. Such roads and canals as the President should consider of Federal importance were ordered by Congress to be surveyed, and \$300,000 was subscribed to stock of the Chesapeake and Delaware Canal. But there was a wide difference of opinion with regard to the constitutionality of such legislative action, and in May 1822, President Monroe vetoed the Cumberland Road bill. He supported this procedure by the declaration that Congress had acted *ultra vires*. That body, he maintained, had no right under the Constitution to carry out such internal improvements at Federal expense. President Jackson in 1830 followed Monroe's example and vetoed the Maysville Turnpike Road bill. Henceforth, the matter of such internal improvements was left to the legislation of the various States. Jackson had somewhat mitigated the force of his veto by advocating the distribution of the Treasury surplus among the various States, but when the Whigs tried to put this into execution in 1841, President Tyler by his veto put a stop to any such attempts, and they have never since been repeated. The introduction of railroads under the management of private corporations did away with the call for road appropriations, although something like a bonus was given to the projectors of new lines by the vast grants of lands which were made to them. Tracts of 40,000,000 and 50,000,000 acres were thus transferred to railroad companies. At

INTERNAL REVENUE SYSTEM — INTERNATIONAL BROTHERHOOD

present both the great political parties are inclined to reclaim so much of the public lands thus granted, as has not been earned by a strict fulfilment of the conditions on which the grant was made. The appropriations for internal improvements under the head Rivers and Harbors for the year 1903 was \$32,540,199.50 as against \$7,046,623.00 in 1902.

Internal Revenue System, of the United States, properly all taxation except that of foreign goods at customs offices; but in use restricted to what were formerly termed excises (q.v.), on internal trade and manufactures, through a bureau of the Treasury Department, organized 1862. Before that time, though excises had been imposed, they were unpopular and brief. An intense dislike to them had been inherited from England, where they traditionally connoted an independent revenue for the sovereigns to free them from popular control, and arbitrary interference with private business and persons by irresponsible officials, the raw state of trade and manufacture in this country made a general excise system very injurious; and the customs dues amply provided for the expenses.

The first occasion when they were resorted to was just after the adoption of the Constitution. The assumption of the State debts, and other expenses of the new government, compelled Hamilton to recommend an excise, though in the 'Federalist' and elsewhere he had strongly urged its impolicy; he was also anxious to test the power of the government to enforce taxation, which the Articles of Confederation could not. On 3 March 1791 a bill was passed taxing distilled spirits of domestic manufacture. In the then West (western Pennsylvania) the still was like the New England cider mill, but much more important, because the long distances and bad roads made corn unprofitable unless condensed into whiskey, hence there was open revolt, which had to be put down by national troops (1794). Direct resistance ceased, but the tax was largely evaded, and it was two years before it was extended to Kentucky and Tennessee, while the collections in North Carolina were poor. In 1794 the system was extended in fear of a war with England, but owing to unskilful choice of articles or provisions in detail, the only one which produced much was that on sugar, from the high import duty, which gave the home market to the domestic manufacturers, so that what went into excise came off customs. Stamp taxes were laid in 1797, but were of odious associations. With the election of Jefferson as President the whole system came under ban, the Democrats having always opposed it, and on 6 April 1802 the entire internal taxes were repealed, with nearly \$700,000 outstanding and uncollected, and which remained so. The dislike was not to the taxes as such, but to the inquisitorial methods of collection involved; and this persisted. But the War of 1812 compelled a renewal of them: unfortunately they were laid so late that the war was over before they began to produce much. They were needed to pay off the war debts, however, and were retained till 23 Dec. 1817. Thence till the Civil War no internal tax of any kind was levied in the United States.

The first real "system"—for the others included but few articles—and which has become a standing part of our system of taxation,

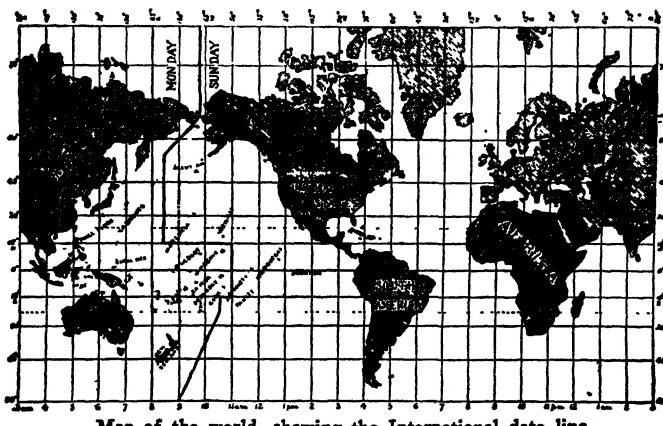

was inaugurated 1 July 1862, others followed, placing an enormous and very ill-distributed burden on the people, which they bore uncomplainingly for the end in view. It is almost too complimentary to call it a system, as it was an indiscriminate heaping of taxes upon every stage of every article, on labor and tools, raw materials and finished products, processes and professions. Articles paid sometimes a dozen taxes on the various stages, and another on the final one, before reaching even the wholesaler to begin a round of middlemen's profits. "The only principle recognized," says David A. Wells, "if it can be called a principle, was akin to that at Donnybrook Fair, 'Wherever you see a head hit it.' " "Wherever you find an article, a product, a trade, a profession, or a source of income, tax it!" Within the period 1861-7 no less than 25 revenue bills were passed by Congress. The incessant endeavor was to find new objects of taxation. The industrial effects of the sudden huge unequal burdens, and the political effects of the enormous revenue to spend at discretion, cannot be discussed here. The taxes did not begin to produce largely at once; in 1863 the receipts were \$37,640,787.95; in 1864, \$109,741,136.10; in 1865, \$209,404,215.25; in 1866, the summit, \$300,226,813.42. Then the items began to be stricken off, the total sinking by 1873 to \$113,729,314.14: able business men have attributed part of the inflation, and consequent panic, to the sudden removal of burdens to which business had adjusted itself. The next year it touched bottom, \$102,409,784.90. The taxes by this time had been reduced to about the present status, and tended to increase with the growth of the country, even rising somewhat through the bad years 1875-9. The income tax, though fairly productive—the height being \$37,775,873 in 1870—was dropped in 1872; no other tax was ever so unpopular, from its prying into private secrets, and its working through informers. It is also the one which bears hardest on the most heavily burdened class of the community, the moderately salaried men in various callings. Protection leaders have repeatedly urged or hinted at repeal of all internal taxes, to prevent any reduction of customs duties; but the moral feeling reinforces the economic sense of the people in insisting on liquors and tobacco being taxed. Attempts have been made to increase the revenue from liquors by raising the tax; but the result is the reverse, the premium on fraud being too great. In 1894 the income tax was re-established, but the Supreme Court decided it unconstitutional under its particular terms. On 1 July 1898, to provide for the expenses of the Spanish War, fresh internal taxes were laid; of which the most fertile were stamps on all mercantile papers, telegrams, etc., and on patent medicines, and wines, which yielded in the ensuing fiscal year \$43,837,816.66. Special taxes on bankers and amusements, and some other things, yielded several millions. The total receipts in 1899 were \$273,484,571.44. In 1901 and 1902 the new taxes were all abolished.

International Brotherhood of Maintenance-of-Way Employees, an American labor union, having a department of fraternal insurance. It was founded at Demopolis, Ala.,

INTERNATIONAL DATE LINE

in 1887, and had a membership in 1903 of 40,000. Since its organization the society has disbursed \$500,000 in death and disability benefits. It has secured increased wages for maintenance-of-way employees to the amount of \$6,000,000 annually. It was actively engaged in the great strike on the Canadian Pacific Railway in 1901. The strike was settled after a struggle lasting 11 weeks, with the understanding that all members of the brotherhood would be reinstated in their former positions within two weeks; the question of wages to be left to arbitration. Sir John A. Boyd, Chief Justice of Ontario, was chosen chairman of the Board of Arbitration and awarded the employees an increase of 20 per cent over previous wages. The brotherhood has secured trade agreements for its members from a number of the largest railway systems of the United States and Canada. It also holds a charter of affiliation with the American Federation of Labor, and publishes the 'Advance Advocate,' a magazine devoted to the interests of maintenance-of-way employees. See RAILWAY LABOR ORGANIZATIONS.

International Date Line, an imaginary line

Map of the world, showing the International date line.

drawn through the Pacific Ocean somewhat irregularly, but tending in a general northerly and southerly direction, and separating the islands of the Pacific Ocean in such a way that all those which lie to the east of it carry the same date as the United States, while all those on the west of it carry the same date as Japan and Australia. The nature of this line may be made clear by the following illustration: A traveler leaves New York city at noon on Sunday, and proceeds westward just as fast as the earth turns on its axis, so that he follows the sun in its apparent westward progress with such precision that he keeps it always directly south of him. It will be noon, therefore, at every place he passes. If, however, he asks the day of the week at every point of his journey, he will be told that it is Sunday at all points in the United States, and even as far west as Hawaii. This can not hold true indefinitely, however, because when he has gone entirely around the world, and has returned to New York, he will have been gone 24 hours, and will therefore be told that it is Monday noon. Everywhere in

Europe, too, he would have been told that it is Monday noon.

Yet it has always been the same day to him, and there must have been some place on the journey where he was told, for the first time, that the day was Monday instead of Sunday. At this place, if he wishes to be in accord with the people that he meets, he must arbitrarily change the name of his day from Sunday to Monday. Mariners are in the habit of making the change upon crossing the 180th meridian from Greenwich, England; but this fact is of no service to us if we wish to compare the date carried on one of the Pacific Islands with the corresponding date (say) at New York, because the mariners pay no attention to the local dates on the islands that they pass. The ideal way to find out where the date actually does change would be to canvass the entire Pacific Ocean, so as to find out what date is actually in use on every one of its islands at some given instant. A line drawn from pole to pole in such a manner as to keep all islands bearing one date on one side and all islands bearing the other date on the other side, would afford a perfectly definite basis for the comparison of dates, and would be the true "International Date Line."

No such canvass has yet been made. As a general rule, it may be said that the date now in use upon most of the different islands or groups, is the date which results from the one carried there by the first European or American colonists; and this date will presumably be different according as the colonists came from the east or the west. This is not true universally, however, because arbitrary changes in the date are known to have been made in a number of cases. For example, Alaska was first colonized by the Russians, who brought with them the Russian date. When the American settlers moved there, they carried with them the date of the United States, and this led to some considerable confusion, the Sunday of the Americans being the Monday of the Russians, in spite of the fact that the Russians still use the Julian calendar. In 1867, when Alaska was purchased from Russia, the date in use there was made to conform to that used in the United States. Again, the Philippines were discovered by Magellan, in 1521, and Manila was founded by Lagaspi in 1571. Magellan brought his date from the east, and after the islands were colonized they kept the same date as the Spanish possessions on the opposite side of the Pacific; and they therefore carried a different date from that prevailing on the neighboring Asiatic coast. This was changed in 1844, by the omission of the 31st day of December in that year from the Philippine calendar; this change bringing the date in use in the Philippines into harmony with that prevailing at Hong Kong and other Asiatic ports. The best data at present available indicates that the date line follows substantially the course shown upon the accompanying map,

INTERNATIONAL LAW

which is prepared from data furnished by the United States Naval Observatory. This date line is subject to modification, as our knowledge of the dates carried on the various Pacific Islands increases.

International Law, the law of nations; those rules or maxims which independent political societies or states observe, or ought to observe, in their conduct toward one another. International law is divisible into two heads: the one which regulates the rights, intercourse, and obligations of nations, as such, with each other; the other, which regulates the rights and obligations more immediately belonging to their respective subjects. Thus the rights and duties of ambassadors belong to that head which respects the nation in its sovereign capacity; and the rights of the subjects of one nation to property situated within the territory of another nation, belong to the latter head. Some of the maxims regarding the rights and duties of nations during a state of peace are:

1. Every nation is bound to abstain from all interference with the domains of other nations.

2. All nations have equal and common rights on the high seas, and they are not bound to admit any superiority there. The sea which washes the coast of a nation, to the extent of three miles, is now deemed to be a part of the territory of the nation, over which it may exercise an exclusive jurisdiction. And, in respect to persons subjected to its laws, every nation now claims a right to exercise jurisdiction on the high seas, for the purpose of enforcing both international law and its own municipal regulations.

3. No nation has a right to pursue any criminal or fugitive from justice in a foreign country; its claim, if any, is a mere right to demand him from the nation in which he has taken refuge.

4. Every nation has a right to regulate its own intercourse and commerce with other nations.

5. Foreigners are bound to obey the laws of a country as long as they reside within it, and under its protection; and the property held by foreigners within a country ought to be protected in the same manner as that of natives.

6. Every nation has a right to send and to receive ambassadors and other public ministers; and this right of embassy has always been deemed peculiarly sacred. Their persons are held sacred and inviolable. Their property, and servants, and retinue enjoy a like privilege.

7. It is through the medium of ambassadors and other public ministers that treaties, conventions, and other compacts between nations are usually negotiated, thus forming a positive code for the regulation of their mutual rights, duties, and interests. In the modern practice of nations such treaties and compacts are not generally deemed final and conclusive until they have been ratified by the respective governments to which the negotiators belong.

War introduces an entirely new order of rules. The right of declaring war results from the right of a nation to preserve its own existence, its own liberties, and its own essential interests. In a state of nature men have a right to employ force in self-defense; and when they enter into society this right is transferred to the

government, and is an incident to sovereignty. What are just causes for entering into a war is a question which has been much discussed by publicists. Defensive wars are necessarily justifiable from the fact that they involve the existence or safety of the nation and its interests. But offensive wars are of a very different character, and can be justified only in cases of aggravated wrongs or vital injuries. The first effect of a declaration of war is to put all the subjects of each of the nations in a state of hostility to each other. All the property belonging to each is deemed hostile. If it be personal property it may be captured as prize; if lands, it may be seized and confiscated at the pleasure of the sovereign; if it be merely in debts or stock it may, in the extreme exercise of the laws of war, be equally liable to confiscation. As soon as a battle is over the conquerors are bound to treat the wounded with kindness, and the prisoners with a decent humanity. And there are some things which seem positively prohibited from their cruelty and brutal barbarity; such are the violation of female captives, the torturing of prisoners, the poisoning of wells, the use of inhuman instruments of war. In time of war there is occasionally an intercourse between the belligerents which should always be held sacred. Thus the interchange of prisoners by cartels; the temporary suspension of hostilities by truces; the passage of flags of truce; the engaging in treaties of capitulation. When any conquest of territory is made the inhabitants pass under the dominion of the conqueror, and are subject to such laws as he chooses to impose upon them. There are also certain rights which war confers on the belligerents in respect to neutrals. Thus they have a right to blockade the ports or besiege the cities of their enemies, and to interdict all trade by neutrals with them. But no blockade is to be recognized unless "the besieging force can apply its power to every point in the blockaded state." They have a right also to insist that neutrals shall conduct themselves with good faith, and abstain from all interference in the contest by supplying their enemy with things contraband of war. And hence arises the incidental right of search of ships on the high seas for the detection of contraband goods. A neutral nation is bound to observe entire impartiality between the belligerents. Neutral nations are, strictly speaking, bound to compel their subjects to abstain from every interference in the war, as by carrying contraband goods, serving in the hostile army, furnishing supplies, etc. Subject to the exceptions above referred to, a neutral has a right to insist upon carrying on its ordinary commerce with each of the belligerents in the same manner as in times of peace. See DIPLOMACY; HAGUE CONFERENCE; NEUTRALITY.

International Law, Recent History and Development of. Nothing could better exemplify the fallacy of drawing from present ills despondent prophecies of evil than a comparison of the state of international law at the close of the 19th century with its condition at the beginning. The wars in the midst of which the century opened were not only world-wide in their effects, but they were characterized by a defiant disregard and systematic violation of the rules of international conduct. As early as 1793 both France and Great Britain, soon after the war broke out be-

INTERNATIONAL LAW

tween them, sought to interrupt the lawful course of neutral trade. With this object each power adopted measures the injurious effects of which were greatly aggravated by the irregular and arbitrary manner in which they were executed.

The Peace of Amiens proved to be but a brief truce, and after the war was renewed even greater excesses were perpetrated. The idea of conquering England by destroying her trade, though it did not originate with Napoleon, was the inspiration of his so-called Continental system. On 28 March 1806, Prussia, after taking possession of Hanover, published, in pursuance of her agreement with Napoleon, a proclamation which purported to close the ports of the North Sea, as well as all rivers running into it, against British ships and trade. The British government sought to retaliate by an Order in Council which declared the mouths of the Ems, the Weser, the Elbe, and the Trave to be in a state of blockade. Napoleon then issued his famous Berlin decree, by which he assumed to blockade the British Isles, and to prohibit all commerce and correspondence with them. Great Britain's response was an Order in Council not only forbidding neutral vessels to trade between ports in the control of France or her allies, but also forbidding them to trade, without a clearance obtained in a British port, with the ports of France and her allies, or with any port in Europe from which the British flag was excluded. Napoleon's answer was the Milan decree, declaring every vessel that had submitted to search by an English ship, or consented to a voyage to England, or paid any tax to the English government, and every vessel that should sail to or from a port in Great Britain or her possessions, or in any country occupied by British troops, to be denationalized and to be good prize. By these measures the right of neutrals to hold commercial intercourse with belligerents was virtually denied, each belligerent endeavoring under the guise of blockades, which existed only on paper, to prevent all trade that could not be made subservient to its interests. It is hardly conceivable that any power would now venture to assert such pretensions. They were at the time scarcely defended on legal grounds; and in the declaration of Paris of 1856, to which both France and Great Britain are parties, it is expressly recorded that "blockades, in order to be binding, must be effective." This rule is recognized as but the expression of a principle of international law. The illegality of paper blockades is to-day universally acknowledged.

No less important than the subject of neutral rights is that of neutral duties. The first authoritative formulation of the duties resulting from a state of neutrality is to be sought in the executive, legislative, and judicial acts of the United States in 1793 and 1794, during the first series of European wars growing out of the French Revolution. But on the foundations then laid there has been built up an elaborate and well-regulated system, the obligatory character of which is not now questioned. The comprehensive neutrality statute of the United States of 20 April 1818, became in the following year the model of an act of the British Parliament. From time to time laws and regulations were adopted by other governments, and the duties of neutrality became a determinate part of international law. The final vindication of the system as the ultimate standard of international

obligation and responsibility was made in the case of the Alabama claims.

In the discussion and practice of neutrality, rules have naturally been formulated as to what constitutes a state of belligerency, and as to the conditions under which it should be recognized. The recognition of belligerency presupposes the existence of a state of war in the international sense, and necessarily implies that the parties to the conflict may exercise toward each other and toward third powers such rights as war gives. But on or near the border line that divides peace from war there stands pacific blockade, a measure of recent invention, the precise legal position of which has not been authoritatively determined.

During the first half of the 19th century a fruitful subject of controversy was that of visitation and search. That belligerent cruisers might lawfully visit and search the merchant vessels of neutrals on the high seas, for the purpose of enforcing the observance of the laws of war, was on all hands admitted; but in certain cases, as in that of the impressment of seamen, the belligerent right of search was sought to be employed for other purposes; and it was even asserted that a right of search existed in time of peace, especially for the purpose of putting an end to the slave trade. These pretensions were vigorously resisted, especially by the United States. In 1858 the Senate unanimously resolved:

That American vessels on the high seas in time of peace, bearing the American flag, remain under the jurisdiction of the country to which they belong, and therefore any visitation, molestation, or detention of such vessels by force, or by the exhibition of force, on the part of a foreign power, is in derogation of the sovereignty of the United States.

"After the passage of this resolution," said Mr. Fish, as secretary of state, "Great Britain formally recognized the principle thus announced, and other maritime powers and writers on international law all assert it."

It would be difficult to overestimate the importance, both theoretically and practically, of the establishment in the 19th century of the freedom of vessels on the high seas from visitation and search in time of peace. It was the acknowledgment of this principle that made the seas really free and gave freedom to commerce. Nor does the freedom of the seas become less important with lapse of time. As a principle it grows rather than diminishes in the estimation of mankind; for, in the light of history, its evolution is seen to mark the progress of commerce from a semi-barbarous condition, in which it was exposed to constant violence, to its present state of prosperous security.

Closely related to the principle of the freedom of the seas is the question of the navigation of the narrow channels by which they may be connected. This question has been discussed in respect to natural channels in several cases, the most notable of which was that of the dues charged on vessels and their cargoes passing through the Danish Sound and Belts. By treaties made with the interested powers, in 1857, Denmark relinquished the dues, the powers paying her a lump sum, in consideration not only of her renunciation of her claims to tolls, but also of her agreement to maintain such lights, buoys, and pilot establishments as the trade of the Baltic might require. An artificial channel necessarily involves special considerations. Its

INTERNATIONAL LAW

construction requires the expenditure of money and gives rise to proprietary rights; and it is not denied that those rights may be asserted by the exaction of tolls. In this respect the navigation of the artificial channel obviously cannot be free. But, though it cannot be said that the subject has been authoritatively settled as a part of international law, a tendency has been shown in the case of great international highways to act on analogies and to make the artificial channel free in the sense that it shall be open to the ships and merchandise of all nations on equal terms.

While the right freely to navigate the seas has been established, a great advance has been made toward assuring the free navigation of waters flowing into the sea in cases in which they wash in their navigable course the territory of two or more states. By the treaty of Vienna of 9 June 1815, it was agreed that rivers which separated or traversed two or more states should, along their whole navigable course, be, in respect of commerce, entirely free to everyone, subject to regulations of police. This principle was applied primarily to the Rhine, but was also expressly extended to the Neckar, the Main, the Moselle, the Meuse, and the Scheldt. With a limitation of the right of free navigation in some instances to the citizens or subjects of the riparian powers, similar stipulations may be found in treaties relating to the rivers and canals of the ancient kingdom of Poland; to the Elbe, Po, Pruth, Douro, Danube, and other rivers in Europe; and to the rivers La Plata, Paraguay, Uruguay, St. Lawrence, Yukon, Porcupine, and Stikine in America. By an imperial decree of 7 Dec. 1866, the government of Brazil opened "to vessels of all nations," after a certain day, the Amazon as far as the frontiers of Brazil; the Tocantins, as far as Cameta; the Tapajos, as far as Santarem; the Madeira, as far as Borda; the Negro, as far as Manáos; and the San Francisco, as far as the city of Penedo.

The principle of freedom, which has been so widely extended in commerce and in navigation, has also been acknowledged in matters of government. Such an acknowledgment may be seen in the established rule that new states and new governments are entitled to recognition on the ground of their *de facto* existence. The old theory of legitimacy and divine right found its last practical assertion in the acts of the powers composing the Holy Alliance, who, in their various circulars, associated "revolt and crime," denounced "as equally null and disallowed by the public law of Europe, any pretended reform effected by revolt and open force," and announced their determination "to repel the maxim or rebellion, in whatever place and under whatever form it might show itself." Their acts corresponded with their words; but they were soon forced by the progress of events to abandon their ground, and to admit in practice the principle which they had condemned.

In the last 100 years there has been witnessed a change in the law relating to the acquisition of territory by occupation. In former times, when so large a part of the world was unsettled, great weight was given to the mere fact of discovery. Under the papal bull of 1493, and the Treaty of Tordesillas of the following year, Spain and Portugal sought to divide between themselves on that ground the whole

unknown world. Even the early English charters asserted the British title to extend from the Atlantic to the Pacific. In the 19th century, and particularly in the latter half of it, the powers, especially in respect to territorial claims in Africa, recognized more clearly than was ever done before the necessity of actual and effective occupation as the basis of permanent national title.

In the system of extradition, which is chiefly the development of the 19th century, we find one of the many evidences of the growth among nations of a clearer perception of the duty of promoting common social ends. In former times there existed a strong repugnance to the surrender of fugitives from justice. This was due partly to the ancient idea of asylum, partly to perverse notions of national dignity, but perhaps in largest measure to ignorant and groundless prejudices. It was not, indeed, until the middle of the 19th century that the great expansion of the system may be said to have begun. Since that time, however, its growth has been rapid and far-reaching.

An increasing tendency to acknowledge the force and supremacy of law may be seen in the growing frequency of arbitrations for the settlement of disputes between nations, not only as to the rights of individuals, but also as to their own rights, as well as in the recent efforts to establish a permanent system of arbitration, as proposed in the plan of the International American Conference (1890), in the unratified treaty between Great Britain and the United States (1897), and in the convention adopted at The Hague (1899). During the 19th century there were, exclusive of cases still pending, at least 136 international arbitrations. Probably there were more, though certain lists lately circulated, by which the number appears to have been vastly greater, are quite inaccurate, since they include not only numerous cases of mediation, but also ordinary boundary surveys, domestic commissions, and even pure diplomatic negotiations. Both in number of arbitrations and in importance of the questions involved in them, the United States and Great Britain easily lead the way.

There are two modes in which international law may be developed. The first is the general and gradual transformation of international opinion and practice; the second is the specific adoption of a rule of action by an act in its nature legislative. The operation of the former mode it is often difficult to follow in its details, but its effects are potent and undeniable. Perhaps its clearest and most definite exposition may be found in the opinion of the Supreme Court of the United States in the case of the Spanish fishing-smacks, the Paquete Habana and the Lola (the Paquete Habana, 175 U. S. 677). The particular point decided was that coast fishing-vessels, with their implements and supplies, cargoes and crews, unarmed and honestly pursuing the peaceful calling of catching and bringing in fresh fish, are exempt from capture as prize of war. In reaching this conclusion, the Court considered the question whether the exemption was merely a matter of "comity," or whether it was a matter of legal right to which the Court was bound to give effect. In behalf of those who sought the condemnation of the vessels there was cited an opinion of Lord Stowell, in which it was said to be "a rule of comity only, and not of legal decision." With reference to this statement, Justice Gray,

INTERNATIONAL LAW

who delivered the opinion of the Supreme Court, said:

The word "comity" was apparently used by Lord Stowell as synonymous with courtesy or good-will. But the period of a hundred years which has since elapsed is amply sufficient to have enabled what originally may have rested in custom or comity, courtesy or concession, to grow, by the general assent of civilized nations, into a settled rule of international law. As well said by Sir James Mackintosh: "In the present century a slow and silent, but very substantial mitigation has taken place in the practice of war; and in proportion as that mitigated practice has received the sanction of time, it is raised from the rank of mere usage and becomes part of the law of nations."

The importance of this judicial declaration, in its bearing on the development of international law, it is difficult to overestimate. Even the most eminent judges have seemed at times to labor under the impression that it was somehow the peculiar prerogative of a remote age to fix by its customs, however rude and barbarous they may have been, an immutable law in comparison with which the practices of modern times are merely "comity" or "courtesy," which may be discarded at will. The enlightened declaration of the Supreme Court, which was the very foundation of its decision, should have a potent effect in clearing away the misconceptions on which many well-known dicta, of an opposite effect, are founded.

The last century was, however, specially distinguished for the modification and improvement of international law by what may be called acts of international legislation. Among the sources of international law the publicists commonly enumerate the stipulations of treaties. Where a certain rule of action is uniformly embodied in a succession of treaties between the leading powers of the world, it assumes in course of time the character of a principle of international law. But in the latter part of the 19th century, immediate and important results were directly produced by means of international conferences.

Allusion has already been made to the effort of the Congress of Vienna to establish the free navigation of international rivers as a general principle. By the same congress an important contribution to international law was made in the form of rules to regulate the rank and precedence of diplomatic agents. By those alone who are familiar with the annals of diplomacy can the delicacy and interest of this subject be fully appreciated. It had probably given rise to more disputes and caused a greater waste of time than any other within the whole range of international relations. The rules of the Congress of Vienna, slightly modified by the Congress of Aix-la-Chapelle in 1818, were accepted by all the powers which then composed the international circle. They divide diplomatic agents into four classes: (1) Ambassadors, legates, and nuncios, who, in a sense, specially represent the person of the sovereign. (2) Envoyos, ministers, or other persons accredited to sovereigns. (3) Ministers resident, accredited to sovereigns. (4) Charges d'affaires, accredited to ministers for foreign affairs.

Yet more remarkable as an act of legislative aspect was the declaration on maritime law made by the Congress of Paris of 1856. The declaration embraced four rules:

- (1) Privateering is and remains abolished.
- (2) The neutral flag covers an enemy's goods, with the exception of contraband of war.

(3) Neutral goods, with the exception of contraband of war, are not liable to capture under the enemy's flag.

(4) Blockades, in order to be binding, must be effective, that is to say, maintained by a force sufficient really to prevent access to the coast of the enemy.

The fourth rule may, as has heretofore been observed, be considered as merely declaratory of international law; for publicists had ceased to defend the paper blockades of the Napoleonic era. The third rule may also be classed as declaratory, since it was generally observed in the absence of a treaty stipulation to the contrary. But by the first two rules it was proposed to give the character and force of law to principles which had previously been obligatory only where they were made so by express treaty. This element in the situation was acknowledged in the declaration itself, in which the signatories announced their purpose to invite the adhesion of other powers with a view "to establish a uniform rule." The powers invited to adhere embraced practically all those within the sphere of international law; and, with the exception of the United States, Spain, and Mexico, they accepted the declaration in its entirety. Those three powers objected to the naked inhibition of privateering on the ground that, so long as the maritime capture of private property was recognized as lawful warfare, such an inhibition would give undue advantage to great naval powers, but the United States offered to go further and accept the entire declaration, if it were so amended as to exempt private property at sea from capture, save in the cases of contraband and blockade. All the powers approved the second rule and it is now a principle of international law. It was so announced by the United States and Spain at the outbreak of the recent war between them.

Since 1860 numerous attempts have been made by means of international conferences to legislate on the modes of conducting warfare. On 22 Aug. 1864, there was concluded at Geneva the famous convention for the amelioration of the condition of the wounded in armies in the field, commonly called the Red Cross Convention. Almost all civilized powers have adhered to this convention, and the observance of its provisions is considered a test of civilization. Agreements and declarations have also been made as to the nature of the weapons that may be used in war, and as to the treatment of prisoners of war. In this relation we should specify the declaration of St. Petersburg of 1868, which was framed by an international military commission. Far more extensive, covering almost the whole field of the laws of war on land, is the project of declaration of the Brussels Conference of 1874, which, though the powers represented in the conference failed afterward to make it binding, forms the basis not only of the "Manual" formulated by the Institute of International Law in 1880, and of the plan of convention adopted by the Spanish-Portuguese-Latin-American Military Congress at Madrid in 1892, but also of The Hague Conference rules concerning the laws and usages of war.

Notice should also be taken, as contributions to the development of international law, of the efforts made in the 19th century, outside international conferences, to codify various branches of international law, and especially the laws of war. In this particular the 19th century should not withhold its tribute to the 17th, which, even though its earlier wars were distinguished by

INTERNATIONAL WORKINGMEN'S ASSOCIATION

barbarities, may yet claim as its own Gustavus Adolphus and his humane code. Nevertheless we find in the recent acts of various governments a marked advance toward a more comprehensive system. The publication by the United States in 1863 of instructions for the government of armies in the field set an example which has had a stimulating effect. In July 1870, ample instructions were issued by the French government to its naval officers. Russia in 1877, during the conflict with Turkey, issued to her soldiers a catechism founded on the project of the Brussels Conference, besides prescribing liberal rules for the treatment of prisoners of war. In 1894, after the outbreak of the war with China, Japan promulgated a comprehensive prize law, based on the works of jurists, the conclusions of the Institute of International Law in 1882, and the French naval instructions of 1870, and setting the salutary example of abolishing the interest of the individual captor in the prize. In the war between the United States and Spain, each belligerent issued systematic instructions for the government of its army and navy, and the secretary of the navy of the United States has since prescribed, with the President's approval, for the use of that branch of the service, a naval war code, which purports to embody the laws and usages of war at sea.

In the recent development of international law, much influence has no doubt been exerted by unofficial societies, the activity of which specially marked the second half of the 19th century. In the case of the Red Cross Convention, the original impulse proceeded from such an association. The Institute of International Law (*Institut de Droit International*), and the International Law Association, formerly known as the Association for the Reform and Codification of the Law of Nations, are leading examples of societies, unofficial in constitution but international in membership, which are devoted to legal progress.

Besides improving the general rules of law, nations have during the past 100 years made great progress in securing by cooperation common interests, the attainment of which can be assured only by special agreements. The tendency toward cooperation may be seen in the treaties, of which the convention signed at Brussels 2 July 1890, may be mentioned as the leading example, made for the purpose of putting an end to the African slave trade. It may also be observed in the adoption, as the result of the Marine Conference at Washington, in 1889-90, of uniform rules of navigation.

In 1883 a number of powers of Europe and America entered into an international union for the protection of industrial property, and various governments which were not among the original parties have since adhered to it. In the following year a convention was made between 26 states for the protection of submarine cables outside territorial waters. Only two years later, on 9 Sept. 1886, a treaty was concluded at Berne for the protection of property in literary and artistic work. To this treaty, commonly called the International Copyright Convention, the United States was not a party; but it may be said that a step toward its acceptance was taken in the act of Congress of 1891, by which foreign authors and artists were for the first time enabled, subject, however, to the limitation of having the type set in the United States, to copyright their

works in the United States as well as at home. One should also mention the various international agreements in recent times for the regulation and protection of fisheries on the high seas.

By the process of national consolidation which specially marks the more recent years, international relations have been profoundly affected. Multitudes of petty states, with diverse interests and claims to distinction, have been absorbed into great national organizations. If international relations have not, in consequence of this absorption, lost any of their seriousness and importance, they have in a sense become more simple, and the possibilities of international cooperation, whether for the improvement of law or the protection of common interests, have increased. But while the situation has thus been simplified, there has also been a significant widening of the circle in which are included the states that acknowledge the obligations and enjoy the advantages of international law. As the law of nations was originally the product of the Christian states of Europe, nations were classified, with reference to its acceptance and rejection, as Christian and non-Christian. With the admission of Turkey, by the Treaty of Paris of 1856, "to participate in the advantages of the public law and concert of Europe," this classification ceased to be accurate. Lately we have witnessed a further enlargement of the circle by the admission of Japan. The admission of those states to the concert of nations does not signify that the standards of international law have been altered or abandoned. On the contrary it denotes a more general acceptance of those standards as the test of advancement in law, in morals, and in civilization. See DIPLOMACY; HAGUE CONFERENCE; NEUTRALITY.

International Peace Conference. See HAGUE CONFERENCE.

International Workingmen's Association, an organization of the workingmen of all countries for the advancement of the interests of labor and the emancipation of the working classes. It grew out of a visit of French workingmen to the World's Exposition at London in 1862. In 1864 an organization was formed in London, and an 'Address and Provisional Rules' published; the rules provided for a general congress to be held annually and a central council appointed by that congress to sit in London; workingmen's societies were to join the International in their corporate capacity. The principles and policy were not then definitely announced; the first congress held at Geneva in 1866 passed resolutions favoring the limitation of the working day and the abolishing of child labor; at the next congress at Lausanne (1867) socialistic principles were first definitely announced; from this time the influence of Marx and his followers grew in the organization. In 1868 at the Brussels congress the International announced its opposition to war, and favored the general strike; at the Basel congress in 1869 Bakunin and the anarchists were admitted; but they were expelled from the association in 1872 at the congress at The Hague; this same congress transferred the seat of the General Council to New York. The anarchists held a separate congress at Ge-

INTERSTATE COMMERCE COMMISSION—INTESTINE

neva in 1873. In 1867 the International rendered substantial aid to the strike of the bronze workers in Paris, and the next year to the strike of the Geneva builders; it assisted the English workmen by preventing the importation of underpaid laborers from the Continent in time of strikes. The International was accused of complicity in the Paris Commune, and while the two had no official connection many of the leaders of the Commune were Internationalists, and its principles and aims were defended by the International. In the United States the Socialist Party, a socialist political organization, was affiliated with the International in 1868, and later some individual trades-unions were also affiliated; finally the North American Federation of the International was formed and held its first national congress in 1872; its organization was in local sections of at least ten members, with a Federal Council of nine elected by the annual congress. Shortly after the transfer of the General Council to New York the Internationalists took a prominent part in the eight-hour day demonstration in New York. The formal organization of the International was dissolved in 1875; in Europe the Social Democratic parties of the different countries grew out of it, and in the United States the Socialist-Labor party. The anarchist faction in the United States split into two organizations, the International Workingmen's Association and the International Working People's Association. The International was important in the history of the labor movement as being the first expression of the recognition of the common interests of labor in all countries, and as being the means of spreading widely the knowledge of the principles of the Marxian socialism. Interval, in music, is the distance or difference of pitch, arithmetically expressed, between any two tones of a given scale. Occidental nations, including America, employ the diatonic scale (see **SCALE**), an octave comprising five tones and seven semitones, named after the first seven letters of the alphabet. The affix of a flat or sharp before a note denotes its quality but does not affect its name, and the eighth note being in unison commences a new octave. Taking the scale in the key of C major, the various intervals are: minor second = E-F or B-C; grave major second = C-D, F-G, A-B; grave minor third = D-F; minor third = E-G, A-C, B-D; major third = C-E, F-A, or G-B; perfect fourth = C-F, D-G, E-A, G-C', or B-E'; acute fourth = A-D'; acute augmented fourth = B-F; grave diminished fifth = B-F'; grave fifth = D-A; perfect fifth = C-G, E-B, F-C', G-D', A-E; minor sixth = E-C', A-F-B-G'; major sixth = C-A, D-B, G-E'; acute major sixth = F-D'; grave minor seventh = D-C', G-F', B-A'; minor seventh = E-D', A-G; seventh = C-B, F-E'; octave = C-C', D-D', etc. By taking various notes of the diatonic scale as starting points, and measuring known intervals from these, we arrive at inter-

mediate notes of the scale, of which the following are examples: C# minor third below E; D# minor second below E; E $\frac{1}{2}$ minor third above C; A $\frac{1}{2}$ minor sixth above C; B $\frac{1}{2}$ minor seventh above C; B $\frac{1}{2}$ 3 major third above C. The difference of pitch between C and C# or between D and D $\frac{1}{2}$ is called a semitone, and an interval increased or diminished by a semitone is said to be augmented or diminished. This applies especially to the interval of a fourth or a fifth, which with the octave are said to be perfect, because any augmentation or diminution mars their consonance. The major sixth or third may, however, be diminished to a "minor" sixth or third without destroying the consonance; and the term "minor" is also applied to the diminished second or seventh. Intervals confined within the octave are simple, when they exceed it compound; the octave beginning a new series, the ninth is the octave of the second, and so forth.

Intestacy, the legal state of a person dying without having disposed of his property by last will and testament. In Great Britain intestacy does not affect real estate, which is disposed of in accordance with the rule of descent. The effect of intestacy in Great Britain is merely that no directions have been left for the distribution of personal property. The effect of intestacy in the United States varies in accordance with the laws of inheritance fixed by each of them. Intestacy may be complete, as when a valid will is not left by the dead proprietor; or partial, when the extant will only provides for the distribution of part of the property. In these cases the property passes to the heirs or next of kin of the decedent in accordance with the laws of the place where the property is. See **DESCENT; HEIR; INHERITANCE.**

Intestine, Bowel, or Gut, the alimentary tube, in the higher animals limited to that portion between the stomach and the outlet at the anus. The human intestine is divided into the small and large intestine, the two parts varying in structure, movement, and function. The small intestine starts at the pylorus of the stomach, as the duodenum, and the first eight or ten inches are so distinguished. This portion is the widest and most deeply placed of the parts of the small intestine. About three or four inches below the pylorus the ducts of the gall-bladder and pancreas open conjointly into the bowel. The duodenum emerges from the cover of the peritoneum and becomes the jejunum. The remainder of the small intestine constitutes the jejunum (about two fifths) and the ileum. Between these divisions there is little difference, except that the jejunum is more freely movable, occupies the upper left portion of the abdomen more than the lower and right, and has thicker walls. The lumen of the small intestine gradually grows less from the duodenum, where it is two inches and a half in diameter, to little more than an inch where the ileum empties into the large intestine. The ileum is inserted several inches above the actual beginning of the large intestine, so that a blind pouch is formed below the point of juncture; this pouch, called the cæcum, gives off the appendix vermiformis (see **APPENDICITIS**) from its lower and back part. From the cæcum the large bowel passes up to the under surface of the liver as the ascending colon (see **COLON**), thence across the abdomen

INTESTINE

below the lower border of the stomach as the transverse colon, turns down to the iliac fossa as the descending colon, forms a peculiar S-shaped curve, the sigmoid flexure, which passes over the brim of the pelvis, where it is called the rectum (q.v.). The large bowel is about six feet in length. Both bowels have four coats, the mucous coat, the submucous, the muscular, and over most of the bowel an investment of peritoneum forming the serous coat. In the small intestine the mucous membrane is thrown up into permanent folds, each extending over half-way around the inside of the bowel. In this way a large surface is exposed for the absorption of food. Furthermore, the inner surface is covered with finger-like projections called villi, each having a large absorbing vessel in its centre. At the bases of the villi are tubular (of Lieberkühn) and branching glands (of Brun-

Section of the Ileum and Cæcum: *a*, ileum; *b*, cæcum; *c*, ileocecal valve; *d*, opening of the appendix; *e*, appendix.

ner) that dip down into the mucous membrane. Scattered over the surface there are tiny collections of lymphoid tissue, called solitary follicles, and here and there collections of these follicles into groups one to three inches long, called Peyer's patches. It is these spots that are attacked and ulcerated in typhoid fever. The muscular coat consists in an inner layer running around the bowel and an outer longitudinal coat. The large bowel differs from the small in the absence of the folds and villi, and is but slightly movable within the abdomen, being bound down to the abdominal wall posteriorly by the peritoneum. (See PHYSIOLOGY.)

Diseases of the Intestine.—These may be disturbances of the function of the bowels without actual inflammation, or they may be inflammations in different parts and of different kinds; but with inflammations there is necessarily a disturbance of the various functions, and differentiation frequently becomes a matter of difficulty. Diarrhoea and constipation (q.v.)

are symptoms of many different conditions, as are also deficiencies of secretion and absorption. The nervous mechanism of the bowels may be changed, giving rise to abnormal sensations and disturbance of all the functions. True inflammation of the intestines is the most common cause of abnormal action, and therefore is described in detail.

Acute Intestinal Catarrh is an inflammation of the mucous membrane that varies much in its symptomatology with the part of the bowel affected and the causative agent. Among the causes may be mentioned the eating of tainted fruits and other foods; the overeating of any food; overdrinking, particularly of very cold liquids; the ingestion of chemical or mechanical irritants; "catching cold"; and the poisons of the infectious diseases. The bowel is inhabited by numerous forms of micro-organisms, many of which are entirely harmless; but when any of the various agencies mentioned above affect the mucous membrane, the micro-organisms are able to attack the damaged surface. Many forms of bacteria produce particular types of disease when they find such lodgment, because they invade the system with their peculiar products. (See CHOLERA INFANTUM; CHOLERA; DYSENTERY.) But to the growth of bacteria must always be ascribed some of the symptoms in any intestinal catarrh. The attack usually starts in acutely with fever, general bodily discomfort, and abdominal pain. If the inflammation be confined to the upper part of the small intestine there may be constipation; but this is uncommon, and diarrhoea is the rule. Inflammation of the small intestine is spoken of as enteritis, but this is usually associated with more or less inflammation of the large bowel, called colitis (q.v.), although it may occur alone even in its last portion, the rectum. The pain in colitis is apt to be confined to the sides of the abdomen, and when the inflammation is low down there is constant desire to defecate, pain accompanying the act. Passage of mucus alone also indicates an inflammation low down in the rectum. The stools in acute intestinal catarrh vary much with the cause of the trouble; in some observed cases of dysentery the discharges are like rice-water. Treatment of these conditions depends upon the severity and location of the inflammation. The mild cases, with ordinary loose movements, recover without medication with abstinence from food for 24 hours. Castor-oil or small doses of calomel will cleanse the intestine of irritating substances. The more severe cases are kept in bed and allowed small amounts of milk after the first day, and are given small doses of castor-oil or mixtures of bismuth, opium, and other sedative drugs. If the large intestine is found to be involved, irrigation with common salt in water (teaspoonful to the quart) is valuable. Great care must be used in the selection of diet for some time.

Duodenitis occurs associated with acute gastritis (q.v.), and has the same symptoms, except for the presence of jaundice due to the closure of the bile-ducts. The disease runs its course ordinarily in a few weeks without any treatment except rest in bed for a few days, simple diet, and mild cathartics to relieve the constipation. *Chronic intestinal catarrh* results from a severe attack of acute inflammation in which the mucous membrane is left with permanent changes, or from repeated attacks of inflammation. Cases

INTESTINE

of chronic inflammation may occur without previous evidence of acute attacks. The symptoms vary much in kind and intensity, but pain, flatulence, and disturbance of the bowels are usually complained of. There may be pronounced constipation, alternating constipation and diarrhoea, daily unformed movements not distinctly diarrhoeal, or, what is most common, a constant diarrhoea. More or less admixture of mucus in the stools is usually observed. Sooner or later there is apt to be a loss of flesh and strength. When the large bowel is much involved in such a process there is usually a coating of the stools with mucus, or the passage of clear mucus.

In the treatment it is best to rely mainly on carefully regulated life—exercise, baths, fresh air, sufficient rest, avoidance of exposure, and properly selected diet. In diet the objects sought are the regulation of the bowels and the avoidance of irritation. When there is diarrhoea it is wise to avoid fruits, salads, cabbage, coarse-fibred breads, sugars, honey, pastry, sour and sweet wines, and carbonic beverages. In cases attended with constipation most of these may be allowed, but sausages, rich dressings, cucumbers, cabbage, and very coarse-fibred breads should be forbidden. Mineral waters are frequently used with success, such springs as Carlsbad and Vichy for the diarrhoeal cases, and such as Marienbad, Hathorn, and Congress for those attended with constipation. Chronic catarrh of the large bowel is treated with small doses of castor-oil and irrigations of the bowel with water, to which may be added antiseptics or astringents.

Intestinal Hemorrhage, or blood passed from the bowel, may be due to piles, tumors, dysentery, colitis, typhoid fever, tuberculosis of the intestinal tract, ulcers of the duodenum, portal obstruction as in cirrhosis of the liver, haemophilia, purpura, and the hemorrhagic forms of the infectious diseases. When blood coming from the stomach or high up in the small intestine is passed by rectum it is changed to a tarry appearance. This is due to the action of the digestive juices and bacteria. The farther down the intestine the blood starts, the brighter red is it found when passed.

Intestinal Obstruction.—This is a term that includes a great variety of conditions in the abdomen having the common feature of obstruction to the passage of the contents along the bowel; and in addition there is in the acute condition some injury to the bowel resulting in special symptoms. Two varieties are differentiated, the acute and the chronic. Acute intestinal obstructions are caused by foreign bodies, gall-stones, and hardened or large collections of faeces in the canal; by contracting scars, or tumors of the wall, twists of the gut (volvulus), intussusceptions (invagination of a portion above into the part below); by adhesions of the peritoneum, causing constricting bands; and by strangulations of portions of the bowel contained in hernia. Besides these causes, from local or general peritonitis there is apt to be a condition of paralysis of a portion of the bowel, giving rise to the same state. The symptoms vary considerably with the cause of the obstruction and the part of the bowel affected, but in general the symptoms are pain—frequently of a colicky sort—constipation, inability to pass gas—with resulting tympanites—vomiting, first from the shock, and later from

reversed peristalsis, until at length the vomitus is bilious and finally even faecal. Because of these symptoms and the injury to the nerves of the intestine resulting in "shock," there is a gradually increasing prostration. Certain features indicating that the obstruction is in the small intestine are early vomiting, the passage of faeces from the lower bowel, and the greater swelling of the centre of the abdomen. Absolute constipation from the first is apt to mean an obstruction low down in the large bowel. The cause of the obstruction may be indicated by the presence of a tumor, or by something in the previous history. Intussusception is the most common cause of the obstruction in children; a tumor may be felt on the outside, or the bowel may be felt in the rectum. Faecal impaction is indicated by a long history of constipation, and rectal examination shows the hardened masses. If intestinal obstruction be not relieved, the patient may die of shock, with gradual exhaustion, from gangrene of the bowel—the blood-supply being usually shut off—and sometimes from peritonitis.

Medical measures for the relief of most forms of the malady are not successful, and temporizing is attended with danger; but rest of the body as a whole, and especially of the intestinal tract, must be absolute. Some authorities advise the use of opium for further quieting the intestine when the diagnosis is certain. Lavage of the stomach is of great value, and large enemas may be curative when the cause of the trouble is intussusception, foreign body, or hardened faeces. Most forms of obstruction require the opening of the abdomen, search for the cause of the obstruction, and attempts at removal. Results depend on the quickness with which operation is undertaken; death may ensue, in spite of the removal of the obstruction, if interference be too long postponed. Chronic intestinal obstruction is caused by about the same conditions as the acute variety. The symptoms include various digestive disturbances, flatulence, constipation, and, when due to malignant growths, the general loss of flesh and strength.

Intestinal Parasites.—Three principal forms of these affect man—tapeworms, roundworms, and pinworms (qq.v.) The list of symptoms attributed to the presence of tapeworms in the human intestine is long and varied, but even loss of nutrition from such a parasite's presence is usually slight. Finding the worms or their eggs in the stools is the only convincing symptom. Treatment of this condition consists first in the preparation of the intestine by light diet for 24 hours before the taenifuge is given and six or eight hours before, allowing a liberal diet of onions, salty herring, and garlic; this rather loosens the worm's hold. Mild purgatives may also be given at this time. Early on the following morning the selected drug is taken, and this may be either male-fern, pomegranate, pumpkin-seed, kousso, or kamala. After about 12 hours a brisk cathartic is taken and the worm is passed. Careful search must be made for the head, for unless it is passed treatment must be started again while the worm is yet weak. Santonin and purgatives effect expulsion of roundworms. In the treatment of pinworms it is customary to take advantage of the fact that the females deposit their eggs in the large intestine and rectum. Santonin

INTONING—INVENTIONS

and cathartics aid in gathering the worms where they may be killed by injections of benzine (20 drops to the pint of water), or by solutions of quinine, though further catharsis may be necessary.

Brooklyn, N. Y.

Inton'ing, the practice of delivering prayers in the recitative form. Intoning differs little from chanting: in the latter case the cadence is more developed, the divisions more rhythmical, and the music in continuous harmony. In intoning the greater part of the prayer is recited on one note, and then sung by several voices in unison, the closing words of the sentence being sung to the proximate notes of the scale and in harmony. The practice of intoning prevails in the Greek, Roman, Anglican, and Lutheran Churches.

Intoxica'tion (literally poisoning, commonly restricted to poisoning by means of alcohol, for a discussion of which latter see ALCOHOLISM). Intoxication in the sense of poisoning may result from poisons having their origin outside of the human body (exogenous poisoning), or from poisons which may be developed within the body itself (endogenous poisoning, or auto-intoxication). Some of the most important problems connected with the infectious diseases concern themselves with the study of the intoxications that result from the formation of toxins by specific bacteria distributed throughout the human body during the course of a disease. From the same point of view many of the most complicated intoxications result from variations in the normal metabolism of the body. Thus in diabetes mellitus (q.v.) there is developed an acid intoxication (diabetic coma), which is due to the inability of the body properly to neutralize by its alkaline salts the excessive amounts of acid produced as a result of the perverted metabolism of this disease. Similarly in Bright's disease a type of intoxication (uræmic poisoning) results from failure of the kidneys to eliminate poisonous products from the human body. It seems not unlikely that a number of diseases such as migraine (sick headache), some forms of epileptic convulsions, different types of skin-eruptions, and some of the mild insanities result from auto-intoxication (q.v.). See POISONING.

Introduced Species. A long catalogue might be made of species of animals and plants which have been transferred by accident or design from their native country or locality to other regions. Sometimes, as in the case of salmon in New Zealand, rabbits in Australia, the European house-sparrow in America and elsewhere, or western fishes in eastern waters, this is done by design; but in the great majority of cases the introduction is accidental and unwelcome, as in the case of the hundred and more species of injurious insects brought into the United States from foreign lands (or the fewer sent abroad from here), and the very many species of "weeds" naturalized on our, and other shores. Such introductions are in the main accidental, the eggs or seeds or grown individuals passing from one region to another in ships or railway trains, or cargoes or discharged ballast; so many plants have been introduced by the latter means that botanists class the group of alien

weeds as "ballast plants." See ACCLIMATIZATION; ZOOGEOGRAPHY.

Intuba'tion, the introduction of a tube into an orifice or an organ, as the larynx, to keep it open. Specially designed tubes for such a purpose are sometimes used in cases of croup, diphtheritic obstruction, etc., as a substitute for tracheotomy.

In'u'lin, a substance resembling starch, but intermediate in nature between that body and the gums. It occurs in the roots of elecampane, dandelion, and certain other plants, and also in the Jerusalem artichoke and the common potato. When pure it is a tasteless white powder consisting of spherical particles. Its chemical formula is probably a multiple of $C_{10}H_{10}O_5$, though $C_7H_{12}O_2$ has been suggested. It is insoluble in alcohol, and but slightly soluble in cold water, although it is very hygroscopic. It dissolves freely in hot water. It melts at 320° F., becoming thereby converted into a different substance known as "pyro-inulin." It is not fermentable, and does not reduce Fehling's solution. Iodine renders it brown or yellow.

Invasion, the entry into a country by a public enemy. As early as 1795 Congress provided by law for protection against the invasion of the United States by any foreign nation or Indian tribe. The act made it lawful whenever there should be an invasion, or imminent danger of one, for the President to call out such number of the militia of the State or States convenient to the place of invasion as he might think necessary to repel it. This, strengthened in some respects by amendments, has been in force ever since. An invasion has usually all the elements of war, and the invaders may be dealt with as persons at war with the country invaded, in accordance with usages of warfare without the declaration of war by Congress. The Supreme Court of the United States has decided that a State is invaded when there is a domestic rebellion within its territory, and that the same rules of law may be enforced as in the case of an invasion by external foes. This decision practically abolishes all distinction between invasion and insurrection, and the same rules which furnish a remedy for invasion can be applied in the suppression of an insurrection or local rebellion. In case the State militia is not sufficiently strong, or not easily available, the standing troops of the United States may be ordered out by the President, if indeed it be necessary to call upon the State troops before resorting to the regular troops of the United States. It is not necessary that actual armed violence shall be resorted to in order to constitute insurrection. Any combination of persons too powerful to be suppressed by the ordinary course of judicial proceedings is tantamount to insurrection, and warrants the use of the effective measures provided for by law for its suppression.

Inventions. The progress of the world in its numerous vast industries and arts has been founded, to a very large extent, upon inventions and discoveries and their subsequent development. Under the American patent law and system, inventors all over the world are stimulated to make public their inventions by reason of receiving in exchange a monopoly in the form of a patent on the invention for a

INVENTIONS

period of 17 years. The remarkable increase in the number of protected inventions is shown by the records of the United States Patent Office, as follows: At the end of the first year (1790) 3 patents were issued. In the year ending 1902, 27,136 patents were granted. The total number of patents issued from April 1790 to November 1903 was 752,774.

An invention is recognized to be any new or useful mechanical contrivance or article, method, discovery, composition of matter, or system not previously known or used, or any improvement on any known machine, art, method, or system. Below is given in chronological order a list of important inventions beginning with the 16th century, with the title of the invention, the year it was made, the name of the inventor and his nativity:

INVENTIONS	Date	Inventor	Nativity	
Discoveries of Electrical Phenomena... Won the title of "founder of the science of electricity."	{ 1560 1603	William Gilbert	England	
Screw printing-press.	1620	Blaew	Germany	
Spirally grooved rifle barrel.....	1620	Koster	England	
Iron furnaces.....	1621	Lord Dudley	England	
The use of steam.... The first authentic reference in English literature to the use of steam in the arts.	1630	David Ramseye	England	
Bay Psalm Book, first book published in the Colonies.... Barometer	1640		Mass.	
Steam engine, atmospheric pressure	1643	Torricelli	Italy	
Machine for generating electricity.....	1663	Thomas Newcomen	England	
First paper mill in America	1681-6	Otto von Guericke	Germany	
First steam engine with a piston.....	1690	William Rittenhouse	Penna.	
The manufacture of plate glass established.....	1690	Denys Papin	France	
First to discover difference between electric conductors and insulators....	1695		France	
The first practical application of the steam engine.....	1696	Stephen Gray	England	
First newspaper in America "Boston News Letter".....	1702	Thomas Savery	England	
First to produce electric spark.....	1704	John Campbell	Mass.	
Thermometer	1708			
Electrometer, the well known pith ball.....	1716	Dr. J. Wall	England	
Thermometer	1709	Fahrenheit	Danzig	
Printing-press	1718			
Electrical glass plate machine	1725	John Cantor	England	
Stereotyping	1727	Benjamin Franklin	Utd. States	
First to discover that electricity is of two kinds	1733-9	Martin de Planta	France	
Flying shuttle in weaving	1733	William Ged	Scotland	
Rotary 3-color printing-press (Multi-Color)	1743	Cisternay Fay	France	
Electric or Leyden Jar Substitution of coke for coal in melting iron	1745	John Kay	England	
Lightning conductor.....	1750	Abraham Darby	England	
Spinning jenny	1752	Benjamin Franklin	Utd. States	
	1763	James Greaves	England	
Piano forte, played in public in England in	1767	Richard Wright	Ark.	England
Drawing rolls in a spinning machine.....	1769			England
The introduction of the "Hollander" or beating engine for pulping rags in the manufacture of paper	1773	Samuel Cramp-ton		
The mule spinner.....	1774	Jeremiah Wilkinson		England
Cut nails.....	1775	Miller		Utd. States
Circular wood saw.....	1777	Branchard & Magurier		England
Embryo bicycle.....	1779			France
Steam engine, the basis of the modern engine	1782	James Watt		Scotland
Gas balloon	1783	J. E. & J. M. Montgolfier		France
Puddling iron	1783-4	Henry Cort		England
Plow, with cast iron mold board, and wrought and cast iron shares.....	1784	James Small		Scotland
Power loom.....	1785	James Cartwright		England
First steam-boat in the United States.....	1786	John Fitch		Utd. States
Steam road wagon... (First automobile).	1787	Oliver Evans		Utd. States
Grain thrashing machine	1788	Andrew Meikle		England
Uranium discovered.....	1789	Klaproth		Germany
Hobby-horse, forerunner of bicycle.....	1790			England
Rotary steam power printing-press, the first idea of.....	1790	Wm. Nicholson		
Wood planing machine	1791	Samuel Bentham		England
Gas first used as an illuminant	1792	Wm. Murdoch		England
Cotton gin.....	1794	Eli Whitney		Utd. States
Art of Lithography.....	1796	Alois Senefelder		Germany
Machine for making continuous webs of paper.....	1800	Louis Robert		France
Steam coach	1801	Richard Trevithick		England
Wood Mortising Machine	1801	M. J. Brunel		England
Pattern loom	1801	M. J. Jacquard		France
First fire proof safe.....	1801	Richard Scott		England
Steamboat on the Clyde, "Charlotte Dundas"	1802	William Symington		England
First photographic experiments	1802	Wedgewood & Davy		England
Planing machine.....	1803	J. Branch		England
The application of steam to the loom	1803	William Horrocks		England
Steel pen.....	1803	Wise		England
Steam Locomotive on rails	1804	Richard Trevithick		England
Application of twin screw propellers in steam navigation	1804	John Stevens		Utd. States
Process of making malleable iron castings	1804			
First life preserver.....	1805	Lucas		England
	1805	John Edwards		England
Electro-plating	1805	Luigi Brugnelli		Italy
Knitting machine, the latch needle in the Steamboat navigation on the Hudson River	1806	Jeandean		France
Percussion or detonating compound	1807	Robert Fulton		Utd. States
First street gas lighting in England	1807	A. J. Forsyth		Scotland
Band wood saw	1807	F. A. Winsor		England
Barium, strontium and calcium	1808	Newberry		England
Polarization of light from reflection.....	1808	Sir Humphry Davy		England
	1808	E. L. Malus		France

INVENTIONS

INVENTIONS	Date	Inventor	Nativity	INVENTIONS	Date	Inventor	Nativity
Voltaic arc.....	1808	Sir Humphry Davy	England	Wood planing machine	1828	William Woodworth	Utd. States
First steamboat to make a trip to sea, the "Phoenix"....	1808	John Stevens S. C. F. Hahne-mann	Utd. States	Tubular locomotive boiler	1828	Séquin	France
Homeopathy introduced	1810	Frederick Koenig	Germany	Prism for polarized light	1828	Nicol	England
Revolving cylinder printing-press	1810	Thornton & Hall	Utd. States	Spinning ring frame	1828	John Thorp	England
Breech-loading shot-gun	1811	J. B. Ritter	Germany	The "Washington" printing press, lever motion and knuckle joint for a screw, number of impressions per hour, 200	1829	Samuel Rust	Utd. States
Storage battery.....	1812	Zamboni		First steam locomotive in United States, "Stourbridge Lion".....	1829		
Dry Pile (prototype of dry battery)....	1812			Double fluid galvanic battery	1829	A. C. Becquerel	France
First practical steam rotary printing press, paper printed on both sides.....	1814	Frederick Koenig	Germany	Magnesium	1829	Adam Bussey	France
First locomotive in Scotland	1814	George Stephenson	England	First portable steam fire engine	1830	Brathwaite & Ericsson	England
First circular wood saw made in this country	1814	Benjamin Cummings	Utd. States	Magneto-electric induction	1831	Michael Faraday	England
Heliography	1814	Jos. N. Niepce	France	Chloroform	1831	G. J. Guthrie	Scotland
Discovery of Cyanogen	1814	Gay Lussac	France	First conception of electric telegraph	1832	Prof. S. F. B. Morse	Utd. States
Kaleidoscope	1814	Sir David Brewster	England	First Magneto-electric machines	1832	Saxton	Utd. States
Miner's safety lamp..	1815	Sir Humphry Davy	England	Rotary electric motor	1832	Wm. Sturgeon	England
Serditz powder.....	1815			Chloral-hydrate	1832	Justus von Liebig	Germany
Dry gas meter.....	1815	S. Clegg	England	Locomotive, "Old Ironsides" built	1832	M. W. Baldwin	Utd. States
Morphine, first organic alkaloid known....	1816	Sertürner	Germany	Link-motion for locomotives	1832	Sir Henry James	England
Knitting machine....	1816	Brunel	England	Adoption of steam whistle for locomotives	1833	George Stephenson	England
"Draisine" bicycle, "Columbian" press, elbowed pulling bar, number of impressions per hour, 50	1816	Baron von Drais	Germany	Reciprocating saw-tooth cutter within double guard fingers for reapers	1833		
Stethoscope	1817	George Clymer Laennec	Utd. States France	"McCormick" reaper	1833	Obed Hussey	Utd. States
Electro - magnetism discovered	1819	H. C. Oersted	Germany	Rotary electric motor	1834	Cyrus H. McCormick	Utd. States
Lathe for turning irregular wood forms	1819	Thomas Blanchard	Utd. States	Carbolic acid discovered	1834	M. H. Jacobi	Russia
The theory of electro-dynamics first propounded	1820	Andre Ampère	France	Horse shoe machine	1834	Runge	Germany
Quinine	1820	Pelletier & Caventon	France	Constant electric battery	1835	H. Burden	Utd. States
Electroscope	1820	Bohnenberg	Germany	Acetylene gas discovered	1836	J. P. Daniell	England
The conversion of the electric current into mechanical motion	1821	Michael Faraday	England	The revolver; a device "for combining a number of long barrels so as to rotate upon a spindle by the act of cocking the hammer."	1836	Edmund Davy	England
Galvanometer	1822	Schweigger	Germany	The screw applied to steam navigation	1836	Samuel Colt	Utd. States
Multi-color printing.....	1822	P. Force	Utd. States	The galvanizing of iron	1841	John Ericsson	Utd. States
Calculating machine.....	1822	Charles Babbage	England	Indicator-telegraph	1837	Henry Craufurd Cooke & Wheatstone	England
Silicon	1823	James Berzelius	Switzerl'd	Photographic carbon printing	1837		
Discovery of thermo-electricity.....	1823	Prof. Seebeck	England	Babbitt metal	1838	Mungo Ponton	France
Liquefaction and solidification of gas.	1823	Michael Faraday	England	Vulcanization of rubber	1839	Isaac Babbit	Utd. States
Water gas, production of.....	1823	Ibbetson	England	The first boat electrically propelled	1839	Charles Goodyear	Utd. States
Portland cement.....	1825	Joseph Aspdin	England	Daguerreotype	1839	Jacobi	Germany
First passenger railway, opened between Stockton and Darlington, England	1825			First to produce a direct photographic positive in the camera by means of highly polished silver surfaced plate exposed to the vapors of iodine and subsequent development with mercury vapor.			
Electrical spur wheel	1826	Barlow	England	Making photo-prints from paper negatives	1839	Louis Daguerre	France
Bromine	1826	M. Baland	France	(First production of positive proofs from negatives).	1839	Fox Talbot	England
First railroad in United States, near Quincy, Mass....	1826						
The law of galvanic circuits formulated	1827	George S. Ohm	Germany				
Fraction matches....	1827	John Walker	Utd. States				
The reduction of aluminium	1827	Friedrich Wohler	Germany				
Law of electrical resistance	1827	George S. Ohm	Germany				
Improved rotary printing-press London Times, 5,000 impressions per hour	1827	Cowper & Applegarth	England				
Hot air blast for iron furnaces	1828	J. B. Neilson	Scotland				

INVENTIONS

INVENTIONS	Date	Inventor	Nativity	INVENTIONS	Date	Inventor	Nativity
Photographic portraits. (Daguerreotype Process)....	1839	Profs. Draper & Morse	Utd. States	Cocaine	1855	Gaedke	Germany
pneumatic Caissons....	1841	M. Triger	France	Process of making steel, blowing air through molten pig-iron	1855	Sir Henry Bessemer	England
Pianoforte automatically played.....	1842	M. Seytre	France	Dryplate photography	1855	Dr. J. M. Tuppenot	France
Steam hammer.....	1842	James Nasmyth	Scotland	Bicycle	1856	Ernest Michaux	Utd. States
Typewriting machine	1843	Charles Thurber	Utd. States	Sleeping car.....	1856	Woodruff Perkins	England
First telegram sent....	1844	Prof. S. F. B. Morse	Utd. States	Aniline dyes	1856		
The use of nitrous oxide gas as an anaesthetic	1844	Dr. Horace Wells	Utd. States	Printing machine for the Blind (contains elements of the present typewriting machine)	1856	Alfred E. Beach	Utd. States
The electric arc light (gas retort carbon in a vacuum)....	1844	Léon Foucault	France	Regenerative furnace	1856	Wm. Siemens	England
Automatic adjustment of electric arc light carbons	1845	Thomas Wright	England	Refining engine in paper pulp making	1856	T. Kingsland	Utd. States
Double cylinder printing-press	1845	R. Hoe & Co.	Utd. States	Coal-oil first sold in the United States..	1857	Messrs. Stout & Hand	Utd. States
Pneumatic tire.....	1845	R. W. Thompson	England	First sea going iron-clad war vessel the "Gloire"	1857		
Sewing machine	1846	Elias Howe	Utd. States	Ground wood pulp...	1858	Henry Voelter	Germany
Suez canal started....	1846	De Lesseps	France	Inclined elevator and platform in the reaper	1858	J. S. Marsh	Utd. States
Ether as an anaesthetic	1846	Dr. Morton	Utd. States	Cable car.....	1858	E. A. Gardner	Utd. States
Artificial limbs.....	1846	Schönbein	Germany	Breech loading ordnance	1858	Wright & Gould	Utd. States
Gun cotton.....	1846	Debain	France	Feed injector for Boilers	1858	Giffard	France
First pianoforte keyboard player	1846	Dr. Simpson	Scotland	Storage or secondary battery	1860	Gaston Planté	France
Chloroform in surgery	1847	Sobrero	Utd. States	Singing telephone	1860	Philip Reis	Germany
Nitro-glycerine	1847	Savage	Utd. States	Ammonia absorption ice machine.....	1860	F. P. E. Carré	France
Time-lock	1847	Richard M. Hoe	Utd. States	Improved stereotyping process	1861	Charles Craske	Utd. States
Hoe's lightning press capable of printing 20,000 impressions per hour.....	1847	A. L. Dennison	Utd. States	Shoe sewing machine	1861	George McKay	Utd. States
Match-making machinery	1848	Chambers	Utd. States	Driven well, a tube with a pointed perforated end driven into the ground...	1861	Col. N. W. Green	Utd. States
Breech gun-lock, interrupted thread.....	1849	Walter Hunt	Utd. States	Passenger elevator...	1861	E. G. Otis	Utd. States
Magazine gun.....	1849	Bourdon	France	Barbed wire fence introduced	1861		
Steam pressure gauge	1849	Sir David Brewster	England	Calcium carbide produced	1862	Frederich Wochler	Germany
Lenticular stereoscope	1849	J. T. Hibbert	Utd. States	Revolving turret for floating battery....	1862	Theodore Timby	Utd. States
Latch needle for knitting machine.....	1849	G. H. Corliss	Utd. States	First iron-clad steam battery, "Monitor"	1862	John Ericsson	Utd. States
"Corliss" Engine.....	1849	Jacob Worms	France	Gatling gun	1862	Dr. R. J. Gatling	Utd. States
Printing-press, curved plates secured to a rotating cylinder...	1849	John Mercer	England	Smokeless gunpowder	1862	J. F. E. Schultze	Prussia
Mercerized cotton.....	1850	Scott Archer	England	Pneumatic pianoforte player (regarded as first to strike keys by pneumatic pockets)	1863	M. Fourneaux	France
Collodion process in photography	1850	Dr. Page	Utd. States	Explosive gelatine...	1864	A. Nobel	France
American machine-made watches.....	1850	W. H. Seymour	Utd. States	Rubber dental plate.	1864	J. A. Cummings	Utd. States
Electric locomotive	1851	Maynard	Utd. States	Automatic grain binding device.....	1864	Jacob Behel	Utd. States
Self-raker for harvesters	1851	J. Gorrie	Utd. States	Process of making fine steel	1865	Martin	Utd. States
Breech loading rifle.....	1851	Rhumkorff	Germany	Antiseptic surgery ..	1865	Sir Joseph Lister	England
Ice-making machine.....	1851	Channing & Farmer	Utd. States	Web-feeding printing press	1865	William Bullock	Utd. States
The Rhumkorff coil	1852	Fox Talbot	England	Automatic shell ejector for revolver...	1865	W. C. Dodge	Utd. States
Fire-alarm telegraph. Reticulated screen for half-tone photographic printing	1852	Watt & Burgess	Utd. States	The Atlantic cable laid	1866	Cyrus W. Field	Utd. States
Soda process of making pulp from wood	1853	Michael Faraday	England	Open-hearth steel process	1866	Siemens-Martin	England
Laws of magnetoelectric induction.....	1853	Michael Faraday	England	Compressed air rock drill	1866	C. Burleigh	Utd. States
Laws of electrostatics	1853	Michael Faraday	Austria	Torpedo	1866	Whitehead	Utd. States
Electrolysis	1853	Gintl		Dynamo electric machine	1866	Wilde	England
Duplex telegraph....	1853	Melhuish	England	Sulphite process for making paper pulp from wood.....	1867	Tilghman	Utd. States
Photographic roll films	1854	Herman	Utd. States	Disappearing gun carriage	1868	Moncrief	England
Diamond rock drill.....	1854	A. B. Wilson	Utd. States	First practical type-writing machine.....	1868	C. L. Sholes	Utd. States
Four motion feed for sewing machines.....	1854	Smith & Wesson	Utd. States	Dynamite	1868	A. Nobel	France
Magazine firearm.....	1854	R. A. Tilghman	Utd. States	Oleomargarine	1868	H. Mege	France
Fat decomposed by water or steam at high temperature, since largely used in soap making....	1855	Lundstrom	Sweden				
Safety matches.....	1855						
Iron-clad floating batteries first used in Crimean war	1855						

INVENTIONS

INVENTIONS	Date	Inventor	Nativity	INVENTIONS	Date	Inventor	Nativity
Water heater for steam fire engine..	1868	W. A. Brickell	Utd. States	Rotary disk cultivator	1878	Mallon	Utd. States
Sulky plow.....	1868	B. Slusser	Utd. States	Decided advance in the " Expression " of self-playing pianofortes.....	1878	Gally	Utd. States
Railway air brake.....	1869	George Westinghouse	Utd. States	Automatic grain binder	1879	J. F. Appleby	Utd. States
Tunnel shield (operated by hydraulic power)	1869	Alfred E. Beach	Utd. States	Kathode rays discovered	1879	Sir Wm. Crookes	England
A curved spring tooth harrow	1869	David L. Garver	Utd. States	Steam plow	1879	W. Foy	Utd. States
Dynamo-electric machine	1870	Gramme	France	Magazine rifle	1879	Lee	Utd. States
Celluloid	1870	J. W. & Isaac Hyatt	Utd. States	" Blake " telephone transmitter	1880	Blake	Utd. States
Rebounding gun-lock	1870	L. Hailer	Utd. States	Hammerless gun.....	1880	Greener	Utd. States
The Goodyear welt shoe-sewing machine	1871	Goodyear	Utd. States	Storage battery or accumulator	1880	Camille A. Faure	France
Photographic gelatino bromide emulsion (Basis of present rapid photography). Continuous Web printing-press	1871	R. L. Maddox	England	Typhoid bacillus isolated	1880	Eberth & Koch	Germany
Grain binder	1871	Hoe & Tucker	Utd. States	Pneumonia bacillus isolated	1880	Sternberg	Utd. States
Compressed air rock drill	1871	S. D. Locke	Utd. States	Button hole machine	1881	Reece	Utd. States
Positive motion weaving loom	1872	S. Ingersoll	Utd. States	Improvement in " Expression " of self-playing pianofortes	1882	Schmaele	Utd. States
Theory that light is an electric phenomenon	1872	J. Lyall	Utd. States	Hand photographic camera for plates	1882	Wm. Schmid	Utd. States
Automatic air brake	1872	Clerk Maxwell	England	Tuberculosis bacillus isolated	1882	Robert Koch	Germany
Automatic car coupler	1873	George Westinghouse	Utd. States	Hydrophobia bacillus isolated	1882	Louis Pasteur	France
The photographic platinotype process Prints by this process are permanent.	1873	E. H. Janney	Utd. States	Cholera bacillus isolated	1884	Robert Koch	Germany
Quadruplex telegraph	1873	Willis	England	Diphtheria bacillus isolated	1884	Loeffler	Germany
Twine binder for harvesters	1873	T. A. Edison	Utd. States	Lockjaw bacillus isolated	1884	Nicolaier	France
Gelatino bromide photographic emulsion (Sensitivity to light greatly increased by the application of heat)..	1873	M. L. Gorham	Utd. States	Antipyrene	1884	Kuno	Utd. States
Self-binding reaper..	1873	Charles Bennett	England	Linotype machine	1884	Othmar Mergenthaler	Utd. States
Barbed wire machine	1873	Locke & Wood	Utd. States	The rear-driven chain safety bicycle	1884	George W. Marable	Utd. States
Siphon recorder for submarine telegraphs	1874	Glidden & Vaughan	Utd. States	Chrome tanning of leather	1884	Schultz	Utd. States
Store cash carrier..	1874	Sir William Thompson	England	Process of reducing aluminum	1885	Cowles	England
Illuminating water gas	1875	D. Brown	Utd. States	Gas burner	1885	Carl Weisbach	Germany
Roller flour mills	1875	T. S. C. Lowe	Utd. States	Hydraulic dredge	1885	Bowers	Utd. States
Middlings purifier for flour	1875	F. Wegmann	Utd. States	First electric railway in United States, Hampden and Baltimore, Md.....	1885		
Ice making machine	1875	Geo. T. Smith	Utd. States	Contact device for overhead electric trolley	1885	C. J. Van De poele	Utd. States
Speaking telephone..	1876	R. P. Pictet	Switzerl'd	Graphophone	1886	Bell & Tainter	Utd. States
Electric candle	1876	Graham Bell	Utd. States	Electric welding	1886	Elihu Thompson	Utd. States
(The first step towards the division of the electric current for lighting.)	1876	Paul Jablochko	Russia	Combined harvester and thresher	1886	Matteson	Utd. States
Continuous machine for making tobacco cigarettes	1876	Russell	Utd. States	Band wood saw	1887	D. C. Prescott	Utd. States
Steam feed saw mills	1876	D. C. Prescott	Utd. States	Cyanide process of obtaining gold and silver	1887	Mc Arthur & Forrest	Utd. States
The first Portland cement plant in U. S.	1876			System of polyphase electric currents	1887	Nicola Tesla	Utd. States
Phonograph	1877	T. A. Edison	Coplay, Pa.	I n c a n d e s c e n t g a s l i g h t	1887	Carl A. Von Weisbach	Austria
Gas engine.....	1877	N. A. Otto	Utd. States	The formation of a cone-shaped interwoven mantle of thread coated with a refractory rare earth and rendering the same incandescent by the heat rays of a Bunsen gas burner regardless of how the gas is produced

Method of rendering a clay compound capable of conducting electricity and thence becoming brilliantly incandescent without a vacuum.							
Radium discovered....	1898	Madame S. Curie	France				
Mercury vapor electric light	1900	Peter Cooper Hewitt	Utd. States				
An artificial light composed strictly of the ultra blue violet rays of the spectrum obtained by passing an electric current through a partial vacuum tube filled with mercury vapor, the latter acting as a conductor. Possesses remarkable actinic power for photographic purposes.							
Air-ship	1901	M. Santos-Dumont	France				
Automobile mower....	1901	Deering Harvester Co.	Utd. States				
The first passenger steam turbine ship, "Edward VII."...	1901	Denny & Brothers	England				

It is interesting to note that between the years 1872 and 1900 there were on what may be termed the honor roll of inventors 39 inventors each of whom had received over 100 patents. A few of the most important were:

Thomas A. Edison	742
Francis H. Richards	619
Elihu Thompson	444
Charles E. Scribner	374
Luther C. Crowell	293
Edward Weston	280
Rudolph M. Hunter	276
Charles J. Van Depoele (deceased)	245
George Westinghouse	239
Rudolph Eickemeyer (deceased)	171
Hiram S. Maxim	146
Philip Diehl	137
Hosea W. Libbey	127
Louis K. Johnson	114
Talbot C. Dexter	109
James H. Northrup	102

In the preparation of the foregoing statistics, credit is given to L H Campbell, of the United States Patent Office, for valuable assistance.

FREDERICK C. BEACH, Ph.B.

Editor 'The Scientific American.'

In'ventory, a written list or schedule of goods, chattels and other personal property of an individual or estate, whether for use in legal proceedings, or for commercial purposes. The term is also employed to designate lists of assets prepared in cases of insolvency and bankruptcy, and lists of property made out by guardians of estates or infants. These inventory lists are usually filed with the court for public examination. After an administrator or other officer of the court files his inventory he becomes personally accountable for the property or goods so listed. See also EXECUTOR.

Inver'sion, a change of order whereby the first becomes last and the last first. (1) In rhetoric, a reversal of the natural order of words for the sake of euphony, emphasis, or the like; also the turning of one's own argument against him by an opponent in discussion. (2) In chemistry, a change in molecular structure which is usually induced by fermentation or by heating with a dilute acid, as in the case of starch, sugar, etc. Thus starch and dextrine are changed into glucose, cane-sugar into invert sugar, and maltose into glucose. (3) In geology, the overturning or folding over of strata by igneous agency, so that the order of their succession seems reversed. (4) In mathematics, the operation of changing the order of the terms, so that the antecedent shall take the place of the consequent and the reverse, in both couplets. Thus, from the proportion $a : b : c : d$, we have, by inversion, $b : a : c : d$. (5) In music, the transposition of certain phrases having a common root. (a) The change of a chord by making one of the inner notes act as a bass note, by which means as many inversions can be made as there are actual notes in the chord, not counting the root, the

INVERTASE—INVOICE

harmony in such inversions remaining the same, though the order of component parts is changed; (b) alteration of intervals by making that which was the upper note the lower, and the reverse, the inversion of an interval within the octave being readily found in the difference between the figure 9 and the interval known; (c) the alteration of a subject produced by inverting the intervals of which it consists.

In'vertase, or In'vertin, an enzyme occurring in many fungi, notably in certain yeasts (for example, the *saccharomyces*), and also in the seed-plants. It transforms cane-sugar into a mixture of dextrose and levulose; this mixture being called "invert-sugar" because it turns the plane of polarized light to the left, while the cane-sugar from which it is obtained turns it to the right. According to some writers, a yeast cannot invert cane-sugar except by secreting invertase; but *Monilia candida* effects the inversion, and yet produces no invertase. In this case the action is probably due to some other enzyme, hitherto unidentified. Invertase probably plays a very important part in vegetable chemistry. Like other enzymes, it can apparently perform an unlimited amount of chemical work, without sensible diminution of its own substance. (See FERMENTATION.) Invertase is most active at a temperature of from 120° to 140° F., and in a slightly acid medium. It has been isolated in the form of a powder.

In'vertebrates, a collective term for the lower divisions or phyla of the animal series, which agree in not having a vertebral column or back-bone, used in contradistinction to the highest group of the animal kingdom, to which the name *Vertebrata* or vertebrate animals is given. In the system of Cuvier the *Invertebrata* were divided into the *Radiata*, *Articulata*, and *Mollusca*. Further study revealed that these names did not distinguish natural groups; and the term *Invertebrata* has no longer any definite significance in classification (q.v.).

In'vestiture, in the feudal law, was the open delivery of a feud by a lord to his vassal, thus, by external proof, affording evidence of property. To use the words of Blackstone, "Investitures, in their original rise, were probably intended to demonstrate, in conquered countries, the actual possession of the lord, and that he did not grant a bare litigious right, but a peaceable and firm possession. At a time when writing was seldom practised, a mere oral gift, at a distance from the spot that was given, was not likely to be long or accurately retained in the memory of by-standers, who were very little interested in the grant." For this reason investiture was performed by the presentation of some symbol to the person invested, as a branch of a tree, etc. In the primitive church, after the election of a bishop, and his consecration, the early Christian emperors claimed a right of confirmation. Charlemagne is said to have introduced this practice, and to have invested the newly consecrated bishop by placing a ring and crozier in his hands. Gratian, indeed (Distinct. 63, cap. Adrianus), directly affirms that Pope Adrian positively conceded to the emperor the power of electing, even to the papacy, in 774; but neither Egihard nor any other contemporary writer mentions this fact.

The custom, however, existed, nor does it

appear to have been objected to or opposed during the lapse of two centuries from his reign. The disorderly state of Italy, which succeeded the death of Charlemagne, frequently interrupted the exercise of this right by the Carlovingians; but even so late as 1047, when the empire had passed to another line, Henry III. received an explicit admission of his prerogative, and repeatedly used it. The investigation in the lesser sees followed as a matter of course. Alexander II. issued a decree against lay investiture in general, which was revived by Gregory VII. (Hildebrand), who, having succeeded in annulling the prerogative of the emperors to nominate or confirm popes, sought to disjoin entirely the ecclesiastical from the civil rule. It was not, however, until the papacy of Calixtus II., in 1122, that the question was terminated, as it appears, materially to the advantage of the holy see. In France, even under the papacy of Hildebrand, the right of investiture does not appear to have been made a subject of open quarrel. In spite of the protests of the holy see, the kings exercised the power, but at length relinquished the presentation of the ring and crozier, and contented themselves with conferring investiture by a written instrument, or orally, upon which they were left in peaceful possession of the power. But in England Paschal II. was engaged in a contest little less fierce than that which he maintained with the emperor. Anselm, the primate, refused to do homage to Henry I. for his see. The king seems to have asserted an unqualified right of vestiture, which the pope, who was appealed to, as unqualifiedly denied. After a protracted struggle, and continued threats of excommunication, the controversy ended in England, as it did afterward in Germany, by compromise. Paschal offered to concede the objections against homage provided Henry would forego the ceremony of investiture. To this he agreed (1107).

Invin'cibles, an Irish secret society of 1882, an off-shoot of the Fenians. One of the objects of the Invincibles was to "remove" or assassinate government officers or others who might incur the displeasures of the association or its leaders. On 6 May 1882 the society succeeded in "removing" Lord Frederick Cavendish, who had just arrived from England as secretary for Ireland, and Thomas A. Burke, the under-secretary, in the Phoenix Park at Dublin. The plot was directed against the latter gentleman, and the former, interfering to protect his friend, shared his fate. On 20 Feb. 1883 20 persons charged with complicity in the Phoenix Park murders were put on trial; on 14 July, Joseph Brady, who had been convicted of actual perpetration of the murder of Mr. Burke, was executed, as were others subsequently. The leading witness, who revealed all the secrets of his fellow conspirators, was James Carey of Dublin. He was shot dead near Natal, on 29 July, by an Irishman, O'Donnell, who was subsequently tried, and executed for his crime.

Invocation of Saints. See SAINTS.

In'vence, a list or bill of goods; a detailed statement of merchandise in stock, or to be shipped. Very frequently an invoice accompanies a shipment of goods along with the bill of lading from the consignor to the consignee.

IO—IODINE AND IODIDES IN MEDICINE

An invoice is a memorandum and is not a document of title nor a contract of sale, and has no value in law other than memoranda.

Io, iō, in Greek mythology, a daughter of Inachus; according to others of Iasus or Peiren. Zeus (Jupiter) fell in love with her. Hera (Juno) perceived the infidelity of her husband, and resolved to be revenged on both. Zeus, to protect Io from the jealousy of Hera, changed her into a beautiful white heifer. Hera was not deceived, and set a gad-fly to torment her, and persecuted her without a moment's rest through the world. The wanderings of Io in this condition were a favorite subject with the poets of ancient Greece. Also, in astronomy (1) the first satellite of Jupiter, discovered by Galileo in 1610. (2) The name of the 85th asteroid, discovered by Peters at Clinton, N. Y., 19 Sept. 1865.

Iodine, iō-din or -din, a non-metallic element, analogous in its general properties to chlorine and bromine. It was discovered by Courtois in 1811, in the mother-liquor of kelp that had been used for the production of sodium carbonate; occurring there in combination with sodium and magnesium. It is still obtained from the ashes of certain seaweeds, but the principal supply is now obtained from "caliche," a crude nitrate of sodium that occurs in immense quantities in northern Chile. In the preparation of the commercially pure nitrate of soda from caliche, the mother liquors, after the removal of the nitrate by crystallization, are found to contain large quantities of iodine, chiefly in the form of iodate of sodium, NaIO_3 ; and it is from this substance that the iodine of commerce is now chiefly prepared. The richest caliche contains about 3.5 pounds of iodine per ton.

In its ordinary form, iodine is a solid substance, melting at 237° F., and boiling at about 380° F. In a vacuum, iodine sublimes without melting. Solid iodine is soft, and dark gray in color, with a metallic lustre. The vapor is violet in color, from which circumstance the element takes its name (Greek, "like a violet"). Chemically, iodine has the symbol I, and an atomic weight of 126.85 for O = 16, or 125.9 for H = 1. Solid iodine has a specific gravity of about 4.95 at ordinary temperatures, and a specific heat of about 0.05412. Its volume increases, on account of thermal expansion, by about 0.00013 of its own value for a rise of temperature of 1° F. At temperatures not far above its boiling point, the vapor of iodine has a specific heat (at constant pressure) of 0.03369; and in this same region of temperature the ratio of its specific heat at constant pressure to the specific heat at constant volume is about 1.294. Iodine shows an important change in its vapor density at high temperatures. Thus, below about $1,200^{\circ}$ F. the vapor has a density about 126 times as great as that of hydrogen under the same conditions of temperature and pressure; but as the temperature rises the density of the vapor, relatively to hydrogen, falls off, until it is only about 68 at $2,700^{\circ}$ F. It is believed that this change in density indicates that the molecules of iodine vapor split in two as the temperature rises; a molecule, just above the boiling point, containing two atoms, while at the higher temperature the molecules are monatomic. Iodine is freely soluble in alcohol,

ether, carbon disulphid, chloroform, and glycerin. It is only slightly soluble in pure water, but dissolves readily in aqueous solutions of the iodides. It is also soluble in benzene, acetic acid, and numerous other organic fluids. Iodine is a non-conductor of electricity.

With hydrogen, iodine forms the important compound HI, known as hydriodic acid. (See HYDRIODIC ACID.) With the metals it forms binary compounds called "iodides," which may also be regarded as salts of hydriodic acid. Of these the most important is potassium iodide, KI, which is largely used in medicine. It is prepared by dissolving iodine in a solution of caustic potash, evaporating to dryness, and igniting. This salt is very soluble, and crystallizes in cubes. The iodides of ammonium, sodium, strontium, and zinc are also used to a more limited extent. Iodoform, a yellow crystalline powder with a peculiar characteristic odor when warmed, is also much used as a dressing in surgery. It has the formula CHI_3 , and is analogous in its chemical structure and deportment to chloroform. Iodoform may be prepared by dissolving iodine in an alcoholic solution of caustic potash, the iodoform that is produced separating out as a precipitate. It is also prepared in Germany, to a certain extent, by the electrolysis of a similar solution. (See LOB, 'Electrolysis and Electrosynthesis of Organic Compounds.') Iodine and its compounds are used to some extent in photography, and to a larger extent in synthetic chemistry, for the preparation of the coal-tar colors (q.v.), and other organic substances.

Iodine forms two important oxy-acids, known respectively as iodic acid, HIO_3 , and periodic acid, $\text{HIO}_4 + 2\text{H}_2\text{O}$. These are analogous, in their chemical deportment, to chloric and perchloric acids.

Free iodine combines with starch to form a remarkable deep blue compound, whose production is a well-known test for the presence, in a given substance, of either starch or free iodine. To detect the presence of iodine in a solution, a few drops of thin, clear starch paste are added to the solution to be tested (which should be cold), and hydrochloric acid is added until the reaction is acid. A couple of drops of a concentrated solution of potassium nitrite are then added, when the dark blue color of iodide of starch will instantly be produced, if iodine is present. This test may readily be modified so as to serve for the detection of starch. The reaction is not given by dextrin, nor by other isomers of starch.

Iodine and Iodides in Medicine. Iodine and the iodides have been used in medicine since the Chinese are supposed to have introduced them, 2000 B.C. or earlier. The exact method of action of the iodides is not clear, but it would seem that iodine, being a normal constituent of the human body, is a very essential element in normal metabolism. It is found in comparatively large quantities in the thyroid gland, which is known to exercise a very important action in the general body-metabolism, and it is probably by means of the stimulation of the general metabolism of the body that the iodides manifest their beneficial action. The iodides are freely absorbed from watery solutions by mucous membranes throughout the body, particularly in the stomach and intes-

IOLA — IONIAN ISLANDS

tine. They are taken up into the blood, pass through the tissues, stimulating the lymph-flow, and are excreted in the urine in the form of salts. Iodine itself possesses a local irritant action. It is soon converted into the iodides when taken internally, and causes similar internal changes.

When the iodides are taken in large doses, or even in small doses for a long time, a form of chronic poisoning known as iodism results. In this the chief symptoms, found in the air-passages, consist of a catarrh, especially of the nose, with profuse watery secretion, sneezing, and sometimes bronchitis. There is usually swelling and irritation of the throat and tonsils, and salivation. Nausea and gastric discomforts are common, and skin-eruptions are frequent. There is usually loss of weight, and if the iodide has been taken for a very long period a condition of cachexia, characterized by a great loss of flesh, weakness, depression, and restlessness, may result. The chief use of the iodides in medicine is in the treatment of syphilis, on which it has a specific effect. It is also very useful in the various joint-pains of a chronic character, usually known as chronic rheumatism. Iodine is valuable in the treatment of those diseases known to result from thyroid insufficiency, notably in myxoedema (q.v.), and in cretinism, its allied form in children. For stimulation of the respiratory and nasal passages, as in chronic bronchitis, asthma, and dry nasal catarrh, the iodides are of great value.

Iola, iō'lā, Kan.—The city of Iola, Allen County, Kan., is located on the left bank of the Neosho River, about 40 miles west of the Missouri line, and about 100 miles south of Kansas City. The town is reached by the Atchison, Topeka & Santa Fé, the Missouri, Kansas & Texas, and the Missouri Pacific railroads.

History.—It was laid out by the Iola Town Company in 1859. A post-office was located there the same year and a small village soon grew up. During the war the town made but little progress. In 1865 it became the county-seat of the county, and grew steadily, although very slowly until 1895, when its population was 1,565. In 1896 natural gas was discovered on the town site, and as soon as it was shown that a large gas field existed in and near the town it began to grow rapidly, the population in 1904 exceeding 11,000. This rapid growth followed the location in and near Iola of nine large zinc smelters, a number of brick factories, two Portland cement plants and other manufacturing enterprises attracted to the place by the cheap fuel which the large field of natural gas supplied.

Churches, etc.—The leading church denominations are the Presbyterian, Methodist Episcopal, Christian, Baptist, Episcopal, Reformed, and Catholic. The city is well supplied with schools, its high school being one of the best in the State. There are two daily papers, the 'Record' and the 'Register.'

Business, Population, etc.—The city is surrounded by a well-settled and prosperous agricultural community, but its chief business is derived from the manufacturing industries already named. The population is almost wholly American, the exceptions being a few Poles and Swedes employed in the manufacturing plants. An electric road connects Iola with a number of suburban towns, aggregating a population of about (1904) 5,000.

CHARLES F. SCOTT.

Vol. 9—8

Io'na, or Icolmkill, an island on the west coast of Scotland, one of the Inner Hebrides, in the county of Argyle. Iona is about 3 miles long by 1½ miles broad; area, 2,000 acres, of which 600 acres are under cultivation, the remainder being hill pasture, morass, and rock. The island derives its interest and celebrity wholly from its history and its ancient ruins, and especially from its connection with Saint Columba, who took up his residence here after the middle of the 6th century (565). The existing ruins are all, however, of a much more recent date. Forty-eight kings of Scotland, four kings of Ireland and eight kings of Norway are said to have been buried on Iona Island, among them being King Duncan, made famous by Shakespeare. About 1000 the Duke of Argyle conveyed the entire island to the Church of Scotland under certain conditions of preservation and restoration.

Ionia, iō'nī-a, that part of the seaboard of Asia Minor which was inhabited by Ionian Greeks, a beautiful and fertile country opposite the islands of Samos and Chios, which also belonged to it. According to tradition, the Greek colonists came over from Attica about 1050 B.C., and founded 12 towns, which, though mutually independent, formed a confederacy for common purposes. These included Phocæa, Ephesus, Miletus, etc., and latterly Smyrna. Commerce, navigation, and agriculture early rendered them wealthy and flourishing, but the country was made tributary by Croesus, king of Lydia, and later by Cyrus, king of Persia (557 B.C.). With an interval of independence they remained under Persia until this empire was overthrown by Alexander the Great, 334-1 B.C., when they became a part of the Macedonian empire. Ionia, at a later period, became part of the Roman province of Asia. It was afterward totally devastated by the Saracens, so that few vestiges of its ancient civilization remain.

Ionia, Mich., city and county-seat of Ionia County; on the Grand River, and the Detroit, G. H. & M., the Pere M., and the Grand T. R.R.'s; 34 miles east of Grand Rapids. It contains the State house of correction, the State asylum for the dangerous and criminal insane, large railroad repair shops, and manufactories of pottery, furniture, machinery, edged tools, and clothing. The industrial interests are greatly promoted by excellent power furnished by the river. The city has a public high school, library, several daily and weekly periodicals, and an assessed property valuation of about \$2,500,000. Under the revised charter of 1897, the government is administered by a mayor and city council elected annually. Ionia was settled in 1833 and incorporated in 1873. Pop. (1890) 4,482; (1900) 5,209.

Io'ian Islands, a number of islands belonging to the kingdom of Greece, in the Ionian Sea, off the coast of Albania and the western and southern shores of Greece, the most southern, Cerigo, and its dependent islets being off the southeastern extremity of the Morea. The principal islands, seven in number, are, reckoning from north to south, Kerkyra (Corfu), Paxos, Levkas (Santa Maura), Ithaki (Ithaca), Kephallenia (Cephalonia), Zakynthos (Zante), and Kythira (Cerigo). To each of these larger islands a number of smaller, scattered along their respective coasts, are attached, and in-

IONIAN PHILOSOPHY—IOWA

cluded in their several local jurisdictions. Area of the whole, 1,097 square miles. Pop. about 300,000. All these islands belong to the great calcareous formation of Greece. They are extremely mountainous, and do not contain enough arable land to produce the corn required by the population; and were it not for the vine, olive, and currant, all of which they produce, they could support but a small number of inhabitants. The climate is even more temperate than that of the neighboring mainland. Snow often falls in the winter, and lies on the mountains, but rarely on the plains. The staple exports are oil, currants, valonia, wine, soap, and salt. The few manufactures are chiefly textile and ornamental. The religion is that of the Eastern Greek Church, to which four fifths of the population belong. Each island has its own bishop, and at the head of the whole is an exarch or primate. The Ionian Islands, so called from lying in that part of the Mediterranean anciently known as the Mare Ionicum or Ionian Sea, often figure in the ancient history of Greece, but only singly, not collectively. In 1809–10 all the islands were overrun by the British troops except Corfu, which did not come into the hands of the British till it was assigned to them by the Peace of Paris in 1814, and the possession of the British was finally fixed and regulated by another treaty concluded at Paris in 1815. The seven islands were then formed into a republic, under the protectorate of Great Britain. In 1857 a wish was expressed by their representatives for reunion with Greece, and the islands, with the consent of the other European powers, were transferred to the kingdom of Greece in 1864.

Ionian Philosophy, the earliest school of Greek philosophy, a school which attempted to explain the phenomena of nature from the forces and attributes of matter itself. In order to do this the philosophers of this school followed two courses, some assuming a single original substance as the ground of all things, and explaining the development and formation of the phenomenal world by a process of condensation and rarefaction which they conceived as affecting the mode of existence of that substance; while others considered all things as formed by separation and combination out of a permanent and unalterable primitive form of matter. According to the view of the first class of Ionian philosophers, therefore, the original material principle was conceived as itself liable to change, and the changes which take place in it were held to give rise to the forms by which the world is known to us; while according to the view of the second class of Ionian philosophers the original material principle was looked upon as in its own nature and qualities unchangeable, and everything was explained by a change of external relations in space.

Ionian School, the school of philosophy which started from the Ionian city of Miletus. The leader of the school was Thales, who started from a disbelief in the current mythological fables of his day. Thales was born about 636 B.C. He was a man of political activity as well as of deep meditative habits. He was proficient in mathematical knowledge and founded the Ionian school which was principally concerned in an inquiry as to the constitution of the universe. He propounded the axiom that

the basis of all phenomena was water, and perhaps he was just as near the truth as Huxley when he declared that everything came out of what he called, by a question-begging term, protoplasm. The next philosopher of the Ionian school was Anaximenes 529 B.C. He also was a materialistic philosopher and like Liebig believed that the origin and substance of everything was air. Diogenes of Apollonia went farther than his predecessor and taught that the basis of phenomena was mind. The Ionian school found its highest development in Anaximander of Miletus 610 B.C., who taught what has been the profoundest discovery of all philosophy ancient or modern that the basis of being was *τὸ ἀτερπόν*, the Infinite.

Ionian Sea, that part of the Mediterranean communicating with the Gulf of Venice by the Strait of Otranto, and having Greece and part of European Turkey on the east; Sicily and the most southern part of Italy on the west. Its greatest breadth is between Cape Matapan in the Morea, and Cape Passaro in Sicily, which is about 400 miles.

Ion'ic Order. See ARCHITECTURE (*Greece*).

Ioniza'tion. See ELECTROLYSIS; ELECTRON; SOLUTION.

Ios, iōs, an island in the *Ægean Sea*, said to have been the birth-place of Homer. According to the ancients his mother was born here, and the poet's grave was likewise located here.

I O U, a written acknowledgment of debt, usually made in this form:—"To A. B. I O U Ten Dollars.—C. D. May 12, 1891." In Great Britain when the name of the creditor is stated such a document is evidence of a debt of the amount stated due to him by the person whose signature it bears. In the absence of the name of the creditor the document is *prima facie* evidence of such a debt being due to the holder of the document. It is not negotiable. The letters I O U are of course used instead of the words "I owe you," on account of the similarity of sound. The I O U is seldom used in the United States.

Iowa, iō-a ("the Hawkeye State"), a north-central State extending from the Mississippi River to the Missouri River, and occupying three and one sixth degrees of latitude. It is bounded on the north by Minnesota, on the east by Wisconsin and Illinois, on the south by Missouri, and on the west by Nebraska and South Dakota. Area, 56,025 square miles; 550 water; it is 310 miles east and west, and 210 north and south. Capital, Des Moines. Pop. (1900) 2,231,853. It is the sixteenth State in order of admission to the Union.

Topography.—Iowa is a part of the great central plain, and is chiefly undulating prairie, rising in gentle swells from the Mississippi River to a divide running diagonally, from a height of 1,604 feet in the northwest to a slight elevation in the southeast, with a parallel subdivide in the southwest. There are now no swamps and few natural forests. The only rough spots are the sharp bluffs where the rivers have cut their paths through the glacial drift; the only woods, those along the streams,—altogether about 7,000 square miles of woodland, with oak, elm, hickory, black walnut, maple, cottonwood, linden, ash, box-elder, pine,

IOWA

cedar, etc. The eastern watershed, two thirds of the whole State, is drained to the Mississippi by a series of streams, nearly all of which are parallel and have a southeastward course. The western part is drained to the Missouri by shorter and swifter rivers, flowing first southwest and then south as the Missouri turns eastward. The chief Mississippi affluents are the Upper Iowa, the Turkey, the Maquoketa, the Wapsipinicon, the Iowa, and the Cedar (the "main" stream, the Iowa,—375 miles, its "tributary," the Cedar, 400 miles, the two forming the second largest interior system of the State and joining not far from the mouth of the Iowa), the Skunk, and lastly the Des Moines with its numerous affluents, far the greatest and commercially the most important as well as the finest scenically, rising in Minnesota and running diagonally across the entire State in a course of 350 miles, with a basin of 14,500 square miles. The State is prolonged by a southeastern corner to include the entire channel of the Des Moines. The northern part of the State has a continuation of the many small, clear, pebbly lakes of Minnesota in glacier-scored pits; some of them—the Walled Lakes—surrounded each by a natural wall of loose stones. The largest are Spirit Lake and the two Okoboji lakes in Dickinson County, and Clear Lake in Cerro Gordo County, all popular summer resorts. West Okoboji, of great depth, lies between wooded hills, and is indented by several picturesque "points" or promontories.

Climate.—The winter climate is somewhat severe, owing to the influence of the great uninterrupted plains to the northwest; but like all this region, the severity is tempered by freedom from excessive moisture. The State is one of the healthiest in the Union, several of the streams in the northeast having rocky channels, and none having the miasmatic bottom-lands found farther south. The dry, pure air of its rolling prairies affords a valued sanatorium for consumptives. The extreme temperatures range from 110° above to 40° below zero; but the average range is from 95° above to 20° below. The average rainfall during the years from 1890 to 1903 inclusive was 31.4 inches—two thirds of it between April-October, and more than half during the critical crop months, May, June, July, and August.

Geology.—No less than five separate sheets of drift cover the State, giving a remarkable variety of productive soil, as well as many different clays for industrial purposes. The watershed shows the inclination to the underlying paleozoic rocks, in lines from northwest to southeast. The oldest formation is Sioux quartzite in the northwestern corner. Cretaceous deposits overlie the older formations through the northwest part generally; along the eastern side from north and south are Cambrian, Silurian, Devonian, and Carboniferous in succession. The most valuable mineral beds are the vast fields of bituminous coal, covering more than one third of the entire area of the State, and turning out in the year ending 30 June 1903, 6,185,734 tons, valued at \$8,016,274; employing 13,102 persons, of whom 9,169 were miners. It is the leading coal State west of the Mississippi except Colorado, and a great factor in all the northwestern industries. Its limestone, the finest grade of building stone, near Marshalltown, Anamosa and other points, is quarried to

the extent of about \$800,000 a year. Its gypsum from the rocky hills in the vicinity of Fort Dodge is the basis of a fast increasing manufacture of stucco, hard-wall plaster, and paint, also clays for pottery, fire and building brick, tile, and terra-cotta. Iowa ranks eighth in the value of its clay products. Considerable mineral water is also exported, that from the Colfax springs being in the lead.

Agriculture.—Iowa is unsurpassed in the quality and extent of cultivated land. It presents mainly a friable black loam on the top, from one to five feet deep; is easily worked, is in the main free from stumps and stones, and requires little or no commercial fertilizers. It has three main varieties, the principal being the alluvial mud of the river bottoms, the glacial drift of the prairies, covering most of the State, a sand and clay loam, and the loess, a rich yellow deposit containing much carbonate of lime, found at great depth on the Missouri slope and along the streams in the central and eastern portions. There is now almost no waste land in the State. In 1900 it presented the unparalleled record of 86.5 per cent improved farm land. A large part of the remaining 13.5 per cent yields income as timber and pasture land. With this fertility and a steady and sufficient rainfall, the State has for many years been first in the Union in value of products derived exclusively from the soil. The total value of its farm products in 1900 was \$365,411,528, of which over a hundred million was fed to its own live stock. Its great crop is corn; it varies, in bushels, from 129,104,930 in 1894 to 383,453,100 in 1900, with an average value of \$100,000,000 to \$150,000,000. A fourth of its surface is covered with cornfields. Its second crop is oats (of which it was second in the United States), with a total in 1900 of 168,364,170 bushels; third, barley, 18,059,060; wheat, 22,769,440; rye, 1,170,970; and buckwheat, 151,120. Its cereals altogether occupy nearly half of its area. It also raises considerable flaxseed. Its hay product is surpassed only by New York; in 1902 it was 5,211,232 tons, most of it used for feeding its own stock. The vegetable crops are also of great importance; in potatoes it was second in 1900, producing 2,662,660 bushels, also 224,622 bushels sweet potatoes, altogether realizing \$3,870,746; other vegetables, \$3,332,039. It has a considerable fruit crop, especially of apples; in 1900 the value of orchard products was \$1,849,767, besides \$878,446 of small fruits and berries. The average of Iowa's chief products during the 13 years, 1890-1902, in bushels, is: Corn, 201,200,750; wheat, 16,130,339; oats, 117,118,483; rye, 1,907,482; barley, 12,503,051; flax, 2,182,950; potatoes, 12,198,347; hay, tons, 5,517,884. Iowa leads all the other States in the value of the implements on its farms, namely, \$57,960,660.

Stock-Raising.—Iowa stands near the top in the value of live stock; \$278,830,096 in 1900; and it is significant that while one State, Texas, surpassed it in number of neat cattle,—9,428,196 to 5,367,630—the difference in values was only as \$163,228,904 to \$142,518,902; the average Iowa animal being worth \$26.55 against the Texan's \$17.31. In dairy cows New York alone takes precedence, and the value of dairy products in 1900 was \$18,819,000. That of poultry and eggs was \$19,508,000. Great care is taken to have the best breeds of stock, and

IOWA

this alone accounts for the difference in value of the Iowa and the Texas cattle. The richness of the milk is due largely to the breed. In the number of horses (1,268,016) and swine (9,723,791) Iowa led all the other States in 1900; and from 1850 to the last census there has been a steady increase in the number of swine, cattle, and horses.

Manufactures.—The State's fast-growing population and prosperity and its abundant and almost inexhaustible supply of bituminous coal have, together, within the last decade given a rapid impetus to manufacturing. Small factories have enlarged and many new factories have sprung up. Not a few of these are assuming large proportions. In 1900 Iowa manufactured 7,800 cultivators, 5,000 equalizers, 7,560 harrows, 34,560 hoes, 13,638 plows, 2,021 seeders, 100 drills, 3,720 harvesters, 3,775 hay-carriers, 10,980 dozen hay-forks, 5,800 horse hay-rakes, 79,296 scythes, 58,003 separators, etc., representing a total value of \$1,343,455—a gain of over \$400,000 in a single year. In the same year Iowa's product of metal-working machines was valued at \$273,501. There is but one manufactory of typewriters in Iowa (Des Moines), but it is fast becoming one of the foremost in the country, exporting largely to Great Britain, France, and the colonies. The output of carriages and wagons in 1900 was \$4,087,400; product of paints was \$336,867; chemical industries paid \$70,022 in wages. A curious industry has sprung up in and about Muscatine—the manufacture of pearl buttons from mussel shells found in the beds of streams. Almost unknown, it has grown to huge proportions, and now that the manufacturers have united in the protection of the sources of supply, the future of this industry is assured. The value of its products in 1900 was \$866,538, more than one fourth of which went for wages. The industry is now chiefly confined to the cutting of blanks for the eastern market. Iowa has 702 flouring and grist mills, two with a capacity of 100,000 barrels annually. The output of its mills in bushels is: wheat, 12,521,953; corn, 6,352,045; rye, 458,763; buckwheat, 277,593; barley, 538,740; other grain, 5,859,842. Cedar Rapids, Fort Dodge, and Muscatine have extensive oatmeal mills; the one at Cedar Rapids is said to be the largest in the world. The grand total of food products in 1900 was \$142,000,000. The slaughtering and meat-packing industry represented in 1900 a total product amounting to \$25,695,044. Cheese, butter and condensed-milk factory product in 1900 was \$15,846,077—an increase of nearly 50 per cent in 10 years. The fruit and vegetable canning product in 1900 was \$1,359,958—a gain of over \$800,000 in 10 years. Iowa ranks third in the canning of corn. The starch product in 1900 was \$806,831—a gain of over \$500,000 in 10 years; product of boots and shoes in 1900 was \$786,141, a gain of over \$200,000 in 10 years; product of gloves and mittens in 1900 was \$142,600; product of planing mills in 1900 was \$8,684,566. A fact not generally understood is that there is more timber in Iowa to-day than at any other time in its history. The clay products, which were \$175,165 in 1890, had increased in 10 years to \$2,224,920; to this should be added brick and tile products, which in 1900 aggregated \$1,979,322; also pottery, terra-cotta and fire-clay products, \$192,702. The paper product in 1900 was \$243,776. Dubuque has the

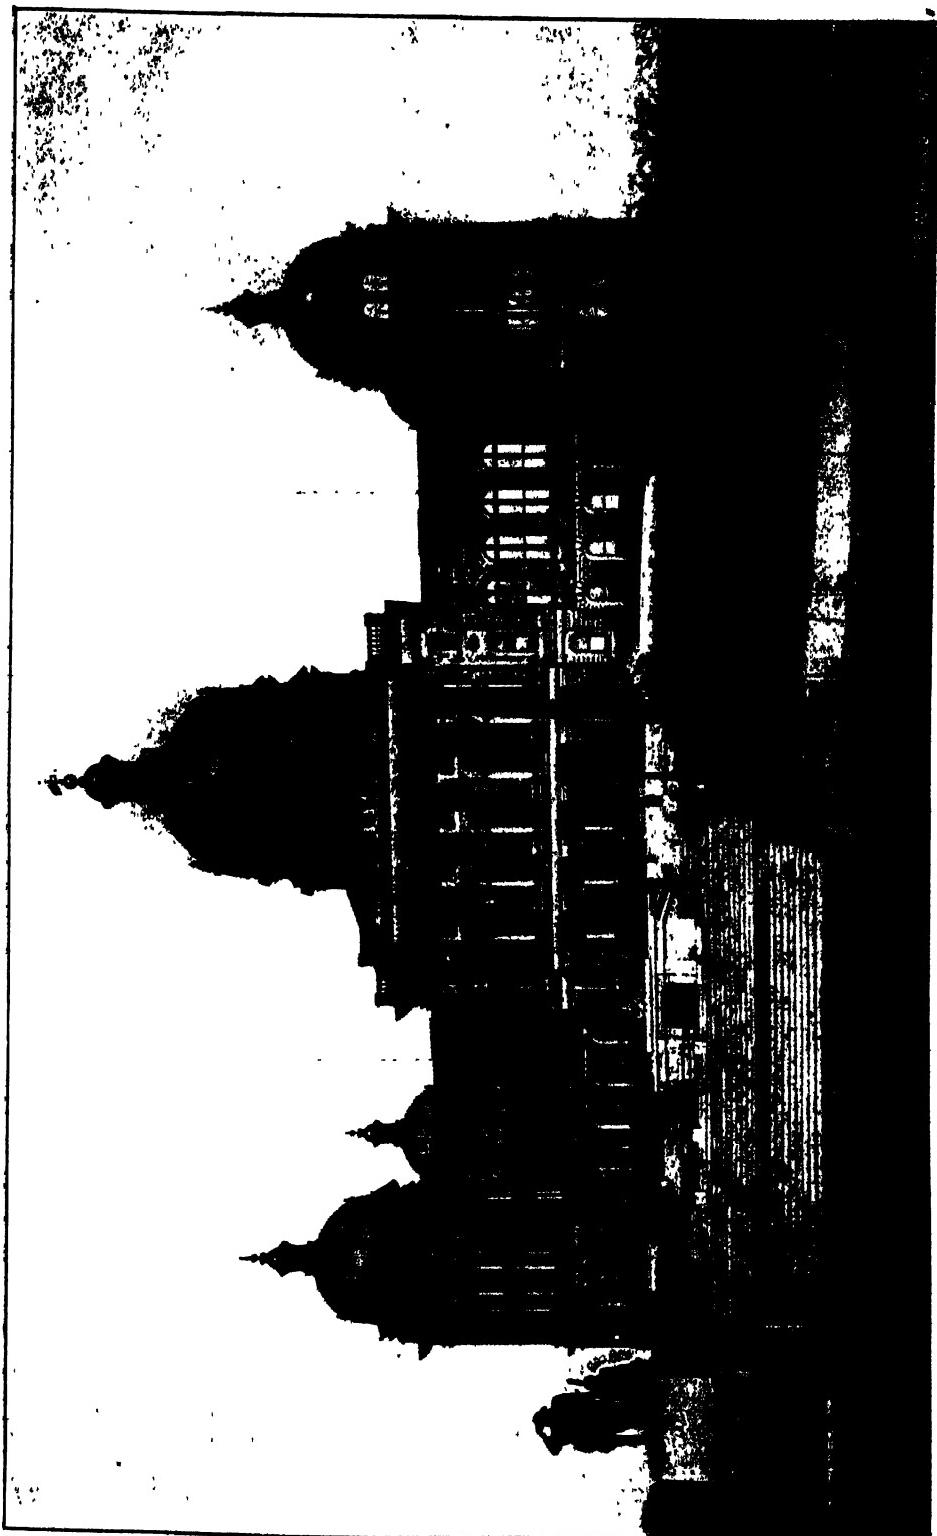

only ship-building plant in the interior. Among the larger cities Des Moines leads in brick-making (over 25,000,000 annually), proprietary medicines, book and job printing and binding, typewriters and hosiery; Sioux City, Ottumwa, Cedar Rapids, and Des Moines in meat-packing; Davenport, Dubuque, Burlington, Des Moines, and Ottumwa in foundries and machine works; Dubuque, Council Bluffs, and Grinnell in carriages; Burlington, Davenport, Des Moines, Dubuque, Ottumwa, Keokuk, and Oskaloosa in cigars; Sioux City, Des Moines, Cedar Rapids, Fort Dodge, Mason City, in flour and other food products; Des Moines, Ottumwa, Grinnell, Newton and Fort Madison in farm and other machinery; the principal river cities in malt products. The total value of manufactured products in 1900 was \$164,617,877—an increase of over 31 per cent in 10 years; the capital represented in 14,819 factories was \$102,733,103—an increase of over 32 per cent; the wages paid the 58,553 employes was \$23,931,680—an increase of over 17 per cent. These figures, showing enormous growth in the last decade, are a surprise to those who regard Iowa as distinctively an agricultural State.

Transportation and Commerce.—Several of the interior rivers are navigable for small boats, the Des Moines for 100 miles, the Missouri for fair-sized steamers its whole length, and the Mississippi for large ones. But the first named are not used to any extent; they have been superseded by railroads; the shifting channel, sandbars and snags of the Missouri make its navigation dangerous and slow. Only the Mississippi remains in practical use. The State, lying in the main path of transcontinental commerce, and originating much well-distributed local traffic, is a vast network of railroads, seven of the great trunk lines crossing it. Every one of the 99 counties has at least one railroad. The farthest distance between railroads at any point in the State is 13.79 miles. In 1903 it had 9,855 miles of road, exclusive of electric lines.

Banking and Insurance.—Iowa has the greatest number of banking institutions of any State in the United States. In August 1903, it had 1,482, divided into 258 national banks, 245 State banks, 350 savings banks, and 561 private banks. The State banks had capital of \$10,445,800; deposits, \$45,268,974.73; surplus, \$1,718,832.41. The savings banks had capital \$11,565,500; deposits, \$87,620,377.34; surplus, \$2,173,462.88. Total capital of all banks in the State, \$53,435,020; total deposits, \$264,803,000. Iowa is rapidly gaining prominence in the insurance world. In life insurance it promises soon to become a formidable competitor with the Eastern States. In 1902 there were 42 life insurance companies having headquarters in the State, and of this number 24 were located in Des Moines, "the Hartford of the West." Of the 42, 10 were "old line" life companies, carrying insurance to the amount of \$36,972,257; 8 were assessment companies, carrying \$209,955,500; 16 were fraternal benefit associations, carrying \$168,418,000. Total of insurance carried by Iowa companies, \$415,345,757.

Education.—Iowa stands second in the literacy of its population; 99.63 per cent of those from 10 to 14 years were, in 1900, able to read and write, although there was no compulsory attendance law prior to 1902. In 1902 it ex-

IOWA.

STATE CAPITOL AT DES MOINES.

IOWA

pended \$9,556,890 on its schools, there being 18,513 schoolrooms with 22,708 teachers holding certificates. The enrollment of children in the public schools in that year reached 560,173. There has been a liberal increase in the wages of teachers during the school year of 1902 and 1903. About one third of the schools are located in towns and cities and two thirds in the country. Relatively few of the teachers have had normal training. One State normal school and several private normal schools were in operation in 1900. In 1902 the State normal school had 28 professors and 28 other teachers, with 2,065 students. Under a law passed in 1902, 16 private schools have become accredited for the training of teachers under State supervision. For higher education there are about 200 public high schools and a number of private academies. The courses of study pursued are of high standard and generally uniform. The State University, the head of the public school system, is at Iowa City, the former capital, with law, medical, dental, and other colleges, which in 1902 had 48 professors, 111 other teachers, and 1,512 students. There is also a State College of Agriculture and the Mechanic Arts, located at Ames, which in 1902 had 32 professors, 43 other teachers, and 1,480 students. In 1902 a "Memorial University," at present a military academy, was opened at Mason City by the national order of the Sons of Veterans. Connected with certain of the public secondary schools there are 20 training classes for teachers. Among the private schools of the State there are 16 business colleges and 26 academies. Under the auspices of the Roman Catholic Church there are in the State 25 schools for higher education (academies and colleges), with an attendance of 4,040 pupils, 3 normal schools, 167 parish schools, with an attendance of 22,529 pupils. Iowa was one of the first States to pass a township school law. This law has enabled a number of towns to better their school facilities. In 1895 Buffalo Centre township, for example, was organized into a school township, and within four years all the district schools except two were closed and the pupils were transported to a central graded school. The law makes provision for the transportation, at public expense, of children living remote from the central school. The State report for 1901 shows that consolidation has been tried in 28 counties, transportation in 35, and both in 19. Good results were reported in 27 counties, doubtful in 5 counties. Bad roads are the chief obstacle in the doubtful counties, but a vigorous "Good Roads" movement is minimizing this obstacle. Ninety-five per cent of the county superintendents for 1901 favored the plan.

Libraries.—In 1893 there were 83 public libraries in Iowa, as follows: Supported by the State, 12 (volumes, 118,974); college and academic, 24 (volumes, 95,114); association and subscription, 16 (volumes, 81,234); free public, 15 (volumes, 68,809); miscellaneous, 7 (volumes, 46,176); public school, 5 (volumes, 7,850); total, 418,157 volumes. In 1903 the number of libraries had increased to 248, as follows: Supported by State, 22 (volumes, 236,953); college and academic, 36 (volumes, 179,261); association and subscription, 32 (volumes, 52,080); free public, 70 (volumes, 336,305); miscellaneous, 11 (volumes, 89,159);

public school, 77 (volumes, 75,982); total, 969,740 volumes.

Churches.—In the number of church societies in the State the denominations rank as follows: Methodist, Lutheran (three branches), Roman Catholic, Baptist, Christian (Disciples), Presbyterian, Congregationalist, United Brethren, Evangelical Association, Protestant Episcopal, Friends, Reformed, Adventist. There is one Roman Catholic archdiocese, with two dioceses. The non-polygamous Mormons or "Latter-day Saints," and the Amana Colony community of Christian Socialists, have a large and prosperous membership.

Charities and Penal Institutions.—The State charitable institutions are managed by a board of control appointed by the governor with the consent of the senate. There are four insane retreats: at Clarinda, Mt. Pleasant, Independence, and Cherokee; besides four private asylums; a school for the deaf at Council Bluffs; a school for the blind at Vinton; an institution for feeble-minded children at Glenwood; a soldiers' home at Marshalltown; and a home for soldiers' orphans at Davenport. There are State penitentiaries at Anamosa and Fort Madison, both have adopted the graded system; an industrial school for boys at Eldora, and one for girls at Mitchellville. L. S. Coffin has established a home for ex-convicts on his farm near Fort Dodge.

State Government.—The constitution was adopted in 1857. By law, the electors must vote once in 10 years on calling a convention to revise the constitution, which convention the legislature must call if so voted. All amendments must receive a majority vote of both houses at two successive legislatures, and then be passed by popular vote. The Senate has 50 four-year members, the House 100 two-year; legislative sessions are biennial. Bills must have a majority of all members elected to both houses—not merely present. A two-thirds vote overcomes the governor's veto. Executive officials are elected for two years—half in one year and half in the alternates, with the exception of the railway commissioners, who are elected for three; the railroad commission has power to regulate rates, etc. The judiciary consists of a supreme court, with a chief justice who is such by reason of priority of election, and five associate judges, one chosen every year; also 53 district judges in 20 districts, each serving four years. Women may vote only on school questions involving the expenditure of money. All incorporated towns of 2,000 people and over are ranked as cities; all platted but unincorporated towns are villages. In 1902 there was a militia of 2,474 officers and enlisted men. The number of representatives to Congress is 11. In politics the State has been Republican since the organization of the party, except in the years 1890-4, when the advocacy of prohibition drove it into retirement. The prohibitory amendment adopted in 1882 was pronounced unconstitutional by the supreme court of the State, and was succeeded by prohibitory laws which after several years' trial were in turn succeeded by a local option law, under which 54 of the 99 counties were reported in 1903 as wholly free from saloons.

Finances.—The State has no debt except one of \$10,936 to its own school fund, which debt by provision of the constitution is a permanent

IOWA CITY

one. It had a balance in the treasury 1 Jan., 1903, of \$926,916.65. Local taxation is limited to 1 per cent of valuation for current expenses, but this may be exceeded for waterworks, sewers, schools, etc. The State as a whole cannot incur a debt greater than \$250,000 except for war purposes, and cannot loan its credit to any person or association; counties and towns cannot run in debt to over 5 per cent of their actual valuation. The average income is about \$3,000,000 a year.

Population and Divisions.—Iowa ranks tenth among the States in population. The population was 43,112 in 1840; (1850), 192,214; (1860), 674,913; (1870), 1,194,020; (1880), 1,624,615; (1890), 1,911,896; (1900), 2,231,853. The original population was part of the great Free-State movement which peopled the central States except Indiana. Of the entire population (1900), 305,920 were foreign-born. Of these 123,162 were from Germany; 72,611 from Scandinavia, or nearly two thirds from the Teutonic nations; besides several thousands from German Austria and Switzerland. From England and English Canada were 35,195; French Canadians 14,168; Ireland 28,321; Holland 9,388. Colored, 12,603. There were 81,845 more males than females. There are no great centres of population. The capital, Des Moines, on the river of the name, is the largest, with 62,139. On the same river to the north is Fort Dodge, an old frontier fort and settlement (12,162), and below it Ottumwa (18,197) and Keokuk (14,641). The Mississippi River business is chiefly represented, from north to south, by Dubuque (36,297—the first settled site in the State), Clinton (22,698), Davenport (35,254), Muscatine (14,073), Burlington (23,201), Fort Madison (9,278), and Keokuk, the "Gate City," at the mouth of the Des Moines. Sioux City (33,111), in the extreme west near the mouth of the Big Sioux, and Council Bluffs (25,802), opposite Omaha, the old terminus of the Union Pacific, represent the Missouri River; Cedar Rapids (25,656) and Waterloo (12,580), the valley of the Cedar River; and Marshalltown (11,544), the valley of the Iowa River.

History.—The territory now included in Iowa was originally inhabited by the Ioway and Illinois tribes of Indians, which were driven out by the Sacs and Foxes. In 1761 the "Ioway" or Iowa tribes were on the east side of the Missouri River and near the headwaters of the Des Moines; but in 1805 they were occupying land on the south side of the Des Moines River. Later they left the vicinity of the Des Moines, some going to the reservation of the Foxes and Sacs (now Oklahoma), others to a reservation in Kansas. The missionary, Father Marquette, and Joliet, the fur trader, were the first white men known to have traveled in this section. In 1673 they visited the tribes of Indians along the Mississippi River, and first landed on Iowa soil near the mouth of the river now known by the name Iowa. In 1788 a party of 10 white men under Julien Dubuque established the first white settlement at the place now occupied by the city of Dubuque. They were attracted to this locality because of the lead deposits in the vicinity. They opened mines, but how successful they were may be conjectured from the fact that after the death of Dubuque, in 1810, his associates abandoned the settlement. All that portion of country drained

by the Mississippi was claimed by France because of the explorations made by Marquette and some of his companions, and because of settlements made by other Frenchmen. France's claim to this territory was ceded by treaty to Spain in 1763, but the country was returned to France in 1800-1. In 1803 all the territory now known as the "Louisiana Purchase" (q.v.) was bought of France by the United States government. The territory now the State of Iowa was part of the Territories of Louisiana in 1805; of Missouri in 1812; of Michigan in 1834; of Wisconsin in 1836. Iowa became an independent territory in 1838, and was admitted as a State in 1846. The Indian claims to lands within the boundaries of the State were purchased by the United States government before its admission as a State. The last purchase was made in 1843. Remnants of the Sacs and Foxes occupy a reservation, 419 acres, in Tama County, and still receive annuities from the government. In 1832 a settlement was made at Fort Madison, an abandoned government post, and soon after Burlington was founded, and in 1830 a settlement was again made at Dubuque. In 1837 the Indians attacked the settlers living near the Okoboji lakes and Spirit lake, in Dickinson County, and about 30 whites were killed and nearly all the houses burned. This action on the part of the Indians retarded for some years the growth of that section of the State. Iowa City was first selected for the Territorial capital (it became the State capital in 1846), but in 1857 the capital was changed to Des Moines. Iowa had in the Federal army during the Civil War 75,839 men, which was about one tenth of her population. Some of this number were in regiments belonging to other States. Consult: Aldrich, 'Annals of Iowa'; State Historical Society publications; Shambaugh, 'Documentary Material Relating to the History of Iowa'; Monette, 'History and Discovery of the Mississippi Valley'; Iowa Geological Survey publications; Shambaugh, 'History of the Constitutions of Iowa' and 'Messages and Proclamations of the Governors of Iowa'; Gue, 'History of Iowa.'

JOHNSON BRIGHAM,
Librarian, Iowa State Library.

Iowa City, Iowa, city and county-seat of Johnson County, on the Iowa River, and the Burlington, C. R. & N., and the Chicago, R. I. & P. R.R.'s; 54 miles west of Davenport. The city is pleasantly built on a succession of plateaus, rising one above another from the river banks, which are here high. The first plateau is laid out as a public promenade, and the third, which is about 30 feet higher than the first, is crowned by a handsome Doric edifice 120 feet long and 60 feet wide, of a beautifully marked stone quarried in the vicinity called "bird's-eye marble." This building was originally intended for the State capitol, but, on the removal of the seat of government to Des Moines, was appropriated to the State University. From 1839 to 1854, this was the seat of the Territorial and State governments. It is the seat of the State University of Iowa, the Iowa State Academy, the State Historical Society and Library, the Homœopathic, Allopathic, and Mercy hospitals. It is the farming trade centre for Johnson, Cedar, and Iowa counties, with an annual trade exceeding \$1,000,000; has excellent power provided by the Iowa River; and has

IOWA COLLEGE — IPHICRATES

manufactories of flour, iron, woolen goods, perfumery, gloves, jewelry, fencing, and linseed oil. The city has electric light and street railroad plants, waterworks on the Holly system, numerous churches, and an assessed property valuation of about \$6,500,000. Besides its manufacturing interests the city has an extensive stock-raising and meat-packing industry. Pop. (1890) 7,016; (1900) 7,987.

Iowa College, a coeducational institution founded in 1847 at Grinnell, Ia.; under the auspices of the Congregational Church. In 1901 it had 33 professors and instructors, 411 students, 27,000 volumes in the library; productive funds, \$470,000; grounds and buildings valued at \$150,000; and an income of \$49,000.

Iowa River, a considerable stream in the State of Iowa rising in Hancock County, near the Minnesota State line and flowing southeast into the Mississippi River, north of Burlington. It is 300 miles in length, and is navigable to Iowa City, 80 miles from its mouth.

Iowa State College of Agriculture and Mechanic Arts, a coeducational institution for technical education at Ames, Iowa. It received a grant of land from Congress under the law of 1862, and was first opened in 1868. Regular courses are offered in agriculture, mechanical engineering, civil engineering, electrical engineering, mining engineering, technology, science as related to industry, and general and domestic science; special shorter courses are given in the fall and winter in dairying, agriculture and mechanics, horticulture and mechanics, and domestic science. The State Agricultural Experiment Station is also allied with the college. The annual income in 1902, including the Federal appropriation, was \$120,000; there were 1,220 students in attendance, and 84 professors and instructors.

Iowa, State University of, an educational institution forming an integral part of the public school system of the State, situated at Iowa City. It was first opened in 1847, receiving control of lands given by the Federal government. (See COLLEGES, LAND GRANT.) The university is controlled by a board of regents of 2 *ex-officio* members and 11 elective members. Its work is organized in the following departments: the college of liberal arts (including the summer session), which offers courses leading to the degrees of A.B., B.S., and Ph.B.; the graduate college; the Iowa school of political and social science, with both undergraduate and graduate courses; the college of law; the college of medicine; the college of homeopathic medicine; and the college of dentistry. The library, which lost 25,000 volumes by fire in 1897, now contains nearly 65,000 volumes; the university issues the following publications: 'Natural History Bulletin'; 'The Transit,' an engineering journal; 'The Law Bulletin'; 'The Bulletin of the Homeopathic Medical College'; 'The University of Iowa Studies in Psychology'; 'The State University of Iowa Studies in Sociology, Economics, Politics and History.' The State appropriates over \$125,000 annually to the university, and the total income amounts to over \$300,000 annually. In 1902 the number of students was 1,512; the number of professors and instructors, 160.

Iowa Wesleyan University, a coeducational institution founded in 1844, at Mount Pleasant, Iowa; under the auspices of the Methodist Episcopal Church. In 1901 it had 20 professors and instructors, and 380 students. There are 5,000 volumes in the library. It has productive funds, \$75,000; grounds and buildings valued at \$150,000; benefactions, \$32,000; and an income of \$14,000.

Iowas, a tribe of American Indians of the Algonquin family. In 1800 the Iowas lived in Minnesota and soon after moved southward. They were called Palinchas, or "Dusty Noses," in their own tongue. Lewis and Clark, the explorers, designate them as the Ayanways, and the early French traders called them the Ajowes. In 1836 they moved to the Wolf River region west of the Mississippi, and in 1861 ceded 16,000 acres of land to the United States. The remnants of the tribe, some 1,000 in number, at present live on reservations in Oklahoma and Kansas. See also INDIANS, AMERICAN; IOWA.

Ip'ecac, or Ipecacuanha, a South American plant of the order *Rubiaceæ* variously called by botanists *Cephaelis ipecacuanha* and *Psychotria ipecacuanha*. The plant, which is found mainly in moist shady forests in Brazil, is a creeping herb or sub-shrub with mostly bare stems, only the extremities producing leaves. The small white blossoms, which are borne in heads with long stalks, are followed by dark purple berries. The rather fleshy more or less divided roots were in medicinal repute among the South American Indians, and gradually found their way into European medicine under the name "ipecacuanha." They have been considered emetic, nauseant, diaphoretic and expectorant, and in large doses are reputed poisonous. They appear in commerce in various grades (gray, brown and red), which are dependent mainly upon the season at which they are gathered, the way they are dried, the age of the plants, etc. The chief supplies are collected during January, February and March by the Indians. Owing to the slow growth of the plant and the low price the roots command, ipecac is not cultivated commercially; it has, however, been successfully grown in various parts of the world. The roots of several other plants are substituted for those of true ipecac, among the best known being those of *Tylophora asthmatica* and *Sarcostemma glaucum* (Venezuelan ipecac), both of the natural order *Asclepiadaceæ*. Other species of *Psychotria* and certain species of *Richardsonia* are similarly but unofficially employed.

Wild or American ipecac (*Gillenia stipulacea*) of the rose family, is a common plant in the southeastern United States and as far north as western New York. It is a perennial herb about three feet tall, bearing paniculate corymbs of white or pale rose colored flowers. It is hardy, of simplest culture and being graceful is frequently planted for ornament in flower borders where the soil is of good quality.

Iphicrates, i-fik'rə-tēz, Athenian commander: b. and d. in the 4th century B.C. Of humble origin, he raised himself to eminence by his courage and talents. In the war of Corinth (393-2 B.C.) he opposed with success Agesilaus, the warlike king of Sparta. He was sent to the Hellespont to act against Anaxibius, but in spite of his victory was unable to prevent the

IPHIGENIA — IRANIAN LANGUAGES

conclusion of the shameful Peace of Antalcidas (387 B.C.). In 369 B.C. he was appointed to the command of the troops sent by the Athenians to the assistance of Sparta, on the invasion of Epaminondas, but allowed the Theban general to retreat from the Peloponnesus. In the Social War (357-5) he was one of the commanders of the fleet fitted out by the Athenians for the recovery of Byzantium. Being accused of treachery by one of his colleagues and put on trial he was acquitted; but though he lived to a great age, did not again engage in active service. Iphicrates was the author of some improvements in Greek arms and accoutrements. He was accustomed always to fortify his camp in the field even in a friendly country; "Because," he said, "if, contrary to probability, I should be attacked, I may not be obliged to make the disgraceful excuse that I did not expect it."

Iphigenia, if-i-jē-nī'ā, in Greek legend, a daughter of Agamemnon and Clytemnestra (according to some an illegitimate daughter of Theseus and Helen), who was to have been sacrificed to Artemis (Diana) at the advice of the prophet Calchas, when the goddess, enraged with Agamemnon, detained the Greek fleet in Aulis by a calm. Under pretense that she was to be married to Achilles, Iphigenia was led to the altar. But in the moment when the priest was about to give the death-blow Iphigenia disappeared, and in her stead a beautiful hind was substituted, whose blood gushed out on the altar. Artemis had relented, and conveyed her in a cloud to Tauris, where she became the priestess of the goddess. Conformably with the law of the country, she was obliged to sacrifice every Greek that landed there. While serving as priestess her brother Orestes came to take away the image of Artemis, as he had been advised by an oracle to do, that he might get rid of the madness to which he had been subject since the murder of his mother. Iphigenia having recognized him as her brother, the two contrived a means of escape, and carried off with them the image. The story of Iphigenia was dramatized by Euripides (who composed two plays upon the subject—"Iphigenia in Aulis" and "Iphigenia in Tauris"), and Goethe, and it is also the subject of two operas by Gluck, "Iphigénie en Aulide" (1774); and "Iphigénie en Tauride" (1779).

Ipomœa, ip-ō-mē'ā, a genus of plants, including several hundred species, of the order *Convolvulaceæ*, consisting mostly of twining prostrate herbs, widely distributed in warm regions. The species of most importance is *I. Purga*, which yields the jalap of commerce. Some are cultivated for the beauty of their flowers, and are known to gardeners as convolvuli. *I. purpurea* is the best known garden species. See JALAP.

Ipsambul, ip-sām'boul. See ABU-SIMBEL.

Ips'wich, Mass., town in Essex County, on the Ipswich River near its mouth, and on the Boston & Maine railroad, 27 miles northeast of Boston, and 9 miles south of Newburyport. As Agawam, it was settled in 1633 by John Winthrop and 12 others. The name was changed to Ipswich (after Ipswich, England), in the following year, by resolution of the Massachusetts General Court. As early as 1634 it had a meeting-house, while in 1642 the first free school

in the town was established. Ipswich was among the foremost towns of Massachusetts in resisting the arbitrary taxation introduced under Gov. Andros in 1687, and a number of its citizens suffered punishment in consequence of this action, which foreshadowed the stand to be taken later, by this town and the colonies generally, against similar policies on the part of the British government. Among the distinguished persons who at some time lived at Ipswich were Anne Bradstreet, Nicholas Easton, William Hubbard, John Norton, and others. The town has various industries, among the articles manufactured being grist-mill products, hosiery and underwear, bricks, lumber and boxes, carriages, cabinet-work, soap, isinglass, heels, etc. The Manning High school, the Ipswich Historical Society, and the excellent public library give the town rank and influence in educational and literary affairs. Pop. (1900) 4,658.

Iquique, ē-kē'kā, Chile, a seaport in the province of Tarapacá, till quite recently merely a small fishing village, but now a town of about 34,000 inhabitants. It owes its prosperity to the export of nitrate of soda and borax, the former of which especially is found in great quantities in the pampa of Tamarugal. The annual export of nitrate amounts to about 350,000 tons, and that of borax to about 1,500 tons. Iodine is also exported. The pampa of Tamarugal still contains, it is estimated, about 60,000,000 tons of soda niter. In 1868, and again in 1877, the town was almost entirely destroyed by an earthquake. In 1879 it was bombarded and captured by Chile from Peru; and in 1891 it was much damaged by insurgents.

Iquitos, ē-kē'tōs, a native tribe in Peru, residing at Loreto, on the left bank of the Marañón, about 75 miles above the mouth of the Rio Napo. The settlement has an active trade, valued at \$2,000,000 annually; the imports are exchanged mostly for india rubber. In 1900 they numbered about 12,000.

Trade, i-rā'dē, a Turkish decree or command of the Sultan, directed to his grand vizier, whose duty it is to announce it to the public.

Iran, ē-rān', the name given by the ancient Persians to their native land, in opposition to Aniran (that is, Not Iran), the land of the barbarians, by which term were meant principally the Turco-Tartaric tribes bordering on the north. The Persian rulers of the dynasty of the Sassanidæ call themselves, in inscriptions on monuments and elsewhere, kings of Iran and Aniran. At the present day the name is used in contradistinction to Turan, the name applied to the more depressed regions of Asia inhabited by the Turco-Tartaric tribes, to designate the great table-land of Asia, which has a mean elevation of from 3,500 to 4,000 feet. The central portion of this table-land consists of an extensive salt-desert.

Iranian (i-rā'nī-an) **Languages**, a family of the Indo-European languages, closely allied to the Indian group, and called by some philologists Persian, from the best known member of the family. The two oldest known Iranian languages are the Old Persian and Zend. The former—that of the cuneiform inscriptions of the Achæmenian dynasty, and the language of the Persians proper—has only become known

JOHN IRELAND.

ARCHBISHOP OF ST. PAUL.

IRAPUATO — IRELAND

in its chief traits at a comparatively recent date through the deciphering of those inscriptions. The Zend is the language in which the Zend-avesta, the sacred writings of the Parsees, are composed. By the term Middle Iranian languages the Huzvaresh or Pehlevi and the Parsi principally are understood, which are preserved in the commentaries to the Zend-avesta. The latter approaches to the modern Persian. The dialect of the Pehlevi coins, as well as the inscriptions of the time of the Sassanian dynasty, also belong to this section. The most important of the New Iranian languages is the Persian, in which has been produced a very rich and celebrated literature, and which as a cultivated literary language is distinguished from the dialectic varieties of the different regions of Persia which European scholars are as yet only partially acquainted with. The Afghan, or Pashtu, and the dialects of the Kurds, form separate branches of the Iranian family. The isolated Ossetes of the Caucasus also speak an Iranian language. The Armenian is a branch of the same stock, and contains many peculiar elements.

Irapuato, ē-rä-poo-ä'tō, Mexico, district town in the province of Guanajuato, on the Mexican C. railroad, about 30 miles south of the city of Guanajuato, capital of the province. The climate of this region is mild and favorable to the growth of fruits, of which strawberries and other varieties are produced in abundance. Several ancient churches, convents, etc., give the town an interest for visitors. Pop. about 20,000.

Irawadi, ir-a-wä'di, or **Irrawaddy**, one of the great rivers of Southern Asia, traversing Burma in a southerly course. One branch of it rises near the eastern extremity of Assam, another branch rises in East Tibet, the two branches uniting about lat. 26°. It has generally a south course, being deflected west, and its total length has been estimated at 1,200 miles. There are three rocky defiles in which its channel is suddenly contracted, the lowest near Mandalay; but from that point downward to its delta it has generally a breadth of from 1 to 4 miles. About 140 miles from the Indian Ocean, which it enters by numerous mouths, the delta commences. The current of the Irawadi is commonly gentle—even in its upper part being no more than at the rate of two miles an hour; except during the inundations, when it flows so rapidly that no sailing vessels could navigate it but for the assistance of the southwest monsoon. It is navigable from the sea upward for steamers of five feet draft to the Chinese frontier, 900 miles from the sea. Like the Nile, the Irawadi is the main artery of the country through which it flows; the principal population of Burma is established along its banks.

Iredell, James, American jurist: b. Lewes, Sussex, England, 5 Oct. 1751; d. Edenton, N. C., 20 Oct. 1799. He was appointed comptroller of customs at Port Roanoke, now Edenton, where he arrived in 1768, retained this office several years, and meanwhile studied law. He was appointed by the attorney-general his deputy in 1774, and in 1777 was placed by the legislature on the bench of the supreme court, then just organized under the State constitution. In 1787 he was designated by the general assembly sole commissioner to collect and revise the acts of previous assemblies, which were to be considered in force in North Caro-

lina. This collection of the laws, now referred to as "Iredell's Revisal," was published in 1791. In February 1790 he became one of the justices of the Supreme Court of the United States, and held that office till his death. The 'Life and Correspondence' of Iredell was published in 1857.

Iredell, James, American lawyer, son of the preceding: b. Edenton, N. C., 2 Nov. 1788; d. Raleigh, N. C., 13 April 1853. He was graduated at Princeton in 1806, and was bred to the bar. He served for 10 years in the house of commons of his native State, and twice as speaker in a house of which the majority were politically opposed to him. In 1827 he was governor of North Carolina, and from 1828 to 1831 a member of the Senate of the United States. He afterward resumed the practice of his profession at Raleigh, where he was also for many years reporter of the decisions of the supreme court of North Carolina. In 1833 he was appointed by Gov. Swain one of three commissioners to collect and revise all the statutes in force in North Carolina. The result was the work known as the 'Revised Statutes.' He afterward published a 'Treatise on the Law of Executors and Administrators.'

Ireland, ir'länd, Alleyne, American author and lecturer: b. Manchester, England, 19 Jan. 1871. He was educated at the University of Berlin, traveled widely, lectured on tropical colonization at Cornell University in 1899, and in 1900 was appointed lecturer in politics at the University of Chicago, where his subjects were tropical colonization and Chinese foreign relations. In addition to numerous contributions to periodicals, he wrote: 'Georgetown, Demerara' (1897); 'Tropical Colonization' (1899); 'The Anglo-Boer Conflict' (1900); 'China and the Powers' (1901).

Ireland, John, American Roman Catholic prelate: b. Burnchurch, County Kilkenny, Ireland, 11 Sept. 1838. He was educated in the cathedral school at St. Paul, his parents having come to the United States in his childhood. He studied theology in France four years at Meximieux, and four at Var, and was ordained priest in 1861. During the Civil War he was chaplain to the 5th Minnesota regiment; he was afterward appointed rector of the cathedral at St. Paul, and secretary, afterward coadjutor bishop of St. Paul. He succeeded to the see as archbishop of St. Paul in 1888. He took an active part in founding the Roman Catholic University in Washington, organized the first total abstinence society in Minnesota and has been one of the foremost temperance advocates in the American branch of his church. In 1887 he was instrumental in promoting temperance revival in England and Ireland. He has published 'The Church and Modern Society'; etc.

Ireland, Mary E. Haines, American translator and author: b. Calvert, Cecil County, Md., 9 Jan. 1834. In addition to serials and numerous other contributions to the periodical press, she wrote 'What I Told Dorcas' (1895), and 'Grandma Elliot's Farmhouse' (1900); and she also translated from the German a lengthy series of minor works of fiction.

Ireland, William Henry, English literary forger: b. probably London 1777; d. there 17 April 1835. He imposed spurious Shakespearian

IRELAND

MSS. upon his father, Samuel Ireland, a bookseller and engineer, who was a Shakespeare enthusiast, and also upon other men of letters, and produced two "Shaksperian" plays, "Vortigern" and "Henry II," the former of which was purchased by Sheridan and acted at Drury Lane, but was a complete failure. The criticisms of Malone led to the exposure of the fraud, which was acknowledged by Ireland in 1796. He wrote various novels, poems, etc., besides his "Confessions" (1805), containing an account of his forgeries.

Ireland, the most westerly and smaller of the two principal islands of which the United Kingdom of Great Britain and Ireland is composed, extends from lat. $51^{\circ} 26'$ to $55^{\circ} 21'$ N.; its average width is about one fourth its length; area, 32,583 square miles. It is separated from England by Saint George's Channel and the Irish Sea, and from Scotland by a narrow passage, the North Channel. Ireland is on the continental shelf, or sub-marine plain, which borders the continental land mass of Europe, hence it is physically a part of Europe.

Topography.—The coast line is irregular; from Dundalk Bay to Wexford Harbor on the east there are less indentations than on any other part of the coast; Dublin Bay, an arm of the Irish Sea, is the only indentation of any size on this part of the island. Galway, Sligo and Donegal Bays are the largest on the western coast. The Atlantic currents, which beat against the western coast, have worn away the land in many places, thus causing fiords such as exist on the coasts of other countries subject to similar wave-action. Some of the many islands which fringe the coast have been formed by the washing away or the submergence of the land. The capes, promontories, and peninsulas have been formed largely by submergence. Some of the islands, all small, are Aran, Achill, Clare, and Rathlin. The chief ports are Cork, Dublin, Belfast, Waterford, and Londonderry. There are 14 harbors which will accommodate the largest ocean steamers.

The highlands are chiefly along the coast; the greater part of the interior is a plain. The mountains, more rounded hills than mountains, are short ranges with little or no connection except the several ranges in the southwest. Some of the mountains are Mourne, in County Down, the Wicklow Mountains, Knockmealdown and Galty in the south; Caha, Stack and other ranges in Kerry; Slieve Boughta in Galway, a number of short ranges in the counties of Mayo, Leitrim, Donegal, and Londonderry, and the Slieve Bloom between Queens and Kings counties. The majority of the peaks are less than 3,000 feet in height; Carrantuohill (Carrantual), in Kerry, near the Lakes of Killarney, is 3,404 feet, and Galty Mountains, in Limerick, are 3,015 feet. The plain in the interior is about 500 feet above sea-level.

Hydrography.—The rivers of Ireland, like those of England and Scotland, are small streams. The Shannon, the largest river in the British Isles, has its rise in the northeastern part of the province of Connaught, flows east, south, and west, forming quite a curve before entering the Atlantic Ocean, between the counties of Kerry and Clare. It passes through several lakes, the largest of which are Ree, Allen, and Derg. The estuary at the mouth is about 70

miles long; the whole length of the river is about 250 miles, 130 of which are navigable for large steamers. Its importance for transportation has been increased by the canals Royal and Grand, which connect it with Dublin. In the southwest, in County Kerry, is a short mountain stream called Roughly River, with a long, broad estuary called Kenmare River. The Liffey, which flows into the Irish Sea at Dublin, the Lee which flows into Cork Harbor, the Boyne with its tributary, the Blackwater, are all short streams which have been made famous in history and literature. The Foyle, Erne, Lagan, Moy, Slaney, and others reach the ocean through broad estuaries or bays. Lough Neagh in the northwest is the largest lake of the British Isles. A number of the lakes of Ireland occur along the river courses, but are really basins, and not merely expansions of the rivers. Lakes Corrib, Conn, Foyle, Belfast, Strangford, Carlingford, and others on the coast are estuaries or fiords, but the land-locked mouths entitle them to be called lakes, like Maracaibo in South America. The famous Lakes of Killarney are in County Kerry, in the southwestern part of the island. There is scarcely a place in Ireland that is more than 25 miles distance from water communication with the ocean.

Geology.—A limestone stratum belonging to the basal portion of the Carboniferous system underlies a large part of the interior plain. The upper Carboniferous rock has been destroyed by erosion except in a few places. Silurian rock underlies nearly all of the northern part, but the Cretaceous, Triassic, and Permian formations exist and appear at the surface in several places. Some of the cliffs of the north are of basaltic formation. The Giant's Causeway (q.v.) on the north coast of Antrim is basaltic. Its 40,000 or more, perfectly formed polygonal columns constitute remarkable specimens of this formation. Crystalline rocks form the axis of the mountains of the province of Connaught, and the highlands of Leinster. Old red sandstone and carboniferous limestone are found in the southwestern counties. Marble exists in large quantities in the county of Kilkenny and in parts of the adjacent counties coal of an anthracite variety is found, but not in large quantities; iron-ore exists in nearly every county. Copper of an excellent quality is in the western mountains, also gold and silver in small quantities.

Soil.—The erosion of the limestone rock which has been going on for ages has contributed largely to the fertility of the soil of Ireland. The igneous rocks, the red marls, and other mineral formations, have added to the richness of the soil, and all has been distributed, by the gradual removal of the ice-covering, over a large area of the plain. After deducting the area, about one fifth of the whole, which is covered by bog, mountain, and moorland, there is left a vast extent of arable surface covered with a deep friable loam of remarkable richness. In addition to the decomposed trap and the calcareous matter derived from the limestone, there is a large amount of vegetable mold which forms one of the most important ingredients of the soil. The bogs, useless for tillage, furnish peat for fuel. The Bog of Allen is the largest one in Ireland.

Climate.—The warm moist winds from the Atlantic blowing over Ireland affect its climate more than any other cause except its latitude.

IRELAND

The mean temperature is from 20° to 30° F. higher than other places in the same latitude on the eastern coast of America or the interior of Europe, and a few degrees higher than places in the same latitude on the west coast of America. The summer temperature is modified by the surrounding waters, being lower by a few degrees than inland places of the same latitude. The moisture brought by the winds from the ocean causes a heavy annual rainfall, and much fog, mist, and general dampness. The low mountains serve to some extent as condensing agents, so that the greatest rainfall is near the coast. The average rainfall on the west and south coasts was, in 1879, 43.56 inches; in 1896, 36.36. The averages for the interior were in 1879, 34.39 inches; in 1896, 34.07 inches.

Vegetation.—The climate and soil are very favorable for vegetation. Its mild temperature and humid atmosphere enable several delicate plants, which usually in the same latitude can be cultivated only in sheltered gardens, to flourish here with vigor in the open air; and frequently forest trees continue to retain their foliage after similar trees have lost their leaves in the warmest parts of England. The conditions would naturally indicate forests, and it seems that in early times, large tracts of magnificent timber were spread over its surface; but the grossest waste and mismanagement have prevailed, trees have almost disappeared except from the parks of the wealthy land-owners, or the "gentry"; and what ought to be among the best is about the worst wooded country in the middle latitudes of Europe. More attention is now being given to the subject of forestry; in 1901 there were 309,741 acres in Ireland under forest, a portion of which was a new growth. During the year, 1,740 acres were planted with trees, mostly fir, spruce, and larch. Grass grows luxuriantly in nearly all parts of the island.

Animals.—The fauna of Ireland consists now of birds and small rodents. Animals once found here and mentioned in the ancient literature, as the deer, bear, wildcat, wolf, beaver, cattle peculiar to the island, and certain birds (including the garefowl), have all disappeared. There are no snakes nor toads in Ireland. Fish are plentiful in the streams and on the coasts.

Fisheries.—The salmon fisheries are very valuable, and are increasing in value every year. With an increased supply of fish, high prices are maintained owing to the improved means of communication from remote districts with the best markets. In spite of this, however, these fisheries are not cultivated to anything like so high a degree as they might be. Still, the number of men engaged in the salmon fisheries in Ireland is over 13,000, the estimated value of the salmon exported being from \$700,000 to \$950,000 annually. The principal sea fisheries of Ireland are those of herring and mackerel. The herring fisheries in the Irish waters are prosecuted chiefly on the east coast by Irish boats from Howth, Arklow, and other places on the Irish coast, and by a fleet of vessels from Cornwall, Scotland, and the Isle of Man. The number of boats engaged in this branch of the sea fishery is much smaller than in Scotland, from which considerable quantities of cured herrings are imported. The total number of vessels engaged in the sea fisheries is now about 6,525, the number of men and boys employed being about 26,200. The native fishermen, it is said, are now success-

fully competing with their rivals, yet the sea fisheries of Ireland on the whole have much declined, as shown by the decrease from 55,630 hands and 13,483 boats employed in 1860, to the figures just given.

Agriculture and Stock-raising.—The chief occupation is agriculture. The richness of the soil, its lightness that makes tillage easy, the large percentage of arable land, the amount of rainfall, the mildness of the climate, all combine to make Ireland an agricultural country. Despite the great extent of moorland-wastes and the large amount of bog-land, few countries raise, in proportion to the area, such a large amount of food products year after year. But with natural advantages above the average, agriculture as a system has not progressed as in many other countries. The wholesale confiscation of estates by the English gave the absentee landlord a large portion of the farm land of Ireland. The new owner usually cared only for his rent and gave little heed to improving the land, and showed no regard for the welfare of the man who tilled the soil. The holders and laborers received no encouragement to improve methods or make progress; on the contrary, they were handicapped in many ways, especially in the 18th century, when the English markets were closed to their products, and Ireland was excluded in a large measure from the commercial advantages given to the British possessions in other parts of the world. The holdings, or farms, originally too small to be occupied by farmers of capital and enterprise, were in many cases subdivided until they were reduced to the smallest patches, on the produce of which a family could barely subsist. One result of this poor policy was that the holders were obliged to raise as much as possible each year, for immediate use, without regard to the ultimate effect of this mode of farming upon the land. Competent authorities say that this over-cropping has had a most deleterious effect upon the land. Yet the soil must have been restored to some extent, by rotation of crops or by the use of fertilizers, for the average produce of the soil per acre, in 1902, was found to have increased over the years 1850 and 1860. In some cases the holdings were enlarged during the last years of the 19th century. Statistics show that a change in the kind of crops has been gradually taking place; a decrease in the acreage under cereals and green crops and an increase in the area under meadow and clover. The following table shows the distribution of the cultivated area, given in acres, the first years of the present century:

YEAR	Green		Clover	
	Cereal, crops	Flax and hay	Flax and hay	Pasture
1900...1,347,189	1,098,377	47,451	1,218,717	11,510,379
1901...1,317,574	1,079,443	55,442	1,233,770	11,522,060
1902...1,306,398	1,070,449	49,746	1,228,498	11,575,592

The number of acres of farm land not under crops, but "resting," was, in 1900, 12,589; in 1901, 10,886; and in 1902, 9,558.

Between 1851 and 1881 the farms of 1 to 15 acres decreased in number by 66,363. The total number of holdings in 1891 was 486,865, or 12,244 less than in 1881. Of these 18,243 (1,304 more than in 1881) did not exceed 1 acre, 55,584 (decrease of 6,197) were from 1 to 5 acres, 139,195 (8,628 decrease) from 5 to 15 acres, 120,472 (2,045 decrease) from 15 to 30 acres, and 139,401 (3,202 increase) above 30 acres. Each province

IRELAND

shows a decrease in the total number of holdings, but in Munster the number is very small. Between 1841 and 1890 there was a total decrease in holdings "above 1 acre" of 25 per cent.

The Land Act of 1870 greatly improved the conditions of tenure in Ireland. The chief aims of the act were to provide compensation to tenants for arbitrary eviction, and especially for improvements effected by them on their holdings in case of their being disturbed in their possession by the landlords, and to afford facilities to tenants for the purchase of their holdings. The act legalized what is called the Ulster tenant-right custom in all the districts in which it prevailed, and decreed the amount of compensation to be awarded in absence of such custom. In 1881 it was supplemented by a more thorough and comprehensive measure. The benefits conferred on Irish tenants by this act were briefly summarized under the terms "fair rent," "fixity of tenure," and "free sale." By the first of these every tenant who objected to his rent, or the rent the landlord wished to exact, was entitled to have a "fair rent" fixed for him by a court. The rent was to remain unaltered for 15 years, at the end of which period it might be readjusted, and raised or lowered. By the principle of "fixity of tenure" the law recognized that the tenant had a certain right in his holding in virtue of which he was not to be arbitrarily removed from it without compensation, and which enabled him on leaving his farm to obtain the best price he could for yielding up his possession. The "free sale" of this right of tenancy was restricted only in so far as that it must be to one person only (except under agreement with the landlord) that the landlord might object on sufficient grounds to the person purchasing, and that he also had the right of pre-emption. At the expiration of the 15 years the landlord might resume possession of the holding on paying the tenant compensation for improvements effected by him, and also paying him the value of his tenant-right, both being determined by the court should the parties be unable to agree. A tenant who sold his tenant-right on quitting his holding was not to be entitled to compensation for disturbance, or if he had received compensation he was not entitled at that time to sell his tenancy. A tenant holding under the Ulster tenant-right might sell under that or under this system, but not partly under one and partly under the other. The scale of compensation for disturbance of tenancy was fixed as follows: Where the rent was \$146.70 or under, a sum not exceeding 7 years' rent; rent from \$146.70 to \$244.50, not exceeding 5 years' rent; from \$244.50 to \$489, not exceeding 4 years' rent; from \$485 to \$1,467, not exceeding 3 years' rent; from \$1,467 to \$2,445, not exceeding 2 years' rent; above \$2,445, not exceeding 1 year's rent. The act also empowered the land commission to advance loans to tenants not exceeding three fourths of the value of their holdings, to enable them to become proprietors, and such loans were repayable by an annual payment of 5 per cent for 35 years. Provision was also made for assisting emigration. A tenant whose holding, or the aggregate of whose holdings, were valued at not less than \$733.50, was entitled by writing to contract himself out of any of the provisions of this act, or of the act of 1870. Another act passed in 1887 extended the privileges conferred by the act of 1881, and a

third act passed in 1896 went farther in the same direction. The Purchase of Land (Ireland) Act of 1891 supplied the Land Commission with further funds for advances to tenants to enable them to purchase their holdings. But the Land Purchase Act of 14 Aug. 1903, whereby the tenants may buy the farms and become independent of the landlords, is a great beginning toward a readjustment of agricultural conditions. The new law provides that the actual tenants or persons, or persons who have been tenants within 25 years, may purchase all the land they occupy or desire at prices varying according to the condition of the property, to be paid for upon the installment plan, the seller accepting a mortgage for a term of years, the government guaranteeing the payment at the ruling rate of interest. The law is not compulsory; landlord and tenant may arrange matters.

Stock-raising has increased in importance during late years. Statistics show that there are now in Ireland more cattle, in proportion to area, than in any other country of Europe. The following table will show the changes which have taken place since 1900:

YEAR	Horses	Cattle	Sheep	Pigs
1900.....	491,156	4,608,550	4,386,876	1,268,521
1901.....	491,430	4,673,323	4,378,750	1,219,135
1902.....	509,284	4,785,204	4,215,740	1,372,592

England is the principal market for the cattle raised in Ireland. The breeds of horses vary with the locality; ponies are numerous in Connaught; hunters in the north of Leinster; and draft horses in nearly all the counties on the eastern coast. Much good has been effected by co-operative societies. The number of co-operative organizations in 1901 were as follows: 106 agricultural societies, 187 dairy and agricultural societies with 81 auxiliaries, 29 poultry societies, 103 co-operative banks, 46 miscellaneous societies, and 2 federations. The membership of the whole was 51,000.

Manufactures and Trade.—The linen manufacture early took root in Ireland, and still continues to be its most important staple; and in every article, except lace and cambric, competes successfully with all other countries. It has increased in a remarkable manner within the last 40 or 50 years, and Belfast, its centre, has now become the first city of Ireland in population as well as in manufacturing industry. The linen manufacture, indeed, is of importance; a large number of the factories are in Ulster. The cotton manufacture has had a very different history, the number employed in this industry having declined from 4,000 in 1868 to 800. The woolen manufacture appears at the outset to have outstripped that of linen. It had at least made such progress as to alarm the woolen manufacturers of England, who, in a spirit of petty jealousy, petitioned the English parliament for its discouragement, and succeeded. The Irish were prohibited from sending their woolens abroad, and could not even send them into England without paying an oppressive duty. Had the manufacture been suited to the country it might have surmounted all this absurdity and injustice; and, at all events, when these ceased to operate, would have revived. But the woolens of Ireland continue to be of very secondary importance, and indeed the manufacture seems to have much decreased in recent years. The tweed has retained its popularity. The manufacture of Irish poplins (of woolen and silk, or woolen and flax

IRELAND

or cotton) is very flourishing. The number of textile factories in 1890 was 263, which employed 71,788 persons. There are about 20 mills engaged in paper-making. The brewing of porter and distillation of whiskey form important items in the national production. The making of shirts and other clothing for men is becoming prominent. Ship-building was begun several years ago, and during the last of the 19th century it became quite prominent. The largest ship-building yards are in Belfast, where about 10,000 men and boys are employed. The ships of the White Star line are all built in Belfast. Ship-building is carried on to some extent at Dublin, Londonderry, and Haulbowline. Home work still flourishes; and the Irish hand-made laces and embroideries are still popular.

Commerce.—That of Ireland is not at all proportioned to her natural capabilities, and to the admirable facilities afforded by the excellent harbors situated on her coasts. The laws made by the British government to destroy the commerce of Ireland account in a large measure for the present condition of trade. The most important articles of export find a market in Great Britain. They consist chiefly of grain and flour, live stock, salt and fresh meat, eggs and butter. Manufactured articles, particularly linen, rank next in importance; but as the bulk of such articles is very small in comparison with their value, the trade, or at least the shipping connected with them, holds only a secondary place. The trade with foreign countries is also considerable. The principal imports are colonial produce, woolen and cotton goods, wheat, wool, coal, and salt. Of the shipping employed in this trade only a mere fraction is Irish. Belfast and Dublin are the chief shipping ports. The value of the exports direct from Ireland to foreign ports was about \$4,533,000 in 1883, of imports from foreign parts \$53,166,620; in 1900 they were \$6,560,240 and \$50,072,985, respectively. In 1900 the number of vessels entered from the colonies and foreign parts was 1,048 (1,032,109 tons); and cleared 448 (473,758 tons); entered coastwise 31,069 (6,401,172 tons); cleared 31,026 (6,746,328 tons).

Transportation.—The rivers of Ireland form excellent navigable channels. In several of them, however, when the water was low, the navigation became seriously impeded by rocky shoals. In removing these, or in making artificial cuts for the purpose of avoiding them, vast sums have been expended. Improvements of equal importance have been made by the construction of canals; but since the introduction of railroads, canals have in Ireland, as elsewhere, sunk to a position of secondary importance. The principal canals are the Grand Canal, 165 $\frac{3}{4}$ miles in length; the Royal Canal, 96 $\frac{1}{4}$ miles; the Barrow Navigation, 42 $\frac{1}{4}$ miles; the Newry Navigation, 35 miles; the Lagan Navigation, 26 $\frac{1}{4}$ miles. With the exception of the Barrow Navigation, the Grand Canal, and the Lagan Navigation, the dividends paid by the Irish canals in the possession of public companies are almost nominal. The Royal Canal yields a profitable return, but it is merged in the Midland Great Western Railway. The Grand and Royal canals connect the important systems of the Shannon Navigation, in all 158 miles in length, with Dublin. The railroad system of Ireland has attained a considerable development. The roads are all constructed on a gauge of 5

feet 3 inches, which is compulsory. The average cost of construction, including carrying stock, is about \$80,000 per mile. The principal railroads are the Belfast and Northern Counties Railway, with a total length of 180 miles; the Dublin, Wicklow, and Wexford Railway, 135 miles in length; the Great Southern and Western, 478 miles; the Midland Great Western Railway, 425 miles (including the Dublin and Meath, Great Northern and Western, etc.); the Great Northern of Ireland, 503 miles (including the Dublin and Belfast Junction, 63 miles, and the Ulster Railway, 140 miles); and the Waterford and Limerick Railway, 141 $\frac{1}{4}$ miles, or including the lines of other companies worked by it, 269 miles in length. Few of the Irish railroads pay any dividend at all; but those that do pay represent a large proportion of the capital invested in railroads in Ireland, and some of them are very remunerative concerns. The most profitable of them are a short one connecting Dublin with Kingstown, the Belfast and Northern Counties, and the Ulster Railway. The total length of railroads completed and open for traffic 1 Jan. 1902 was 3,208 miles. The total number of passengers for that year was about 28,000,000, the total amount of minerals and general merchandise carried, about 5,300,000 tons; the total receipts from the carriage of passengers and goods amounted to nearly \$20,000,000.

Public Works.—Large sums have been advanced in loan by the sanction of the imperial parliament under various acts for public works and improvements in Ireland. The Irish board of public works has charge of such grants and their expenditure; the objects to which they are applied include landed improvements and drainage, fishery piers and harbors, roads, bridges, and public buildings, tramways, light railways, and certain lines of inland navigation, and the preservation of ancient monuments. The commissioners have authority to lend for the purpose of any work for which county or borough councils are authorized to borrow. Of \$121,141,190 of loans advanced for purposes that have not yet been fully carried out ("current services"), \$67,655,395 have been repaid, besides interest amounting to \$35,707,115, while the sum of \$7,985,250 has been remitted. The largest item of this expenditure, namely, \$26,196,100, has been spent on the improvement of lands; river drainage and navigation have absorbed some \$14,837,500, while on lunatic asylum buildings there has been spent \$13,101,925; in schemes for the improvement of public health, \$13,451,390; under the Laborers' Acts, \$9,150,940 (to provide employment, etc.); on railways, \$6,000,635; in advances to occupants for improvement of holdings, \$5,355,530; roads and bridges, \$5,041,220. Other sums have been spent on harbors and docks, reclamation of lands, dwellings for the poorer classes, teachers' residences, dispensaries, and in advance to tenants for the purchase of their farms. The recent Land Purchase Bill has made available a large sum of money to be used in aiding tenants in purchase of holdings (1903).

Money, Weights, Measures.—The standard of value is gold. Silver is legal tender up to 40 shillings; bronze up to 12 pence; and farthings only to 6 pence. Bank of England notes are legal tender. The names of the coins used are sovereign, half-sovereign, crown, half-crown, florin, shilling, sixpence, threepence, penny, half-

IRELAND

penny, and farthing. The standard units are: of weight, the pound, 7,000 grains; of length, the yard; of capacity, the gallon, containing 10 pounds avoirdupois of distilled water at 62° F., the barometer at 30 inches. On these units all other legal weights and measures are based.

The sovereign weighs 123.274 grains, and contains 113.001 grains of fine gold. The shilling weighs 87.27 grains, and contains 80.727 grains of fine silver. Bronze coins consist of a mixture of copper, tin, and zinc. The penny weighs 145.83 grains.

Banks.—The institution known as the Bank of Ireland has a royal charter and unconditional liability. This bank manages, free of charge, all the public debt of Ireland, and, like the Bank of Scotland, it loans money to the British government, for which, since 1865, 3 per cent is paid. In 1902 there were in Ireland nine joint-stock banks with 625 branches, all of which had adopted limited liability. Six of the nine banks were note-issuing.

There are two kinds of savings banks in Ireland: one the trustee savings bank, which has been in existence since the first years of the 19th century; the other, the postal savings bank, which was begun in 1861. The annual amounts which may be deposited by each person are regulated by the Savings Bank Act. According to the act for 1893 the amount which may be deposited in one year by one person is £50, or \$244.50, and not £30, or \$146.70, as was the law under a former act. The amount of stock which may be purchased was raised from £100, or \$489, to £200, or \$978, and the increase in the stock-holding limit was changed from £300, or \$1,407, to £500, or \$2,445. The post-office savings banks are considered more secure than the trustee savings banks, and the deposits in the former are some larger than in the trustee savings banks. The trustee savings banks received in 1897 about \$23,044,180, and in 1902 about \$23,547,910. The postal savings banks received in 1897 about \$10,869,735, and in 1902 about \$12,208,705.

Charities.—The Poor Law, which regulates the system of public charities, is about the same for Ireland as for England and Scotland. It provides for relieving the needy in their own homes or for placing them in charitable institutions. The law is administered by the local government board through boards of guardians elected for the purpose. The number of indoor poor who received assistance for the year 1902 was 43,531; the number of outdoor poor for the same year was 57,813; and those in asylums, 1,427. A large amount of aid is dispersed through private means; but a strong effort is being made to remove the causes, which are about the same in all countries, and which usually result in poverty. Efforts have been made to improve the methods of work, and to foster habits of economy.

Government.—Ireland, by the Act of Union, became an integral part of the United Kingdom, and shares in its legislation by means of 28 representative peers in the House of Lords, and 103 representatives in the House of Commons. The representative peers are elected for life by the whole body of Irish peers. The Lord-Lieutenant, who represents the sovereign, holds his court in the castle of Dublin. Since 1898 great changes have been made in the manner of administering the local government. Previous to that date the chief authority in the county was

the grand jury, and all local affairs pertaining to the government and local laws were attended to by the grand juries and presentment sessions. The act of 1898 provides for a council, elected by the people, for a term of three years. The government of the boroughs, rural and urban districts, is also vested in an elective council. The unincorporated boroughs are governed by commissioners.

The government of the incorporated boroughs is vested in a mayor, aldermen, and council. The large cities are now county boroughs. The chief secretary, the under-secretary, and four commissioners, who are appointed by the Lord-Lieutenant, constitute the local government board, which has supervisory authority over the local council. This board approves or rejects nominations made by the local authority, decides upon salaries, and has the whole local government in charge to a certain extent.

The judiciary of Ireland is similar in many respects to that of England. The highest tribunal is the Supreme Court of Judicature, composed of the High Court of Justice and the Court of Appeal. Other courts are the Court of Bankruptcy, the Land Commissioner's Court, and the High Court of Admiralty. The English municipal law is administered by the courts of Ireland.

Finances.—In addition to local indebtedness Ireland assists in the liquidation of the national debt of the kingdom. The amount which has been apportioned to Ireland, it is claimed, is larger, in proportion to the wealth of the island, than the amount apportioned to England and Wales. The imperial revenue collected in Ireland for the fiscal year ending 31 March 1902 was about as follows: Customs, \$15,500,000; excise, \$15,850,000; estate and duties, \$317,300; stamps, \$15,740,000; income tax, \$5,822,000; post-office, \$3,697,000; telegraphs, \$876,200; crown lands, \$103,400; miscellaneous, \$574,200; making a total, together with the non-tax revenue, of \$46,792,000. The local taxation revenue for the same year was about as follows: Customs, \$74,850; excise, \$635,000; estate and duties, \$995,000. The expenditures for the same year were about as follows: Against exchequer, for the civil government, \$22,200,000; for collection of taxes, \$1,215,000; post-office, \$5,435,000. For local taxation accounts paid the same year, \$5,275,000. The whole makes a grand total of about, for imperial revenue, \$284,125,000; for local revenue, \$1,945,000. The total amount raised for local expenditure was distributed about as follows: For water, gas, electric lights, \$12,270,820; tolls, dues, \$1,913,560; rents, interest \$1,229,225; government contributions, \$7,810,780; loans, \$2,365,800; miscellaneous, \$2,103,685. The chief local expenditures were about as follows: Town and municipal authorities (police, sanitary works, etc.), \$8,025,450; unions, poor relief, \$5,592,420; county, rural sanitary, and road authorities, \$9,591,165; harbor authorities, \$2,422,620.

Population.—Since the census of 1841, when the inhabitants of Ireland numbered fully 8,000,000, the population has almost steadily decreased. In 1846-7 a frightful famine, occasioned by the potato disease, broke out, and was followed by a visitation of fever and cholera. The population was in consequence greatly reduced, and since then emigration has taken the place of

IRELAND

penny, and farthing. The standard units are: of weight, the pound, 7,000 grains; of length, the yard; of capacity, the gallon, containing 10 pounds avoirdupois of distilled water at 62° F., the barometer at 30 inches. On these units all other legal weights and measures are based.

The sovereign weighs 123.274 grains, and contains 113.001 grains of fine gold. The shilling weighs 87.27 grains, and contains 80.727 grains of fine silver. Bronze coins consist of a mixture of copper, tin, and zinc. The penny weighs 145.83 grains.

IRELAND

famine and disease in reducing it further. The extent of this emigration will be gathered from the following statement of the numbers that left the country between 1851 and 1899:

PROVINCES	Number of Emigrants between May 1, 1851, and Dec. 31, 1898.		
	Males	Females	Total
Leinster	355,104	320,706	675,810
Munster	673,106	640,092	1,313,198
Ulster	590,314	475,761	1,066,075
Connaught	282,532	306,616	589,148
Not specified	61,766	48,902	110,668
Total	1,962,822	1,792,077	3,754,899

From the causes just referred to the total population of Ireland, which might by natural increase have amounted to at least 10,000,000, had dwindled away to 4,425,597 in 1902.

The population by provinces in 1901 was as follows: Leinster, 1,152,829 (150.1 per square mile); Munster, 1,076,188 (112.3 per square mile); Ulster, 1,582,826 (183.8 per square mile); Connaught, 646,932 (94.5 per square mile). In that year the average population per square mile for Ireland was 136.7. In 1901 there were six county boroughs with populations as follows: Dublin, 290,638; Belfast, 349,180; Cork, 76,122; Limerick, 38,151; Londonderry, 39,892; Waterford, 26,769.

Education.—The present difficulties in establishing a public system of education in Ireland had their origin in the times following the efforts to make the people abandon the Roman Catholic Church. As a consequence, the parents refused to patronize the government schools. The laws of the time of William III. and Queen Anne made it a crime for Catholics to teach or to have their children taught by Catholics, or to send them abroad where they would be educated in Catholic schools. The rigid enforcement of these laws resulted in a large proportion of illiteracy among the Roman Catholics, although they had established schools abroad which were attended by those with wealth sufficient to live in a foreign country. (Consult, 'History of Irish Schools and Scholars of the Middle Ages.') The principal educational institutions in Ireland are Dublin University and the three Queen's Colleges. The Queen's Colleges were formerly connected with an examining and degree-conferring body, Queen's University, for which the Royal University of Ireland was substituted in 1882, in pursuance of the University Education (Ireland) Act, 1879; \$100,000 being yearly granted from the surplus funds of the Irish Church (q.v.). The Queen's Colleges, however, are not directly affected by this act. The Royal College of Science for Ireland was established under the authority of the Science and Art Department, London, in August 1867. Its object is to supply a complete course of instruction in science applicable to the industrial arts, and to aid in the instruction of teachers for the local schools of science. There are professors of physics, chemistry, botany, zoology, agriculture, mining, geology, applied mathematics, etc. The course of instruction extends over three years. There are also the General Assembly's Theological College, Belfast; the Magee College,

Londonderry, a Presbyterian college opened in 1865, and embracing in its curriculum literature, science, and theology; the College of St. Columba, near Dublin, founded for the purpose of establishing a system of instruction preparatory to the university.

The Catholic University of Ireland, established in 1854, grants degrees in theology and philosophy, and since 1882 sends its students to the Royal University for examinations for degrees in arts, medicine, law, and engineering. Affiliated with the Catholic University, and now a part of it, are the following colleges: St. Patrick's, Maynooth; University College, Dublin; University College, Blackrock; St. Patrick's, Carlow; Holy Cross, Clonliffe; and School of Medicine, Dublin. There are additional, in different cities and towns, about 40 Roman Catholic colleges and seminaries for men, and a large number of academies or secondary schools for women. There are numerous non-sectarian schools, some of them of royal and private foundation and endowed, but the most prominent are those established since 1831 under the superintendence of the commissioners of national education. These schools are open to the children of parents of all denominations. The pupils are not required to attend any religious exercises or religious instruction of which their parents or guardians disapprove, and opportunity is given to pupils of each religious persuasion to receive separately at appointed times such religious instruction as their parents or guardians may approve of. Of these schools there were 8,670 in operation in 1899, with 785,139 pupils on the rolls. The average daily attendance was small, being only 513,852. In 1892 an act was passed by which a beginning was made of free education, and a modified system of compulsion. In 1878 an act was passed for the promotion of the intermediate secular education of boys and girls in Ireland. By this act about \$5,000,000 from the Irish Church surplus fund was set apart, being invested in commissioners who are to apply the revenue arising from it to the purposes of the act, these being (1) the carrying on of a system of public examinations; (2) the awarding of exhibitions, prizes, and certificates to students; and (3) the payment of results fees to the managers of schools fulfilling certain prescribed conditions. The schools referred to in the act are of a grade superior to the national schools. The subjects of examination are Latin and Greek, modern languages, Celtic, natural science, mathematics, etc. The system of apportion according to results is no longer in use; instead the amounts awarded are based on average attendance.

Considerable attention is given to technical instruction. In all the convent schools the young girls have regular courses in domestic science, and in several trades are taught. The Department of Agriculture and Technical Instruction has an advisory board of technical instruction. In 1901-2 the course of experimental science had been adopted in 152 schools with 6,412 science pupils. The central institutions belonging to this department are the Royal College of Science, Dublin, and the Metropolitan School of Art. Throughout the provinces the work is being organized by the councils of county boroughs, urban districts, and counties. The annual grant for the technical instruction is \$25,895,000. Provisions are made for the

IRELAND

special training of teachers for the different departments of work.

Language and Literature.—The predominant in the Irish literature is the heroic, pathetic, love of nature, romance, virtue, and through all runs the traditional. Although the Ogham, a system of writing, was introduced into Ireland about 13 centuries before Christ, yet the literary productions were transmitted orally. Hyde says, "The love of literature of a traditional type, in song, in poem, in saga, was more nearly universal in Ireland than in any other country of western Europe."

The modern literature of Ireland, or the literature produced by Irish writers of the last centuries, has been included under English literature because the language used is English. See CELTIC LANGUAGES.

Music.—See IRISH MUSIC.

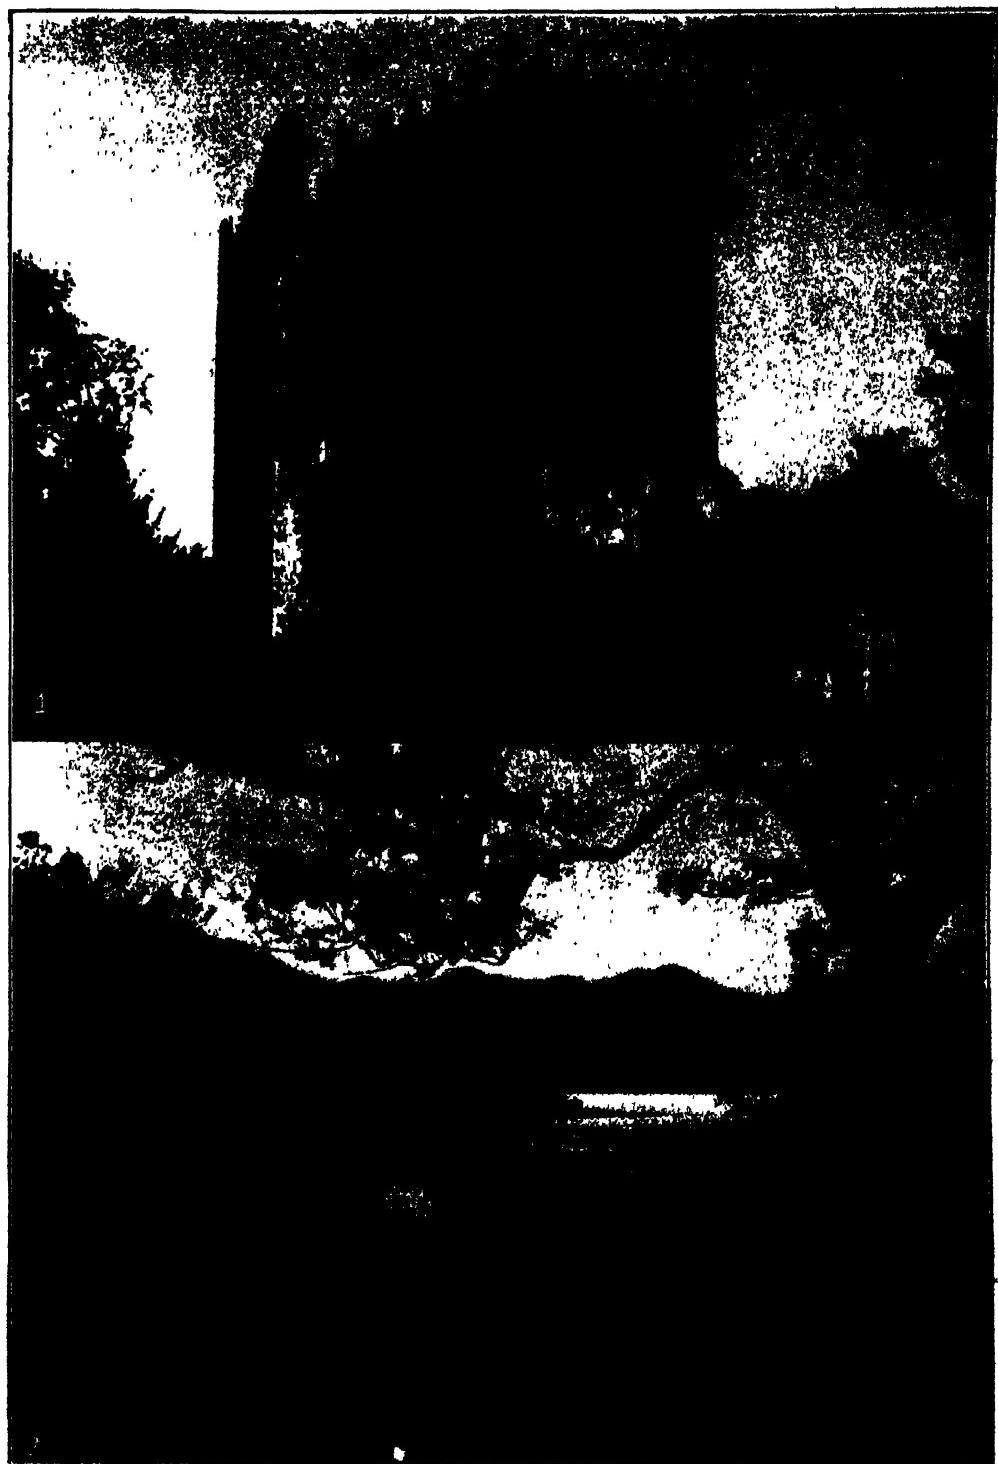

Art and Architecture.—Many of the ancient types of architecture extinct in other lands may still be found in Ireland. Their buildings and home life remained practically undisturbed for centuries; no ancient Roman architecture is found on the island. When Christianity was introduced, the change in form of the Druid temple was for several centuries in accordance with the natural development of the people, except the addition of the small cross, the windows facing the east, and the altar. When the building became too small a new one was erected beside it. Some of the existing ancient specimens are a group of stone buildings on Skellig Michael, a rock rising precipitously out of the sea to the height of 700 feet, and about eight miles due west of the nearest headland in the County Kerry. The approach is by a flight of stone steps. Dry rubble masonry forms the walls, and in this group, as in others, the absence of the arch shows its ancient origin. It is oval outside, bee-hive in form, but rectangular within. The door has a horizontal lintel, above which is a small cross worked into the stone wall. The six cells in the interior, the common room for prayer (choir), the chapel, all show it was occupied by monks. The doors, with inclined jambs and horizontal lintels, antedate the arch. A wider lintel above, or the double lintel, indicates progression in architecture, a method of relieving the pressure of the roofs. The roofs of the ancient buildings were of stone. There are many of these ancient ruins, some in a good state of preservation. Off the coast of Sligo, at Inishmurray, on the Isles of Aran, on islands off the coast of Kerry, and in many places are found buildings of dry rubble masonry. The change shows itself when cement is used and the walls become perpendicular, as at Gallarus, in Kerry, and a further advance is shown in St. Declan's oratory in Ardmore, with square perpendicular towers, or, more properly, supports at the corners. Some of these were erected in the 6th, 7th, and 8th centuries. St. Colum-Cille's monastery at Kells was built about 807 A.D. In the 'Annals of the Four Masters' mention is made of the church St. Kevin founded in about 1108, and which is still in existence, at Glendalough. The Romanesque style makes its appearance in the 11th century; the earliest example is in St. Flannan's, at Killaloe. Brian Boroiomhe is said to have built churches at Killaloe, in County Clare. A church built about this time, at Freshford, the ancient Achadh-ur, eight miles northwest of Kilkenny, is still in use. At

Clonfert Cathedral, in County Galway, there is a fine example of an Irish Romanesque doorway. This church is said to have been founded by St. Brendan, "the navigator." The interlaced patterns on the piers, the ornamented column, are all most beautiful. "There is not," says Mr. Brash, "a square inch of any portion of this beautiful doorway without the mark of the sculptor's tool, every bit of the work being finished with the greatest accuracy." The Cathedral at Ardmore, County Waterford, shows another advance in its decoration; here may be seen The Judgment of Solomon, Adam and Eve, The Magi bringing their gifts, the stable indicated by a cow, etc. Many of the modern cathedrals are most beautiful.

The "Round Towers" of Ireland have been for years subjects of study and discussion. There exist in Ireland in whole or part about 100 of those towers; 18 are in a perfect condition. Many claim that the Round Towers are of pre-Christian origin, and cite the similar towers, two in Scotland, seven on islands off the coast, one on the Isle of Man, and a few on the Continent, as examples of pagan architecture. Their average size is 100 feet in height, circumference at base, 50 feet, walls at door lintel, 3½ feet. The interior is divided into from four to eight stories. Petrie, who has studied the subject with care, claims that the towers are of Christian origin and were used both as bell towers and as safes or places in which to deposit the Church treasures. The Irish name for the towers, *Cloigthcach*, which means "house of a bell," supports the theory of Petrie and others. Petrie advances other and strong arguments in support of his theory. The 'Annals of the Four Masters' mentions the bells in some of the towers. One of the finest examples of a Romanesque doorway in a Round Tower is at Kildare. Some of the ancient pottery shows skill and artistic merit. In designing and coloring the ornamentation of the old Celtic manuscripts show great artistic power. The initial letters are most beautiful, especially in the 'Book of Kells,' a copy of the four Gospels in Latin, and in 'Annals of the Four Masters.' The symbolism used by other early nations is not found in the works of the ancient Irish. The designs are geometrical patterns, interlaced ribbon work, diagonal and spiral lines, strange animals, peculiar birds, and the key pattern. The ancient metal work shows unique and beautiful designs; the bell shrines, the brooch of Tara, and many pieces of old metal work may be seen in museums. The laces of Ireland, revived the last of the 19th century, show most intricate and charming patterns. Sculpture and oil painting are modern arts in Ireland, and in both many of Irish birth have excelled.

Religion.—The first authentic account of the introduction of Christianity into Ireland was in the 5th century, when Pope Celestine sent Germanus, bishop of Auxerre, and later, in 431, Palladius as bishop. Both Germanus and Palladius found on the island believers in Christianity, but no organized body of Christians. However, the chief work of conversion and organization was accomplished by St. Patrick, who, good authorities state, was sent to Ireland by the same pope. Killpatrick, a town of Scotland, is said to have been Patrick's birthplace, but some authorities claim that he was a native of France. He had been consecrated bishop

IRELAND.

1. Blarney Castle.

2. Innisfallen, Lake Killarney.

IRELAND

before coming to Ireland as a missionary, and he selected Armagh as his see. A large number of converts were made, so many that even before Patrick died he had other bishops and a number of priests to assist him. The Roman Catholic Church in Ireland has four archdioceses and 25 dioceses. The archdioceses are Armagh, Dublin, Cashel, and Tuam. The Roman Catholic clergy and churches are all supported by voluntary contributions. The college at Maynooth, for the education of those studying to become priests, was founded in 1795. There are several other Roman Catholic ecclesiastical seminaries and colleges.

The Reformation never made much progress in Ireland, and though a Protestant Episcopal church was established by law, it was only the church of a small minority. In 1869 it was disestablished. Previous to this time the clergy were supported by a tithe rent-charge, the proceeds of the Church lands, etc., the total annual income of the Church, including the value of houses and lands in occupation, being about \$3,068,920. By the above act, taking effect from 1 Jan. 1871, the position of the Church and clergy was entirely changed, though those holding benefices at the time of its passing have not suffered loss. The property and tithes formerly belonging to the Church are now vested in commissioners, who pay to all deprived of income by the act, so long as they continue to discharge the duties of their offices, such an annual sum of money as they would otherwise have received, deduction being made of curates' salaries, and other outgoings to which the parties would have been liable, and regard being paid to the prospective increase of incomes by the falling in or cessation of such charges; or instead of an annual sum, an equivalent single payment has been paid to such as have commuted their claims in that manner. The Irish Church accordingly is no longer a state Church, and none of its bishops have now a seat in Parliament. It is still a vigorous and flourishing institution, however, and possesses funds amounting to over \$40,640,000. Of this, upward of \$20,000,000 have been voluntarily contributed by friends of the Church since it was disestablished. While disestablishing the Irish Church, the act at the same time declared the cessation of the Maynooth grant and the *Regium Donum*. The affairs of the Irish Church are now managed by the diocesan synods and by the general synod in conjunction with the representative body. The supreme legislative powers reside in the general synod, which meets in Dublin, and is composed of the archbishops of Armagh and Dublin and the 11 bishops, and of lay and clerical representatives from the different dioceses; the lay representatives being more than twice as numerous as the clerical. The representative body incorporated in 1870 consists of the archbishops and bishops *ex officio*, 39 lay and clerical elected members (three for each diocese), and 13 co-opted members elected by the other two classes conjointly. This body is empowered by its charter to hold Church property, subject to the regulations of the general synod. The Church uses the Book of Common Prayer, as revised in accordance with statutes passed by the general synod, and furnished with a preface containing an exposition of its formularies in the sense in which they are understood by the Church.

Vol. 9—9

The Presbyterian Church of Ireland is chiefly confined to the province of Ulster, where it may be said, more especially in the counties of Down and Antrim, to be the leading religious denomination. Its ministers are supported by voluntary contributions, seat-rents, and church funds. They were formerly aided by an annual grant from government, called the *Regium Donum*, the amount of which, paid in 1869, was \$202,735. This annual grant, however, was abolished, as already mentioned, by the Irish Church Act of 1869, and was commuted to a single sum of \$3,506,860 paid to the Church. According to the census of 1901 there were in Ireland 3,310,028 Roman Catholics, 579,385 Protestant Episcopalians, 443,494 Presbyterians, 61,255 Methodists, and 56,703 members of other persuasions, besides 3,769 Jews.

History.—The beginning of the history of Ireland is, like that of all European nations, enveloped in fable. Among the ancients it was known at least as early as the time of Aristotle, who calls it *Ierne*. In Diodorus Siculus it is called *Iris*; in Strabo, *Ierne*; in Pomponius Mela, *Iverna*; in Pliny, *Hybernia*. Plutarch calls the island *Ogygian*, meaning very ancient, and says: "They drew their history from remote antiquity, so that of other nations is new compared with them." Yet the information to be found about Ireland in the works of the ancient geographers and historians is altogether very scanty. The bardic historians of the country speak of Greek and Phoenician colonies, and lists of kings, for which there is no authentic, but some probable, foundation. The vernacular language of the Irish proves that they are a part of the great Celtic race which was once spread all over Western Europe. The first probable records of the Irish people show that for the times they were advanced in civilization. The ancient bards were called *Filcas* or *Feardanos*, which means philosophers. Cæsar mentions in his 'Gallic Wars' their advancement. Pliny, Cæsar, and other authors say that the Druids who inhabited Ireland were learned; they knew philosophy and the sciences. In the Irish chronicles we find that in the reign of Eochy the First, more than a thousand years before the birth of Christ, "society was classified into seven grades, each marked by the number of colors in its dress, and that in this classification men of learning, that is, eminent scholars, were by law ranked next to royalty." Another proof of the existence of an ancient civilization, marvelous for its time, was the institution of Feis Tara or the Triennial Parliament of Tara. The monarch, Ollav Feola, who reigned as Ard-Ri, or monarch, of Erinn, about 1,000 years before Christ, established this parliament. The subordinate royal princes or chieftains, constituted one branch; the Ollavs or law-givers, and bards, judges, scholars, and historians, another branch; and the third consisted of the military commanders. Under the Ard-Ri, or monarch, were the kings of the provinces, and under each king were the clans who were governed locally by a chief, each clan selecting its own. Wars were frequent, as fighting and bloodshed were common pastimes throughout the then known world. The battle was the final court of appeal, and in most instances the first court of trial. A cause of dissension in Ireland, as in Great Britain and other countries, was the antagonism

IRELAND

existing among people of different races. The Milesians, the Tuatha de Danaans, and the Firbolgs (q.v.) were distinct races centuries after the Milesians landed in Ireland. The differences among themselves seem not to have seriously affected their union when attacked by a common foe; as at the birth of Christ, when Rome was mistress of nearly all of Europe, she had never gained possession of Ireland. The introduction of Christianity into Ireland was not attended with bloodshed as in many other countries; indeed, afterward the nation seems to have enjoyed a season of repose from strife, although southern Europe was being overrun with the Germanic hordes. This repose favored the growth and expansion of Christianity and the progress of learning. The schools and monasteries founded by Saint Patrick and his bishops in the 5th century became the centres from which went forth many scholars; and even as early as the 6th century, Ireland became the seat of western learning; and its monasteries were the schools from whence missionaries who disseminated the Christian faith throughout continental Europe proceeded. In the 8th and 9th centuries the scholars of Ireland were among the most distinguished at the courts of the kings, especially at that of Charlemagne, but when the Northmen commenced their descents some of the schools were destroyed and the monks dispersed. The ravages of the Danes at this period had results different from the attacks of the Romans. The continued attacks for nearly two centuries fostered internal dissensions, when in the beginning of the 11th century Brian Boromhe (Brian of the Tribute) united the greater part of the island under his sceptre, restored public tranquillity, and subdued the northern invaders. After a contest of about 20 years he conquered Malachy, the brave warrior who "wore the collar of gold" won from the Danish invader, and became Ard-Ri of all Erinn. After the death of Brian, the island became a place of dissension; frequent wars rendered them weak against a foreign foe. This condition was largely the result of the divisions, made by Brian, of the island among his three sons. At this time Henry II. of England, professing love for Ireland and a great desire to restore peace, sought to gain possession of the island. This was the beginning of the Anglo-Norman invasion of Ireland. Henry II. claimed to have received from Pope Adrian IV. a bull authorizing him to take possession of Ireland. (The authenticity of this bull is very doubtful.) After some delays occasioned by internal troubles in England, Henry attempted to gain possession of Ireland. For many years after, the history of Ireland was a record of persecution, confiscation of lands, and attempts to wrest from the people inalienable and hereditary rights. So great was the resistance that in the 14th century, at the time of Richard II., the authority of England extended practically over only a small portion of country on the eastern coast, called "The Pale" (q.v.). This was governed by various nobles subject to a viceroy. The subjection was, however, sometimes little more than nominal. The nobles quarreled among themselves, and were very often at open feud. The beginning of the reign of Edward III. (1327) was marked in Ireland by the outbreak of civil strife in every part of the English "Pale," advantage of which was taken by the

Irish for a general rising, which threatened the safety of the English colonists, and which the government found itself unable to subdue, until it yielded to the demands of the barons in Ireland, by granting them complete civil and military jurisdiction in their own districts. During the wars with France some Irish troops served in the English armies, and the common sympathies induced by that circumstance seemed likely to promote a better state of feeling between the two races, when the breach was made wider than ever by the celebrated statute of Kilkenny (1367), framed under the viceroyalty of Lionel, duke of Clarence, son of Edward III., forbidding, under severe penalties, intermarriages between English and Irish, the assumption of Irish names by persons of English blood, the use of the Irish language, the native (Brehon) law, etc. In consequence of this the disturbances between the Irish and English inhabitants of Ireland increased so greatly that the English viceroy found it necessary to protect The Pale by payments of money to the Irish chiefs, and this state of matters continued during the reigns of Richard II., Henry IV., and Henry V., until, in that of Henry VI., when Richard, duke of York, was appointed governor of the island, who succeeded by his politic measures in restoring peace. In the reign of Henry VII. (1495) was passed Poyning's Act (so called from Sir Edward Poyning, lord-deputy of Ireland), which provided that all former laws passed in England should be in force in Ireland, and that no Irish Parliament should be held without previously stating the reasons on account of which it was to be summoned, and the laws which it was intended to enact. The power of the English government in Ireland was thus strengthened, but nothing was done to improve the condition of the Irish, whom the oppressive severity of the English yoke embittered without subduing. At the beginning of the 16th century the greater part of the island still remained unconquered by the English. The Irish still lived according to their old constitution under their own chiefs. In 1541 Henry VIII. received from the Irish Parliament the title of King of Ireland; but he did nothing to extend the English sway, or to improve the social circumstances of the people. The Reformation which took place in England during this reign took but a slight hold upon Ireland even in the English districts; but the monasteries were suppressed, and the tribute to the Papal see abolished. Elizabeth's reign was marked by a series of risings, which finally terminated in a general war against England, usually called the Rebellion. Hugh O'Neil, who had been raised by the queen to the dignity of Earl of Tyrone, was the leader in this war, which, though successfully begun, ended with the complete defeat of the insurgents, and the reduction of the whole island by the English (1603). More than 600,000 acres of land were taken from the Irish chiefs, and for the most part distributed among English colonists. The reign of James (1603-25) was somewhat favorable to Ireland; the arbitrary power of some of the chieftains was restrained, and the administration of justice improved, etc.; but the means which he took to effect some of these improvements were tyrannical. He demanded from every Irish chief the document upon which he rested his claim to his property, and if it were

IRELAND

not to be found, or contained even any formal error, his lands were forfeited to the crown. Of 800,000 acres of land which in this way came into the hands of the king in the north of the island, a large share was entirely withdrawn from the Irish, and divided among Scotch or English settlers. In addition to this, the Catholics, on account of the oath of supremacy by which all public officers were required to acknowledge the king as head of the church, remained excluded from all official appointments. The Roman Catholic hierarchy established in the 5th century was still in existence. Various circumstances, led, in 1641, to an attempt to shake off the English yoke. Dr. Lintard says of this insurrection that it has been usual, for writers to paint the atrocities of the natives, and to omit those of their opponents, but that revolting barbarities are still recorded of both, and that if among the one there were monsters who thirsted for blood, there were among the other those who had long been accustomed to deem the life of a mere Irishman beneath their notice. After the death of Charles I., Cromwell was appointed (15 Aug. 1649) lieutenant of Ireland. With great cruelty, he reduced the whole country within nine months. All the possessions of the Catholics were confiscated, about 20,000 Irish were sold as slaves in America, and 40,000 entered into foreign service, to escape the severity of the conqueror. (See Drogheda.) Charles II. restored a portion of the lands, but fully two-thirds remained in possession of the English or of Irish who had become Protestants. Under James II. some changes were made; under his viceroy, Earl of Tyrconnell, Catholics were given a fair representation in Parliament. In the English Revolution of 1688, the Catholics of Ireland sided with James, and the Protestants with William III. For a time the army favoring James were fairly successful; but the landing of William in Ireland changed matters. The battle, 1 July 1690, at Boyne, won by William, proved a turning point, as it encouraged the English and in a great measure discouraged the Irish. Sarsfield's gallant defense of Limerick, the last place in Ireland that held out for James, saved that city from capture by William's troops; but on 3 Oct. 1690, the city capitulated, a treaty being concluded with Gen. Ginkel on behalf of the English, according to which the Irish were to be allowed the free exercise of their religion, as had been granted by Charles II. More than 12,000 Irish that had fought on the side of James went into voluntary exile. The Treaty of Limerick was not kept by the English, a fact which is commemorated by the name which the Irish still give to the place at which it was concluded, "The City of the Violated Treaty." By a decree of the English Parliament upward of 1,000,000 acres of land were now confiscated and divided among Protestants. In order to keep down every movement of the Catholic population, cruel penal laws were passed against those who adhered to that form of religion. By these laws the higher Roman Catholic ecclesiastical dignitaries were banished from the island; the priests were not allowed to leave their counties; no Roman Catholic could hold a public office, acquire landed property, enter into a marriage with a Protestant, etc. Such suppression and persecution naturally led to the formation of secret organizations whose object would be an

overthrow of those in power, in order to secure freedom and justice. "Whiteboys," "Levellers," and a number of kindred organizations were formed, whose methods were not always fair; but who were brought into existence by force of circumstances. All this, however, did not ameliorate the general condition of the country, and it was not till the American War of Independence taught the English government the folly of attempting to govern a people by coercion, that the severity of the laws relating to Ireland was mitigated. In 1778 the penal laws against the Catholics, although not repealed, were made much more lenient. Catholics were henceforth permitted to acquire landed property, to erect schools, and to observe their own religion under fewer restrictions. In 1783, Poynings Act was repealed.

The outbreak of the French Revolution had naturally a great effect on the minds of the Irish people. Out of a corps of volunteers which had been formed in 1779, but which had been dissolved a few years later, a society was formed calling itself the Society of United Irishmen, which included in it many Protestants, and which sought to make Ireland an independent nation. The Catholics at the same time took advantage of the embarrassment of the British government to demand equal rights with the Protestants, and the government gave in to this demand so far as to remove the hindrances which had been placed by the law in the way of Irish trade and industry, and to repeal nearly all that remained of the penal laws against the Catholics, who now received the right of acting as counsel before the court, and of entering into marriages with Protestants. When further demands were refused, the Society of United Irishmen allowed its revolutionary aims to become more apparent, and the government then determined to quell the movement by force. The Habeas Corpus Act, which had been introduced into the country in 1782, was repealed; the towns were strongly garrisoned, and the society dissolved and disarmed. But the conspirators, trusting to expected aid from France, were not discouraged. At the close of 1796 a considerable French fleet did actually appear off the Irish coast bearing 25,000 land troops, under the command of Gen. Hoche; but owing to adverse winds, and the incompetence of the commanders, it was obliged to return without having accomplished anything. The only effect of this expedition was to induce the government to take still stronger measures in Ireland, the whole of which was placed under military law. The United Irishmen were thus prevented from taking any open steps for renewing the society, but they continued to pursue their ends in secret, and devised for themselves a very skilful military organization. At its head was a directory of five men, whose names were known only to those at the head of the provincial committees. In January 1798 the society already numbered more than 500,000 members, when a treacherous member gave information regarding the society to the government, and several of the leaders were seized. In consequence of this the conspirators, not knowing the extent of the revelations that had been made, resolved to anticipate any further preventive measures on the part of the government, and rushed into premature action. In May 1798, simultaneous

IRELAND

risings took place at different parts of the island; but the government was fully prepared, and the main body of the insurgents, who made a brave fight, suffered a decisive defeat at Vinegar Hill on 21 June. Flying columns traversed the island, and checked by the most violent measures any further outbreaks. In August a French squadron appeared in Killala Bay with 1,500 men on board, under Gen. Humbert; but the British troops prevented a junction with the insurgents, so that they were soon compelled to surrender. Another French expedition which approached the Irish coast in September was overtaken and attacked by Admiral Warren, and nearly all the ships composing it were captured. Several subsequent attempts of the French were similarly frustrated.

The events of this insurrection brought the British government to form the resolution of uniting the Irish and English Parliaments, since in the state of feeling which that movement too plainly manifested as prevailing among the people, it was seen that the independence of legislation enjoyed by the country fostered the desire of political independence, and it was feared that new revolutionary efforts might thence derive a legal sanction. The first proposal to this effect which was made in the Irish Parliament was rejected with indignation. The government then resorted to bribery to secure its purpose, and \$8,000,000 was spent in buying up the rotten boroughs which had the majority of seats in the Irish House of Commons. The Irish landlords were from the first favorable to the project. By these means an act providing for the legislative union of the two countries passed the Irish Parliament on 26 May 1800, and the British Parliament on 2 July in the same year, in virtue of which the union was effected on 1 Jan. 1801. But although this measure bound the destinies of Ireland still more closely to those of England, yet it was far from putting an end to the religious and political troubles which had so long divided the two countries. In order to gain the masses the enlightened Pitt had promised a complete political emancipation of the Catholics; but the bigoted George III. could not be induced to make this concession. Enraged at this great breach of faith the Catholics in 1802 formed a Catholic Association, having for its object the accomplishment of this end; but it was not till the period of O'Connell's agitation, favored by a change of public opinion in England, that the government was induced to bring in an Emancipation Bill, which after passing both houses of Parliament, received the assent of George IV. on 13 April 1829. A new oath, which could be taken by Catholics as well as Protestants, was substituted for the one previously required from members of Parliament, and the Catholics were thus enabled to take a seat in the house. They were also allowed to fill all public offices except that of lord-chancellor.

This victory was greeted by the Irish Catholics with great joy; but they wanted more than emancipation which meant permission to hold certain offices, they wanted independence. The efforts of the national party were now directed to the repeal of the Union, for which purpose O'Connell founded the Repeal Association, which caused the Grey ministry in 1833 to bring before Parliament the Irish Coercion Bill (q.v.).

When this bill became law the Lord-Lieutenant of Ireland was empowered to forbid all assemblies of the people, and to proclaim military law throughout the island; and in order to give force to the act an army of 36,000 men, besides 6,000 armed police, was sent over. The Coercion Act was indeed soon repealed, and from 1835, under the viceroyalty of Lord Mulgrave, a better feeling seemed to be growing up between the people and the government. But when the Tories came again into power in August 1841, O'Connell began anew the repeal agitation, and with such boldness that in 1843 the authorities caused him to be apprehended on a charge of conspiracy and sedition, on which he was convicted and condemned to pay a fine and suffer imprisonment for a year. These proceedings were, however, declared illegal by the House of Lords, and O'Connell was released. Soon after the terrible famine which visited Ireland in the autumn of 1845, and still more severely in the summer of 1846, cast all other interests into the background. The spirit of the people seemed broken, and many of them sadly left their native land and by hundreds of thousands emigrated to America. In the midst of this crisis O'Connell died, and the place of the party which he led was taken by one still more advanced, which received the name of Young Ireland. In these circumstances of political excitement the French revolution, which took place in February 1848, had a great effect upon Ireland. The leaders of the Young Ireland party, Smith O'Brien, Mitchel, Duffy, Meagher, and others, entered into relations with the provisional government at Paris, and the people generally began openly to provide themselves with arms, and to exercise themselves in the use of them. But the measures of the government frustrated the designs of the conspirators. The Habeas Corpus Act was suspended, the insurrectionary newspapers suppressed, and Smith O'Brien, who had been hailed by the people as King of Munster, and a number of his associates were arrested and condemned to death. This punishment was afterward commuted to transportation. In a short time peace was restored; but the material distress remained undiminished. Famine and disease decimated the population. The agricultural holdings were deserted, whole districts remained uncultivated, and a constant and overflowing stream of emigration directed itself toward the United States.

After a time agriculture revived, and the manufacturing industries of the island began to compete with those of England. In 1849 were chartered the Queen's Colleges, offering the same advantages to Catholics as to Protestants; but these institutions have been taken comparatively little advantage of by the former. The history of those institutions made the Catholics fear they were meant as a menace to their faith. In 1852 telegraphic communication was opened with Great Britain. In 1853 an industrial exhibition was held at Dublin, resembling that held two years before in London; another exhibition was held in 1865. The latter year witnessed the discovery of a new conspiracy designed to effect a separation between England and Ireland. This had its origin in America at the time of the Civil War in the United States, when the numerous Irish in that country saw an opportunity in England's attitude toward the seceding States. This conspiracy, originating among the

IRELAND — IRETON

members of a secret society calling themselves Fenians (see FENIANS), soon spread to Ireland; but before the Fenians could take any overt action in that island their design was stifled by the proceedings of the British government (1865-6). The attention of English statesmen was now strongly drawn to the necessity of doing all that could be done to render the Irish people loyal and contented; and with this view an act to disestablish the Irish Protestant Episcopal Church was passed in 1869, and another to improve the tenure of land, in 1870. Since 1871 an agitation for what is called Home Rule has made itself prominent. In 1880 Ireland became the scene of an agitation carried on mainly by a body calling themselves the Land League. Various severe laws were passed to "coerce," but further concessions were made, and to redress Irish grievances a land act was also passed in August 1881. Under this act substantial reductions on rents were made. The Land League was suppressed, but a new body called the National League was soon organized in its place. Another act for the relief of tenants in arrear with their rents was passed, 1885. In 1885, 86 Nationalist members, headed by C. S. Parnell, were returned to Parliament, and their pressure on the government led to the production of a scheme by Mr. Gladstone, in 1886, by which Ireland was to receive a parliament of her own and the Irish members to be withdrawn from the Imperial Parliament. This scheme and the accompanying land purchase scheme were rejected by Parliament and the constituencies; and a fresh act against crime in Ireland was passed in 1887, although statistics showed the island was in a most peaceable condition, and no remarkable acts of lawlessness were being committed. In 1898 a very important Local Government (Ireland) Act was passed. It established county councils, urban district councils, rural district councils, and boards of guardians in Ireland, and transferred to them the administrative functions formerly discharged by the grand juries and presentment sessions. The first elections under the act took place early in 1899. The results showed that the voters of Ireland realized they were gaining ground. They never lost an opportunity to proclaim their discontent with the existing land laws, and their desire for "Home Rule." The Irish members of the British Parliament kept the cause of Ireland before the people; and in 1903 a further concession was gained. On 1 Nov. 1903 a new "Land Act" went into effect whereby the tenants, sub-tenants, or the people, may purchase the land and hold it as their own. Arrangements were made to assist the tenant in making the purchase.

Ireland, Language of. See CELTIC LANGUAGE.

Irenæus, i-rē-nē'ūs, Saint, one of the Greek Church Fathers: b. Asia Minor: d. Lyons, France, about 202. He was a learned and zealous man, a pupil of Polycarp and Papias. He actively opposed the Gnostics, and especially the Valentinians. His works are lost, except his 'Libri V. aduersus Hæreses,' of which there are fragments in the original Greek, and a Latin version, made, it is supposed, toward the end of the 4th century. He suffered martyrdom at Lyons, of which he was bishop, in the persecution under Septimius Severus.

Irene, i-rē'nē, empress of Constantinople: b. Athens about 752 A.D.; d. Lesbos 15 Aug. 803. In 769 she married Leo IV., after whose death, caused, as is generally believed, by poison administered by her, she raised herself (780) and her son Constantine VI., then but nine years old, to the imperial throne. When Constantine came of age he refused to permit her to participate in the government, and seven years later was arrested at the order of his mother, blinded and at last murdered. Irene was the first woman who reigned over the Eastern Empire. Her triumphal entrance into Constantinople, her liberality, the freedom bestowed on all prisoners, and other artifices employed by her, were not sufficient to secure her from the consequences of her criminal accession. She had ordered many nobles into banishment, when Nicephorus, her treasurer, who had secretly been made emperor, exiled her in 802 to the Isle of Lesbos. Her zeal for image-worship has caused her to be regarded as a saint by the Greek Church.

Irton, ir'tōn, Henry, English general and statesman: b. Attenton, Nottinghamshire, 1611; d. Limerick, Ireland, 26 Nov. 1651. He was graduated at Trinity College, Oxford, and brought up to the law; but when the civil contests commenced joined the parliamentary army,

IRIDIUM—IRISH ACADEMY

and by the interest of Cromwell, whose daughter Bridget he married in 1646, became commissary-general. At the battle of Naseby he commanded the left wing, which was defeated by the furious onset of Prince Rupert, and was himself wounded and made prisoner. He soon recovered his liberty, and took a prominent part in all the transactions which threw the Parliament into the power of the army. He had also a principal hand in framing the ordinance for the king's trial, and was one of the judges. Ireton accompanied Cromwell to Ireland in 1649, and was left by him in that island as lord-deputy. He reduced the natives to obedience with great vigor, but not without cruelty. He was buried in Westminster Abbey, and after the Restoration his body was taken up, suspended from the gallows with that of Cromwell, and buried in the same pit.

Irid'ium, a metallic element resembling platinum in its general properties, and occurring in nature in the metallic form, alloyed, usually, with platinum and osmium. The commercial supply comes chiefly from the Ural district, from Brazil, and from Borneo. Small amounts have also been obtained from California. The existence of iridium was first recognized, in 1802, by Tennant, who observed that an insoluble residue remained behind after dissolving platinum ore in aqua regia. In 1804 he showed that this residue contains two new metals, to which he gave the respective names "iridium" and "osmium." The separation of iridium from the other metals of the platinum group is a matter of some difficulty; and for details of the processes employed the more extended treatises on metallurgy and the chemistry of the metals must be consulted. Iridium is frequently obtained in the form of a spongy gray mass, or a gray powder; but by heating either of these to whiteness, and subjecting them to compression, the metal may be brought into the form of a compact, lustrous mass resembling steel. In this form it is harder than iron, and somewhat malleable when hot, though brittle when cold. At ordinary temperatures it has a specific gravity of about 22.4, being, with the exception of osmium, the heaviest substance known. Its specific heat is about 0.0323 at ordinary temperatures, and its coefficient of linear expansion (Fahrenheit) is about 0.0000039. Its melting point is very high, the estimates given by various authorities ranging from 3,600° F. to 4,500° F. Compact iridium, after being strongly heated, is insoluble in all acids, and is not affected by air or moisture. The metal has the symbol Ir, and an atomic weight of 193 if O = 16, or 191.5 if H = 1. It forms numerous salts, but these are of no practical importance. The name "iridium" (from Greek, "rainbow,") refers to the varied colors exhibited by the salts of this element, as they pass from one state of oxidation to another. Metallic iridium, either alone or alloyed with other metals of the platinum group, is used in the arts to a limited extent, where a hard, non-corrosive metal is needed. In particular, it is used for the tips of gold and stylographic pens, for the construction of standards of length, and for standard electrical resistance coils.

Iridosmine, Ir-i-dös'min, or **Osmiridium**, a natural alloy of iridium and osmium in varying proportions, is a hard slightly malleable mineral, crystallizing in hexagonal prisms. It occurs

as irregularly flattened grains, and contains some platinum, rhodium and other metals of the platinum group. It is found associated with platinum in the Ural Mountains, in South America, and elsewhere. It is also found in the black sands on the ocean beaches of northern California, and a small amount is recovered yearly by placer miners in the Sierra Nevada. Iridosmine is used to a small extent for pointing gold pens.

Iriga, ē-rē'gā, Philippines, pueblo of the province of Ambos Camarines (Sur), Luzón, on the Buhi River, 23 miles southeast of Nueva Cáceres. It is on the main road, is a military and telegraph station, and one of the most important towns in the province. Pop. 17,100.

Iris, ī'ris, in Greek mythology, daughter of Thaumas and Electra, sister of the Harpies, the fleet golden-winged messenger and servant of the Olympian gods, especially of Zeus and Hera. Iris was originally the personification of the rainbow, though she does not appear in the Homeric poems as the goddess of the rainbow. She is sometimes represented as a beautiful virgin with wings and a variegated dress, with a rainbow above her, or a cloud on her head exhibiting all the colors of the rainbow.

Iris Family, a natural order of monocotyledonous herbs, mostly perennials with tubers, corms or rhizomes, and usually with an acrid flavor. About 800 species belonging to more than 50 genera have been described from temperate and tropical climates, mostly from South Africa and tropical America. They are characterized by two rows of leaves, the outer of which fit over and protect the inner (equitant); regular or irregular perfect flowers which are frequently handsome; perianth six parted, the other floral organs in threes; and many-seeded, three-celled fruits (capsules). Some species have been used as food in countries where they are native; others furnish rootstocks which are used for making perfumes, especially orris; some few have been employed to a limited extent in medicine; but the species most widely popular are cultivated for ornamental purposes. Of these last the most important genera are *Iris* (hearts-de-lis), *Gladiolus*, *Freesia*, *Crocus*, *Tigridia*, *Tritonia*, *Sisyrinchium*, *Ixia* and *Beleamcanda*, elsewhere described.

The plants of the genus *Iris* constitute one of the chief ornaments of the northern regions of the globe, and usually grow in wet places, bearing flowers of various colors, but the prevailing tint is blue. The common wild iris or flag (*I. pseudacorus*), common in Europe and also found in the eastern United States, has yellow flowers of large size and long sword-like leaves. The gladdon or stinking iris (*I. fätidissima*) is a British species, with bluish flowers. Among favorite garden species are the English iris (*I. xiphioides*), the Persian iris (*I. persica*), the common iris (*I. germanica*), the snake's-head iris (*I. tuberosa*), and the Chalcedonian iris (*I. susiana*). Orris root consists of the rootstocks of the white-flowered *I. florentina* and some other species. Among other species found in the United States are the larger blue flag (*I. versicolor*), common from the Atlantic coast to the Mississippi, the slender blue flag (*I. virginica*), and several dwarf species.

Irish Academy, Royal, a literary and archaeological association founded in Dublin, Ire-

IRISH CATHOLIC BENEVOLENT UNION—IRISH LAND LAWS

land, in 1786. Its object is to promote the study of literature, antiquities, and science. The library founded and owned by the association contains a large number of Irish manuscripts and documents of public interest. It has a fine collection of antiquities which have been loaned to the National Museum, Dublin. The association is governed by a council consisting of 21 members. This council meets regularly several times a year. The work is divided among the members, who are subdivided into committees. The committees are three in number; committee of literature, committee of science, committee of antiquities. Students making historical research in Ireland have found this association of great assistance.

Irish Catholic Benevolent Union, a fraternal organization founded in the United States in 1869. It has 149 subordinate societies and 14,000 members. The benefits disbursed since organization have amounted to over \$2,500,000, and during the year 1902 amounted to \$45,371. The membership in the union is confined to persons of Irish extraction who are communicants in the Roman Catholic Church.

Irish Deer, or Elk. See ELK.

Irish Language, Society for the Preservation of, an organization established in 1873, in Boston, Mass. The object is to foster the study of the Gaelic language so that it may again be one of the spoken languages of the Irish people. At first the society was called the Philo-Celtic Society. The headquarters are now in Dublin, where the organization was established in 1877. It has a number of branches in different parts of the United States.

Irish Land Laws. Under the Breton laws, when the people of Ireland were divided into tribes, the land was usually the property of one of the four or five tribes which were the strongest in Erin. A large portion was given to the king or chief of the tribe, then divided among the clans that made up the tribe. Here again a large portion was given to the chief of the clan and then divided among the septs. The chief of the septs received the largest portion of the amount set apart for the sept. The free tribesmen, after the chief, received the greater part of the sept lands.

Some of the tribesmen, the Ceil, owned cattle, some, the Daer and Saer, were loaned cattle by the chief. The Fuidhir were the tenants who performed the manual labor.

When a chief died, the tribesmen distributed his land among his descendants, and when a tribesman died, the chief distributed his property. After England took possession of Ireland, the land tenure in a large part of the island continued to be administered under the Breton laws; but within "The Pale" the English feudal system prevailed; there the king alone owned the land and the tenants derived ownership from him. Gradually England forced her land laws upon Ireland. This was done by driving the "rebellious Irish" out of certain counties, Kings and Queens, then all Ulster, when the Ulster plantation was established, in 1607. Other confiscations and dispossessions took place until all Ireland came under the English law. Cromwell took forcibly the best lands of Munster and Leinster and a large part of Ulster, and divided the whole among his sol-

diers. Although some of the lands were restored later, it was retaken, by act of Parliament, under William III. Naturally the chiefs and leaders among the people of Ireland were deprived of their lands and the friends of the king of England or the English government, were given Irish possessions as a reward. The penal laws later made it a crime for a Catholic to acquire or hold land. Thus the Irish land question virtually began with the entrance of Henry II. into Ireland. With the Irish owners deprived of their lands there was instituted the system of "landlordism" which has been a hindrance to Ireland's progress. The majority of those who owned the land did not live upon it, and usually the money received for rent was spent in a foreign country. The landlord owned only the land, the houses had to be built and all improvements had to be made by the tenant and at his own expense. The more a holding was improved, the more rent was demanded. The "middle men" who held lands under the owner, and sublet to tenants were the means of increasing the burdens of the peasantry. The commission under Lord Devon, in 1843, to investigate conditions in Ireland, revealed an alarming state of affairs and the famine of 1846-8 brought the Irish Land question to the notice of the whole civilized world, even many of the English statesmen who had censured Irish shiftlessness were astonished when they learned the nature of the land laws which gave power of eviction without any remuneration for improvements; and the wonder was that so much thrift and industry existed. In 1847 Lord Russel endeavored to have Parliament pass an act to protect the tenant against loss by eviction. This measure failed, and others accepted by Parliament later proved ineffectual. Two years after the terrible devastation by famine, the Tenant Right League was organized in Dublin, and its members began a systematic campaign to elect to Parliament members pledged to support measures for the relief of the tenants. The Land Acts of 1860, under the Palmerston ministry, may be said to have resulted from the agitation kept up by the Tenant Right League. Various other organizations for the betterment of the people of Ireland were established, and among them were "physical force" societies. In 1870, under the Gladstone ministry, three new laws were enacted; that a tenant could not be evicted if his rent were paid; that this non-payment must be for at least three years; and that if the tenant choose, he might sell his improvements. This purchase of improvement clause was a great advance in favor of tenants' rights. The Land League in various parts of the world, especially the United States, continued the agitation and brought the question of the wrongs of the Irish tenants before the whole world. The Ashbourne Act of 1885 provided for the purchase of the lands by the tenants and nearly \$25,000,000 was set aside for that purpose. Later a like amount was added. In 1891 the Balfour Law Purchase bill was passed and nearly \$150,000,000 was provided for its enactment. In 1896 this law was improved; but for various reasons all the laws enacted by Parliament proved ineffective only in so far as the bringing of the matter to the notice of fair-minded statesmen. (See LAND LEAGUE) The most radical and satisfactory "Land Purchase Bill" was enacted 14 Aug. 1903, whereby the tenant

IRISH LITERARY SOCIETY—IRITIS

may purchase and own land and the government will, under certain and fair conditions, be responsible for the payment. To George Wyndham, who as chief secretary for Ireland, prepared the bill, the credit is largely due for the passage of the act. (See **WYNDHAM, GEORGE**) Consult: Reports on the "Land Purchase" acts for relief of Ireland; Hansard's "Parliamentary Debates"; Guinell, 'The Breton Laws'; Maine, 'Lectures on the Early History of Institutions'; Fisher, 'History of Landholding in Ireland'; Richey, 'The Irish Land Law'; Godkin, 'The Land War in Ireland'; Richey, 'The Irish Landlord.'

Irish Literary Society, an organization established in 1892, in London. Its object is to promote the study of Irish literature, music, art, and history. Some of the leading Irish literary men and women of England and Ireland are active or honorary members, and strive in many ways to promote the work of the society. The society provides lecture courses on topics pertaining to literary Ireland, and it has a large library which may be used by any of its members. Some of the members are Justin McCarthy, W. B. Yeats, Rev. Stopford Brooke, Barry O'Brien, and several of the well known writers among the Irish women. There were (in 1903) about 625 members.

Irish (Gaelic) Literature. See **CELTIC LITERATURE**.

Irish Moss, an edible dulse or seaweed. See **CARRAGEEN**.

Irish Music has been celebrated from almost prehistoric times. Irish teachers of the art as early as the 7th century holding high rank as specialists in the faculties of continental and English colleges. While the bagpipe was the popular instrument of the common people, the harp was in great favor among the noble and educated classes, and their professional harpists were noted for their skill. The Irish scale originally consisting of five notes, gradually developed with the addition of a sixth and a seventh, until the Irish harp had a finely graduated scale of tones and semitones either in the key of C or G, extending through a compass of four octaves. A harp in the museum of Trinity College, Dublin, said to be that of Brian Boru, has 30 strings, and the Dallway harp, made in 1621, has 52 strings. The national temperament was so musically imbued that there were special songs and airs for different crafts and for almost every conceivable occasion. War marches were played by the pipers at the head of the clansmen marching to battle; spinning, weaving, smithy, plowing, boating, and sporting songs were in daily use, and there were even milking songs, slow and plaintive airs which had the effect of soothing the cows and induced them to submit gently to the milking operation. In Irish literature, native music is frequently classed under three different styles, known as mirth, sorrow, and sleep music, comprising (1) lively, spirited pieces, as jigs, reels, hornpipes and other dance music; (2) solemn and slow pieces, as laments or dirges, commonly called *canticles* or *keens*, and sung on the occasion of a death; (3) plaintive and soothing airs, such as nurse tunes, cradle songs, lullabies, etc. In the numerous collections of these airs, about 2,000 different melodies are preserved, some of the

most popular being 'Savourneen Dheelish,' 'Eileen Aroon' (popularly known by the Scotch appropriation 'Robin Adair'), 'The Coolin,' 'Garryowen,' 'Langolee,' 'Molly Asthore' and 'Patrick's Day.' With the universal spread of music after the 17th century, Irish music as a national feature became merged in the general history of the art. Turlogh Carolan, Carroll O'Daly, Reilly and the Conallons were among the chief of Ireland's ancient harpists and musicians. In modern times Ireland's musical productivity is represented by Michael William Balfe, William Vincent Wallace, Sir Charles Villiers Stanford, and others. Consult: Graves and Stanford, 'Songs of Old Ireland and Irish Songs and Ballads' (1882-92); id., 'Songs of Erin'; Graves and Wood, 'Irish Folk Song'; Graves, 'Songs of Irish Wit and Humor'; and collections of Bunting, Joyce, Moore and Petrie.

Irish Presbyterian Church, formerly called the Synod of Ulster. Its members are mostly descended from the Scotch Presbyterians, who migrated to Ireland by invitation of James I., between 1609 and 1612, to colonize Ulster.

Irish Sea, the body of water between England and Ireland. It is connected with the Atlantic Ocean on the north by the North Channel, and on the south by Saint George's Channel. The north shore of Wales and the southwest shore of Scotland are washed by this sea. It is almost circular in form, about 140 miles north and south, and the same east and west. The largest arms of the sea are on the west shore. The Morecambe Bay on the coast of England, and several large fiords. Dublin and Dundalk bays are the most important on the west coast. The only large islands are the Isle of Man in the north, about midway between England and Ireland, and Anglesey off the northwest coast and a part of Wales.

Irish Terrier, a rough-coated, strongly built terrier, resembling the Welsh and Scotch terriers. See **Dog**.

Irish Texts Society, an organization established in London. Its object is to promote the study of Irish literature,—that is, of literature in the Irish text. They foster societies and issue publications to aid the work. In 1900 they published their third volume, which contained the poems of Egan O'Rahilly. In 1901 their annual volume contained Keating's 'History of Ireland,' edited by David Comyn. The volume of 1903 contains an 'Irish-English Dictionary.'

Iritis, i-rī'tis, inflammation of the iris, the colored curtain that shows the pupil in its centre. This disease follows several types, depending on the kind and virulence of the causative agent. In the serous form there is an exudation of blood-serum into the space in front of the iris, and more or less fibrinous matter that tends to glue the parts together. Pain shoots through the whole eyeball, and vision is dimmed by the turbid fluid. Persistent adhesions to the lens are formed, causing a permanent distortion of the shape of the pupil. Another form is the plastic, in which the pupil is actually occluded by the fibrinous deposits. Rheumatism and syphilis are the two most frequent causes of the malady, but many constitutional diseases—as gout, diabetes, anæmias, and menstrual disorders—may be factors in causing the disturbance, and it may also be secondary to diseases

IRKUTSK — IRON

in other parts of the eye, or even in the other eye, as in sympathetic ophthalmia. The treatment consists of dilating the pupil by dropping solutions of some drug, as atropine, into the conjunctival sac, treating the constitutional disease at the seat of the malady, and in relieving the pain by hot fomentations, blood letting, and the administration of drugs that are sedative. Syphilitic iritis is a lesion of the third stage of syphilis (q.v.), where tiny spots called gummata grow in the substance of the iris.

Irkutsk, Ir'kootsk, a provincial government of Russia, in eastern Siberia, separated from China by the Sayan Mountains. It has an area of 287,061 square miles. The country is generally mountainous, but produces rye, barley, oats and vegetables. The most important rivers are the Angara, Lena and its tributary the Vitim. Gold, iron, and salt figure foremost among the mineral products. Agriculture, cattle-breeding, and the transport of goods to and from China are the chief occupations of the people. Pop. 501,237 (one third exiles and forced colonists). The capital city, Irkutsk, on the Angara, is the residence of the governor-general of eastern Siberia and the seat of a bishop.

Iron, a common and exceedingly useful metallic element, which has been known and used in the arts for many centuries. It occurs in nature in the metallic form, both in meteorites and in certain lavas and volcanic rocks; but the commercial supply is obtained by the reduction of the oxids (or other ores) of the metal, by strongly heating them in a blast furnace with carbon. Iron is grayish in color, with a marked lustre. It crystallizes in the isometric system, usually in the form of cubes or octahedra. The melting point of iron varies to a considerable extent, according to the impurities with which the metal is associated, and also, apparently, according to the physical condition of the iron itself. Pictet gives it as about 2900° F. for iron that is sensibly pure. The specific gravity of the metal also varies to a considerable extent, the determinations ranging from 6.95 to 8.2. The specific gravity of pure iron, at 60° F., may be taken to be 7.85. The specific heat of the metal is about 0.112 at ordinary temperatures, and its coefficient of expansion (on the Fahrenheit scale) is about 0.0000068. Taking the electrical conductivity of mercury (at 32° F.) as unity, the conductivity of iron is about 9.68 at 32° F., and 6.19 at 212° F. Iron is the most magnetic substance known. Soft, pure iron is capable of being magnetized very highly when surrounded by a solenoid of wire that is conveying an electrical current; but its magnetization persists only while the electric current is flowing, falling off, upon the cessation of the current, to a value that is practically negligible. It is upon this property of temporary magnetization that the action of the telephone, the telegraph, and many other useful electrical inventions depends. (See MAGNETISM; and for a full discussion of the phenomena of magnetization, consult Ewing, 'Magnetic Induction in Iron and Other Metals.') Hardened steel, when magnetized by the action of the electric current (or otherwise), retains a large proportion of its magnetism permanently. Iron becomes non-magnetic at a red heat, but regains its magnetic properties upon cooling again. Wrought iron, when pure, is malleable to a certain extent at

all temperatures; but it yields to the hammer with special readiness when heated to whiteness, and it may then be forged and welded without difficulty. The presence of any considerable proportion of sulphur or phosphorus makes the metal "short," or brittle. When phosphorus is present in too great a proportion, the iron is brittle in the cold (that is, "cold-short"); while if sulphur is present in excess it is brittle when hot (that is, it is "hot-short").

Chemically, iron is a dyad. It has the symbol Fe (from "ferrum," the Latin name for the metal), and an atomic weight of 56 if O=16, or 55.6 if H=1. It forms two basic oxids, (1) ferrous oxid, FeO , which gives rise to a series of salts known as "ferrous" salts, and (2) ferric oxid (or ferric sesquioxid), Fe_2O_3 , which gives rise to a corresponding series of "ferric" salts. A third oxid, having the formula Fe_3O_4 , is also known, which is magnetic, and occurs in nature, either amorphous or crystallized in octahedra, as the mineral "lodestone." This oxid is black in color, and is known as the black oxid, magnetic oxid, or ferroso-ferric oxid. It may be prepared, artificially, by oxidizing iron at a high temperature, either in air or in steam, or by heating carbonate of iron to 650° F., in a current of carbon dioxide. It is not readily attacked by acids or other chemical agents, and for this reason a coating of it is often formed on articles of iron to protect them from further oxidation. The Russian iron that is used for stove-pipes is coated in this way, by a secret process. When in mass, iron does not readily decompose water at ordinary temperatures, though it does so at high temperatures. Finely divided iron decomposes water at 212° F., and at lower temperatures according to some authorities. When in a sufficiently fine state of subdivision, iron will burn in the air or in oxygen, with the formation of a mixture of Fe_2O_3 and Fe_3O_4 . Iron forms alloys with many metals, and combines directly with chlorine, bromine, iodine, fluorine, sulphur, carbon, boron, silicon, phosphorus, and arsenic. Melted iron dissolves carbon to some extent, and when the molten mass is cooled the carbon is largely deposited in the graphitic form, although a part of it remains in the iron, combined with it in the form of a carbide; and it is believed that the presence of varying quantities of such carbides has much to do with the physical qualities of iron and steel. When melted iron that is saturated with carbon is allowed to cool under great pressure, the carbon is partly deposited in the form of minute crystals of diamond (q.v.); but the manufacture of the diamond by this method has not yet been made commercially practicable.

Ferrous Compounds.—Ferrous oxid, FeO , has not yet been prepared in a state of absolute purity, but it may be obtained approximately pure by reducing ferric oxid, Fe_2O_3 , by heating it to 600° F. in a stream of pure hydrogen. It is black in color, and absorbs oxygen with great readiness, passing into the higher oxids. Ferrous sulphate, otherwise known as protosulphate of iron, green vitriol, or copperas, is prepared by dissolving metallic iron in sulphuric acid, and crystallizing by evaporation. It has the formula $\text{FeSO}_4 + 7\text{H}_2\text{O}$, and is greenish in color. It is soluble in water, but the solution oxidizes readily, the salt becoming converted into ferric sulphate, $\text{Fe}_2(\text{SO}_4)_3$. Ferrous sulphate is largely used in the manufacture of certain black dyes,

IRON AGE—IRON AND STEEL INDUSTRY IN AMERICA

in the preparation of writing ink, and, to a certain extent, in photography. The ferrous oxalate developer, made by mixing a solution of ferrous sulphate with one of oxalate of potassium, was formerly in great favor, but has now fallen into comparative disuse, owing to the discovery of other developers that are more active and more convenient to handle. Ferrous chloride, FeCl_2 , may be prepared by heating excess of iron wire or iron filings in chlorine, or by passing dry hydrochloric acid gas over hot metallic iron. It crystallizes in white, lustrous, six-sided forms, and is volatile at a yellow heat. In air it oxidizes readily to a mixture of ferric oxide and ferric chloride. Ferrous carbonate, FeCO_3 , is an insoluble compound, occurring in nature as "spathose iron ore," and constituting a valuable ore of iron. Ferrous sulphide, FeS , is a black or grayish-black body, which may be prepared by melting sulphur and iron together in the proportion of 56 parts (by weight) of iron to 32 of sulphur. It is insoluble in water, but dissolves readily in dilute acids, with copious liberation of sulphuretted hydrogen gas. It is therefore greatly used in chemical laboratories, where this gas is extensively used for the separation of the metals. (See CHEMICAL ANALYSIS.)

Ferric Compounds.—Ferric oxide, Fe_2O_3 , occurs native as hematite (q.v.), and it may be prepared artificially by heating ferrous sulphate to redness. Ferric hydrate, $\text{Fe}(\text{OH})_3$, is precipitated as a brownish-red powder when ammonia or caustic potash is added to the solution of a ferric salt. Ferric sulphate and ferric chloride are prepared by dissolving this hydrate in sulphuric and hydrochloric acids, respectively. In general, a ferrous salt, when in solution, is converted into the corresponding ferric salt by the action of oxidizing agents; and the ferric salts, conversely, are reduced to ferrous salts by the action of certain reducing agents. Ferrous salts give a white precipitate with caustic alkalies, and, with potassium ferrocyanide, a light-blue precipitate which quickly turns black. Ferric salts give a reddish-brown precipitate with caustic alkalies, and a deep blue precipitate with potassium ferrocyanide. Iron is sometimes called "ferrosom" when it is present in a ferrous salt, and "ferricum" when present in a ferric salt. See IRON AND STEEL INDUSTRY IN AMERICA.

Iron Age, (1) in mythology, the last of the four great ages of the world, supposed to be characterized by abounding oppression, vice, and misery. (2) In archaeology, an age, the third in succession, in which weapons and many other implements began to be made of iron, stone having been used for these purposes in the first, and bronze in the second.

Iron and Steel Industry in America. Both the Assyrians and the Egyptians used implements of iron many centuries before the Christian Era. Iron and furnaces in which it was made are mentioned in the Pentateuch. The Greeks obtained their iron from the Chalybes, a nation on the south coast of the Black Sea. The Romans procured their iron from there, and also from Spain, Elba, and Styria. The iron mines of Elba, which to the present day yield a large amount of ore, were worked by the Etruscans, and the method employed by them for extracting the iron from its ores was

probably very similar to that now known as the Catalan forge process. Probably the aboriginal inhabitants of North America were unacquainted with the use of iron in any of its forms.

The iron of commerce is classified under three groups. These are "wrought iron," "steel," and "cast" or "pig iron." When a lump of pure and easily reducible iron ore is heated on a bed of ignited charcoal in a smelting-fire or forge it is readily reduced to a lump of metallic iron similar in shape to the mass of ore treated. If the lump be sufficiently large, one end may be hammered and drawn out into a bar or rod, while the other end remains in the fire as a mass of reduced or partly reduced ore. Such an operation represents the essential features of the primitive methods of iron smelting practised in the early colonial days of this country; the product thus obtained is known as wrought or malleable iron, whether it is made in the rude manner described or by the improved bloomeries which later replaced the rude old forge. From the bloomery, producing its soft malleable bar or bloom, the blast-furnace was gradually evolved, new metallurgical reactions were effected, and the product was obtained in a fluid condition, in which it could be run into simple sand receptacles, forming pig iron, or into specially constructed molds to produce castings for practical use. The metal thus obtained was hard, brittle, and possessed physical characteristics distinct from malleable iron. Since by the use of improved methods it became possible to obtain the product of the blast-furnace readily and with vastly greater economy, pig iron soon became, as it is at present, what the Germans call raw iron (*Roheisen*), from which practically every other variety of finished iron or steel is obtained. The ton of pig iron is therefore taken as the rough standard by which the world's production of iron is measured.

In the colonial period the British government systematically discouraged all efforts of the colonists to produce iron, in order to avoid competition with home industries. There were forges or bloomeries in nearly all the colonies from the times of earliest settlement, and as unlimited supplies of fuel were always at hand in the vast forests it was only necessary to find ore and obtain persons who could construct forges. The iron required for structural purposes, such as bars, straps, nails, sheets, etc., was obtained in the early days either by hammering the bloom from the forge or by shaping with rolls propelled by water-power. In fact, before the invention of the puddling process in England by Cort, in 1784, a large proportion of all forms of wrought iron were derived in this manner. The old so-called "Walloon" process of refining pig iron into the malleable or wrought form or into a crude mild steel was introduced into the colonies at an early date in their history. By the puddling process malleable iron is not directly produced from the ore, as in the older methods of manufacture, but indirectly from pig iron. The introduction of the puddling process was second in importance to no other invention in the history of the iron industry of this country. After the Revolution the iron industry developed steadily but slowly, probably owing to the fact that, as in colonial days, much, if not most, of the iron used along the seaboard was imported. No statistics of the production of iron were collected before the year 1810. The produc-

IRON AND STEEL INDUSTRY IN AMERICA

tion of pig and cast iron in that year was 53,908 tons; wrought and malleable iron of all kinds, 27,105 tons; having a total value of \$6,081,374, of which amount Pennsylvania produced \$2,473,748. The product of the steel furnaces of Massachusetts, Rhode Island, New Jersey, Pennsylvania, Virginia and South Carolina in 1810 was 917 tons, valued at \$144,736; of the whole number of steel furnaces Pennsylvania contained five, producing 531 tons, valued at \$81,147. An analysis of these figures gives us some idea of the state of the industry at the beginning of the century. The product of the blast-furnaces — pig, or, as it was at that time termed, cast iron — was run directly into small castings then in demand for commercial purposes; the malleable iron was probably all derived directly from the ore in forges or bloomeries, whence it was taken to the rolling or slitting mills to be made into rods, bars, plates, nails, etc. The steel made at this period in the United States was probably all produced by the cementation or blister process, and was all of the grade now known as high-carbon or tool steel. Although Huntsman's improvement of this process, by which the steel bars thus made were fused in crucibles and subsequently cast into ingots, had been in operation in Sheffield, England, a number of years prior to 1810, it is doubtful if his invention had been adopted in the United States at this early date. In the census of 1820 the quantities of iron made are not given; their value, however, is stated as follows: Pig or cast iron, \$2,230,275; wrought iron, \$4,640,669; total, \$6,870,944. The 1830 census gave: Pig iron and castings, \$4,757,403; wrought iron, \$16,737,251; total, \$21,494,654. The production of iron steadily increased upon much the same lines as before and in 1840, 804 blast-furnaces produced only 286,903 tons of iron, and 795 bloomeries, forges, and rolling-mills only 197,233 tons of malleable or bar iron. For the first time in the history of the industry the production of cast or pig iron exceeded that from the bloomeries and forges. No figures are published for the value of the product in 1840, but if we assume the ton of pig iron to have cost \$30, and the ton of hammered bar iron \$90, we obtain \$8,607,090, or nearly double the value of pig and cast iron produced in 1830. The total value of the bar iron at this estimate would be \$17,750,970.

The high cost of manufacturing charcoal, and its enormous consumption in the furnace per ton of iron produced, were serious obstacles to the growth of the industry, even where a good supply of ore was well assured. As early as 1835 the adaptation of anthracite to the manufacture of iron began to attract attention, and Franklin Institute offered a gold medal "to the person who shall manufacture in the United States the greatest quantity of iron from ore during the year, using no other fuel than anthracite coal, the quantity to be not less than 20 tons." The medal was never awarded, but there is abundant evidence that from 1830 to 1840 a number of attempts to use mineral fuel in smelting iron ores were made. The first practically successful attempt to produce pig iron by the use of anthracite was made by David Thomas at Catasauqua, Pa. The furnace which he erected there for this purpose was blown in on 3 July 1840. It was equipped with a "hot blast" operated by water-power, and thus inaugurated in the

United States, two of the greatest innovations in blast-furnace practice. This furnace, producing from the start 50 tons of iron per week, continued in profitable operation until the year 1879, when it was dismantled. The early forms of hot-blast apparatus consisted of nests of iron pipes heated externally by separate fires, the object being to pass the air from the blowing- or blast-engine through these pipes, thereby greatly augmenting its temperature, and to decrease the consumption of fuel per ton of ore smelted. The hot blast was patented in 1828 by James B. Neilson of Glasgow, and its use is perhaps the most important improvement ever made in blast-furnace practice, for without it the present large and cheap production of pig-iron would have been impossible. Notwithstanding that the success in smelting iron in blast-furnaces with anthracite had been practically demonstrated in 1840, the general use of this fuel appears to have grown slowly; it was 10 or more years before the use of coal (either anthracite, coke, or a mixture of the two) became general. In 1846 the first furnace constructed with the intention of using raw bituminous coal as fuel was successfully placed in operation at Lowell, Mahoning County, Ohio. Although coke had been in general use in England for a number of years, it was not until 1837 that it was successfully used in the United States in the blast-furnace at Lonaconing, Allegany County, Md. The manufacture of Connellsville coke was commenced in 1841, but, according to Weeks, it was not until a number of years later, when railroad transportation had become more fully developed, that its value as a furnace fuel became thoroughly demonstrated. The period between the years 1840 and 1850 was a most eventful one in the history of the American iron industry. The introduction of the improvements in smelting already indicated, together with the use of steam-power for propelling the blast and in performing other varieties of work about the furnaces, its replacement of water-power in operating rolling-mills and hammers, in mining coal and ore, and the rapid growth of the railroads, produced a stimulating effect probably never before experienced in a similar degree by any American industry. The railroads contributed largely to the development of the iron industry in two ways: directly, by rendering transportation comparatively cheap, thereby enlarging the iron market and increasing the demand; and indirectly, by creating in their construction a new and unprecedentedly large consumption of iron. As the production of iron increased in later years, the older iron-ore deposits became exhausted, or were proved inferior to the newly discovered ore-beds of the Lake Superior region. The problem of suitably locating a modern blast-furnace producing from 9,000 to 10,000 tons of pig iron per month became a serious one, and its solution has had the effect of moving the geographical centre of the iron industry west of the Alleghany Mountains, nearer a new and larger ore supply, yet handy to the coke of Connellsville. In 1850 there were produced in the United States 563,755 tons of pig iron by 377 establishments, and wrought iron to the value of \$22,629,271 in 552 establishments.

The evolution of iron and steel plate making, particularly boiler-plates, forms an interesting chapter in the growth of our great industry.

IRON AND STEEL INDUSTRY IN AMERICA

About 1815, when steam began to be used, Dr. Charles Lukens remodeled his mill to produce thicker plate. The bloom was reheated at the forge and hammered thin, usually about one and a half inches. It then went to the rolling-mill, where it was laid on a bed of coal in what was called a grate-furnace. After heating, it was rolled into plates one quarter and three sixteenths of an inch thick and sent to the boiler maker. But soon the mill began shearing into regular commercial sizes: 48 and 49 by 26 by one quarter or three sixteenths; or, if large enough, it was sheared into plates 68 and 69 by 26, and the scrap was cut into nails. But when the reverberatory furnace was introduced, the scrap was arranged into piles of such size as was necessary to produce the required plate, heated to a welding heat, and rolled in the mill. This state of things continued until the introduction of the puddling furnace. The most important advances made in the years between 1850 and 1860 were the invention of the "three-high" roll-train; the introduction of mills for rolling beams, by Cooper & Hewitt, at Trenton, N. J.; and the invention in 1848 of the "universal mill," by Daelin, a German engineer, which found its way to America 12 years later. In the manufacture of the finer qualities of steel, no progress was made up to 1860. According to the census of 1860, 97 establishments in the United States produced 51,290 tons of blooms, valued at \$2,623,178; 286 establishments produced 987,559 tons of pig iron, worth \$20,870,120; 256 establishments produced 513,213 tons of rolled iron, worth \$31,888,705; 13 establishments produced 11,838 tons of steel (probably of cheap grades), worth \$1,778,240.

During the Civil War the resources of the iron industry in the Northern States were taxed to their utmost. The industry in the South, strained at an early day beyond its feeble capacity, soon broke down, and most of the requirements of the Confederate armies were supplied from abroad. In the train of dire disaster wrought by the Civil War some good to the iron industry may be found; for not only did iron ships make their appearance in the navy, but the use of iron plates had its inception. As early as 1859 the French had built the frigate Gloire, armored with iron plates five inches in thickness, and in 1861 the British constructed the frigate Warrior, which was protected by solid iron plates four and a half inches thick. As regards armor, either of these vessels was much better protected than any of our monitors constructed during the Civil War, for the first monitor was protected by six to eight thicknesses of one-inch iron plates bolted one on the other with overlapping joints, and later vessels were probably protected in much the same way by armor made up of a greater number of similar one-inch plates.

In 1855 and 1856, Henry Bessemer, of London, had obtained patents for a process of converting molten pig iron into steel by forcing small jets of cold air through the molten iron; but his invention was not successful until modified by Robert F. Musket, who added to the molten steel, after the blast had been stopped, a sufficient quantity of spiegeleisen (an alloy of iron and manganese) to neutralize the oxide of iron caused by blowing and to give the steel the proper degree of hardness and fluidity.

Neither Bessemer nor his American rival, William Kelly, of Pittsburg, who secured a patent but did not utilize it, accomplished anything in America until 1866, when their interests were combined with Musket's and the first plant to produce the steel as a commercial article was put in successful operation by the Pennsylvania Steel Company at Steelton, near Harrisburg, Pa., June 1867. The first steel rails rolled in the United States in the way of regular business were rolled by the Cambria Iron Company, Johnstown, Pa., August 1867, from ingots made by the Pennsylvania Steel Company. The production of Bessemer steel in the year 1867 was 3,000 tons, the industry continuing to grow with rapid strides. In 1890, 4,131,535 tons were produced, in 1900 7,532,028 tons, and in 1902 9,138,363 tons. Of these amounts 2,550 tons were made into rails in 1867, 1,853,862 in 1890, 2,250,457 in 1900, and 2,935,392 tons in 1902. The importance of the invention of the Bessemer process to the world in general and the United States in particular cannot be overestimated, since it has reached a development with us greater than in any other country in the world. In 1901 the total amount of all varieties of steel made in the United States was 44 per cent of the entire world's product. The rapid and enormous development of the Bessemer-steel industry in the United States is attributable chiefly to the great extension of our railroads. Bessemer steel is also used for steel bars, merchant steel and for tin plates. The basic Bessemer or Thomas process though used in Germany to produce 4,888,054 tons in 1902, has not gained a foothold in this country.

The open-hearth steel process was first used in 1856, when the Siemens Brothers of London perfected what is now generally known as the Siemens regenerative gas-furnace, without which no open-hearth steel can be made. In 1864, Messrs. Emile and Pierre Martin, of the Sireuil works in France, erected, with the assistance of Dr. Siemens, one of the regenerative gas-furnaces to convert steel in an open-hearth or reverberatory furnace of their own construction. This scheme was a success from the start, and by a subsequent consolidation of the Siemens and Martin inventions a steel-making apparatus was devised, known as the Siemens-Martin or open-hearth process. This process was introduced into America in 1868 by F. J. Slade for Cooper, Hewitt & Company, at the works of the New Jersey Steel and Iron Company, at Trenton, N. J. In 1870 the production of open-hearth steel in the United States was 1,500 tons, and in 1890 574,820 tons, the industry showing a rapid development during the intervening 20 years. Great Britain was long the largest producer of open-hearth steel in the world, and in this branch of the iron industry the United States was somewhat behind its great rival, until 1900. In 1890 Great Britain produced 1,564,200 tons, as against 574,820 tons in the United States; in 1899 Great Britain produced 3,030,251 tons and the United States a little more than 2,000,000 tons; but in 1900 the figures are 3,398,135 tons for the United States (following James M. Swank, 'Iron and Steel at the Close of the 19th Century,' 1901; the census figures, always incomplete, are 3,044,356) and 3,156,050 for Great Britain. This growth is all the more striking when it is known that in 1895 the writer of this article hopefully

IRON AND STEEL INDUSTRY IN AMERICA

prophesied that the production might reach in that year 1,000,000 tons. Five years later it had passed the 3,000,000-ton mark. The so-called "basic" open-hearth process, although in successful operation in Europe for a number of years, was not introduced into the United States until 1888, when a number of such furnaces were constructed at the works of Carnegie, Phipps & Company, at Homestead, near Pittsburgh, Pa. Without going into technicalities, the basic open-hearth process may be briefly defined as an ordinary open-hearth plant whose furnace lining is made of a basic material, such as dolomitic limestone or the mineral magnesite. When pig iron containing a sufficiently great quantity of phosphorus to render it unfit for conversion into steel by any other method is melted in such a furnace, the basic lining, together with a basic flux which is added, removes the objectionable phosphorus and renders (other conditions being normal), the resulting steel equal to that prepared in the open-hearth furnace in the old and usual manner. The purposes for which open-hearth steel is ordinarily adapted are quite different from those for which the Bessemer steel is most suitable; but the converse of this fact, however, is not true, since open-hearth steel may be and frequently is used to an equal, if not greater, advantage wherever Bessemer steel is employed. In this country, at least, all high-grade structural material, such as boiler and ship plate, bridge and building members, high-grade castings, etc., is almost invariably of open-hearth steel, which is generally considered, and doubtless is, more uniform in quality than soft steel made by the Bessemer method.

One of the most curious phases in the history of the American iron industry is the fact that although the United States at one time consumed nearly 60 per cent of the world's entire production of tinned plates, with the exception of a few sporadic attempts in 1873 and 1875, no tin or terne plates were made in the United States until 1891. Great Britain furnished virtually all the tin-plate used in the United States during the 20 years ending 1890. No better evidence of the success of our domestic tin-plate industry could be afforded than the fact that our imports have steadily decreased since 1889, those for 1890 being 29,435 tons, for 1894 215,068 tons, and for 1900 only 60,386 tons. The American production amounted to 999 tons in six months of 1891; to 6,092 tons in 1892; 44,503 tons in 1893; over 100,000 tons in 1895, and in 1900 to 302,065 tons. The census of 1900 reports 57 establishments manufacturing tin and terne-plate; gives their capital as \$6,650,047, its wage-earners as averaging 3,671, and their wages as \$1,889,917; and estimates the cost of materials at \$26,728,150, and the value of the product as \$31,892,011. In 1890 the industry was prac-

tically non-existent and was not reported in the census of that year.

If the history of the development of the American blast-furnace practice were written it would form a large book of itself. In 1870 most of the blast-furnaces in operation were still very primitive, and although no statistics for that year are given, it is probable that the best of them did not produce as an average over 50 tons of pig iron per day, whereas in 1902 the production of 300 tons per day was a common occurrence, and some furnaces regularly produced over 500 tons daily. The table at the bottom of the page taken from the United States census reports, exhibits the production of pig iron from 1870 to 1900.

These figures show the rapid fall in the number of establishments, resulting from the movement of concentration nowhere so strikingly shown as in the steel and iron industry. The capital invested has increased 150 per cent approximately in 30 years, the production nearly 700 per cent and the value of the product almost 200 per cent. During the 20 years between 1870 and 1890 production in the Middle States had nearly quadrupled, in the Western States increased nearly 5 times, and in the Southern States nearly 10 times. In 1890 the American product passed the record figures of the British furnaces, made in 1882. Between 1890 and 1895 the American trade suffered considerably and fell below the British in its total product; then it again advanced and is now 100 per cent greater than that of Great Britain.

The wonderful growth of the world's iron industry within 50 years is shown by the following tables, in metric tons (2,204 pounds).

COUNTRY	1854	Per cent	1902	Per cent
United States	750,000	12.5	18,003,448	40.7
Great Britain	3,000,000	59.0	8,653,970	19.5
Germany	400,000	6.6	8,402,660	19.0
France	750,000	12.5	2,427,427	5.5
Russia	200,000	3.3	2,566,000	5.8
Austria-Hungary	250,000	4.3	1,335,000	3.0
Other countries	650,000	10.8	2,869,480	6.5
Totals.....	6,000,000	100.0	44,257,991	100.0

Even more striking is the increase in steel output in the last 35 years, as shown below:

COUNTRY	1867	Per cent	1902	Per cent
United States	19,963	4.1	15,186,406	44.0
Great Britain	235,000	47.8	5,102,420	14.8
Germany	122,591	26.0	7,780,682	22.5
France	47,597	9.7	1,635,300	4.8
Russia	6,271	1.3	1,730,250	5.0
Austria-Hungary...	15,000	3.1	1,143,900	3.3

IRON CITY—IRON IN MEDICINE

The total iron and steel exports and imports of the United States for the years 1890, 1900, and 1902 are shown below, the totals being long tons (2240 pounds).

YEAR	Exports	Imports	Excess
1890.....	45,687	603,749	Imp. 558,062
1900.....	1,154,284	209,955	Exp. 944,329
1902.....	370,805	1,212,839	Imp. 842,034

A sketch of the American iron industry would be incomplete without some reference to the introduction of the manufacture of armor-plate into the United States. This class of material not only has a peculiar and limited demand, but its manufacture requires the highest degree of metallurgical and mechanical skill, together with an exceptionally expensive plant. When the reconstruction of the United States navy was begun, some 20 years ago, we had absolutely no facilities for making the simplest kind of armor-plate, although we had some of the largest steel-works in the world. One of the first of the new armored vessels completed (the monitor *Miantonomoh*) was protected by "compound" plates imported from England. All the large forgings for the guns and shafts of the earlier ships were likewise imported. Owing to the policy of Congress, the Bethlehem Iron Company, and Carnegie, Phipps & Company, of Pittsburgh, were induced to erect expensive plants necessary for making not only the heavy gun-forgings required, but also for all the different grades and thicknesses of armor-plate. In 1891 these firms began to supply armor for the ships in course of construction, although at first their output of finished armor was extremely slow. The delays have now been slowly overcome, and at the present time there is little doubt that these great steel-works will be able to supply the armor as fast as new ships are constructed. How successful these works have been in furnishing our government with the best grades of armor-plate could have no better illustration than the fact that the Bethlehem Iron Company soon began supplying foreign governments with armor for their ships. The only two important iron and steel commodities which the iron industry of the United States did not supply in 1890 (tin-plate and armor-plate) are at present being made in large quantities, and the census for 1900 reports during the year 1900 15,302 tons of armor plate all produced in Pennsylvania, and valued at \$7,526,479. Vast improvement has been made in the machinery necessary to manipulate iron and steel. The Bethlehem Iron Company has a hammer of 125 tons' capacity, built by John Fritz and put into successful operation in 1891. But armor-plate is no longer rolled nor forged by hammers, but manufactured with huge hydraulic presses, some with an energy of 15,000 tons. George Fritz is the inventor of what is known as the "automatic tables," which with John Fritz's roll train enables the manufacturer to successfully handle almost any weight of ingot. I well remember when a 500-pound mass of iron was thought to be so heavy that the whole neighborhood gathered in to see it rolled. The necessity of handling such very heavy weights as could be made from ingots cast in large masses brought into play the invention of hy-

draulic machinery, so that we now have pumps to produce any required pressure in a series of pipes which deliver the water to the hydraulic engines in any part of the works. By simply turning a valve now a boy will pick up a heavy ingot (say of 10,000-pound weight) with his hydraulic crane and deliver it anywhere within reach of the crane. If on a car, it may then be taken by a small locomotive to the rolling-mill, where another crane picks it up and puts it into the furnace, and, after heating to the required degree, takes it out and delivers it to the machinery at the rolls; then the automatic tables push it back and forth through the rolls until it is reduced to the required dimensions. The same tables now take it to the shears, which are also operated by hydraulic power, and the plate, sometimes two inches thick, is sheared ready for shipment. All this is done with more ease than was possible a few years ago. Within the last few years electricity has been brought into play to do some of the heavy work.

CHARLES HUSTON.

*Revised by S. SANFORD,
'Engineering and Mining Journal,' New York.*

Iron City, a name given to Pittsburg, Pa., owing to its extensive iron industries. "Smoky City" is another name frequently applied to Pittsburg because of the large number of rolling-mills, furnaces, and foundries in which bituminous coal is used.

Iron Cross, a Prussian order, instituted by Frederick William III. in 1813, and conferred for distinguished services in war. The decoration consists of a Maltese cross of iron, edged with silver. The order was revived by William I. in 1870, on the eve of the great war with France. The grand cross, of double size, is presented exclusively for the gaining of a decisive battle.

Iron in Medicine. Iron was in use in medicine by the Chinese as early as 2700 B.C., and was employed in the treatment of anaemia much as it is administered to-day. In its native form, as iron, it is devoid of action, but when reduced to a salt, or oxide, capable of dissociation, it becomes active. Iron differs from many of the other heavy metals in that it is an active ingredient of the tissues, and is probably essential to the life of many if not all forms of living things. In the human blood it is an absolutely essential constituent, and its importance is great for all of the tissues of the body. In a number of the animals that lack red blood-corpuscles iron is not found abundantly in the blood, but is nevertheless present in large amounts in all parts of the body, and is perhaps just as essential for the chemical processes of nutrition as in higher vertebrates. It is well known that the presence of iron is necessary for the active processes of photosynthesis in plants, and that in its absence the higher plants are unable to develop chlorophyll, although chlorophyll itself does not contain iron in the form of haemoglobin. It is of interest, however, to note that Nencki, a Russian biologist, has shown that reduction compounds of haemoglobin and of chlorophyll are very closely allied, and he propounds the interesting speculation that probably the same iron compound was present in the living matter before a differentiation of animal and plant was made, and that as plants and animals developed along divergent lines of struc-

IRON MASK—IRON MOUNTAIN

ture the iron compounds became somewhat separated in their chemical character.

Iron combinations in medicine are usually divided into two classes, inorganic and organic. In the former the iron is dissociated in solution, and is usually acted upon by the hydrochloric acid of the gastric juice and converted into soluble chlorides, in which form it probably enters into the tissues. In the organic iron it is probable that the same conversion takes place, although there is much controversy regarding the method of its absorption; but this is true of all iron. The iron is usually taken up in the stomach and intestines, the larger part of it being rejected, and it enters into the blood in the form of an albuminate which passes into the duodenum, some being absorbed by the epithelium, and more or less of it carried directly to the spleen and probably to the liver. In the spleen it seems to undergo some changes, and is taken up by the blood and thereafter deposited more particularly in the liver and in the bone-marrow. When there is deficiency of iron in the blood or other organs, the liver gives up its store and it is absorbed by the tissue that is most in need of it. While in the blood, iron is the great organ of oxidation. By means of the haemoglobin the oxygen of the air is taken up and distributed to the different parts of the body. This permits of the active chemical oxidative changes that take place throughout the entire body, which changes are of such vital importance in general metabolism, and without which the body suffers, degenerates and dies.

Iron is used particularly for diseases in which the blood is poor in that metal. This is particularly the case in anaemias of primary and secondary character. In primary anaemia or chlorosis (q.v.), iron is a distinct help, often curing the condition. In primary pernicious anaemia, which is a grave blood-disease, it is of secondary value. In all of the secondary anaemias, those that follow hemorrhage, the acute infectious diseases, such as scarlet fever, malaria, whooping-cough, measles, typhoid, pneumonia, etc., iron is of great service. It is particularly valuable following childbirth or any condition in which there has been a great loss of blood. It is also useful in conditions of scanty menstruation, in tuberculosis, and is one of the best general tonics in the realm of medicine. The effects of inorganic and iron solutions on the teeth should be borne in mind, although they are much exaggerated. Iron is apt to cause a certain amount of constipation, but this, by proper laxatives regularly taken, should be overcome.

Iron Mask, The Man with the, a famous personage who was kept a prisoner in two or three French prisons in the time of Louis XIV., and who excited a curiosity corresponding to the care with which his identity was concealed. His first prison was the castle of Pignerol, of which Saint-Mars was governor. In 1686 he was carried by Saint-Mars to the isles of St. Marguerite; and the same precautions were observed as upon his first journey. Saint-Mars having been appointed governor of the Bastile in 1698, carried the prisoner with him there, but still masked. An apartment had been prepared for him more convenient, and furnished with more care than those of the other unfortunate beings who inhabited this sad abode. He was not permitted to take off his mask even before

his physician. In other respects the greatest attention was shown him, and nothing which he requested was refused him. His education appeared to have been carefully attended to; and he amused his leisure by reading, and playing upon the guitar. This unknown person died 19 Nov. 1703, at 10 o'clock in the evening, without having undergone any severe sickness. He was buried the next day in the afternoon in the cemetery of the church of St. Paul. He was, it was said, about 60 years of age, although the register of burials for the church of St. Paul, in which he is mentioned under the name of Marchiali, makes him only about 45. It is said that orders were given to burn everything which had been employed in his service; that the walls of the chamber which he had occupied were rubbed down and whitewashed; and that the precautions were carried so far, that the tiles of his room were removed, in the fear that he might have displaced some of them to conceal a letter behind them. Conjecture exhausted itself to discover who this mysterious personage might be.

At the time of the destruction of the Bastile, in July 1789, there were not wanting curious persons, who sought, in the archives of this fortress, to discover some notices which might throw light upon this historical problem. But to no purpose. A widely-accepted conjecture was first thrown out in a letter written in 1770 by Baron D'Heiss to the 'Journal Encyclopédique.' According to this view the Man with the Iron Mask was Count Girolamo Magni, or Mattioli, first minister of the Duke of Mantua, who had betrayed the interests of Louis XIV. by failing to secure for him, as he had pledged himself to do, in consideration of a large bribe, possession from his master of the fortress of Casale. For this offense he was lured to the French frontier, secretly arrested, and imprisoned in the fortress of Pignerol in 1679. The secret was preserved so carefully, on the supposition that Mattioli was the prisoner, because his seizure and detention were flagrant violations of international law. In a more recent investigation by M. Jung, 'La Vérité sur le Masque de Fer' (1873), an attempt is made to identify the Mask with a gentleman of Lorraine, who was connected with an association for the assassination of Louis. Funck-Brentano in 1894 revived the view that Mattioli was the mysterious prisoner, and many now consider the controversy settled and this view established. Consult: Hopkins, 'The Man in the Iron Mask.'

Iron Mountain, Mich., city, county-seat of Dickinson County; on the Chicago, M. & St. P. and the Chicago N. W. R.R.'s; about 47 miles southwest of Marquette and 57 miles west by north of Escanaba. It was settled in 1879 and chartered in 1888. It is the commercial centre for a large mining section in Michigan and for a farming section in Wisconsin. Its chief manufactures are mining and agricultural implements, and its trade is principally in iron-ore and farm products. Pop. (1900) 9,242.

Iron Mountain, the southern spur of the St. Francois Mountains, a low range in the eastern part of Missouri. This mountain, which is really a hill or knob, is in St. Francois County, about 60 miles southwest from St. Genevieve, the nearest point on the Mississippi River. It is about 300 feet above the surrounding land and

IRON ORES

about 2,000 feet above the sea. It covers an area of 500 acres. It is famous for its remarkable mineral deposits, specular or hematite iron-ore, the purest iron ore in the United States. The average elevation above the land around is 550 feet, and the area it covers is about 500 acres. Large oak trees flourish on its slope, their roots embedded in soil composed largely of fragments of peroxide of iron. Excavations were begun in 1845. An artesian well has been sunk to the depth of 152 feet, with the result that the beds passed through from the surface were as follows: Iron ore mixed with clay, 16 feet; sandstone, 34 feet; magnesian limestone, $7\frac{1}{2}$ inches; gray sandstone, $7\frac{1}{2}$ inches; hard blue rock, 37 feet; pure iron ore 5 feet; porphyritic rock, 7 feet; iron ore 50 feet to the bottom. It would seem that nearly the whole mountain was a mass of magnetic iron ore. The adjacent valleys are underlaid with magnesian limestone in horizontal strata. Pilot Knob (q.v.), about six miles south of Iron Mountain, also contains an extensive deposit of iron ore; Shepherd Mountain, a short distance southwest of Pilot Knob, is the largest of the iron mountains in that immediate vicinity.

Iron Ores. Although iron is the most abundant of the useful metals, forming 5 per cent of the earth's crust, it is rarely found native—one famous native occurrence of it, however, being at Ovifik on the west coast of Greenland. The iron ores of chief commercial importance are hematite, magnetite, limonite, siderite and pyrite. Pure hematite contains 70 per cent iron; magnetite 72.4 per cent; limonite 59.89 per cent; siderite 48.27 per cent; pyrite 46.6 per cent. Iron ores, however, are practically never mined pure, but are mined in quantity averaging 10 per cent and over less iron than above stated, the principal impurities being silica, alumina, and lime.

Hematite, ferric oxide (Fe_2O_3), by far the most important iron ore, varies greatly in physical characteristics. Specular hematite is black, with a brilliant metallic lustre. Martite is a variety of hematite. Magnetite, a ferro-ferric oxide ($FeO.Fe_2O_3$), is black magnetic, and crystallizes in octahedra, but as mined it is usually massive or granular. Ilmenite, an oxide of iron and titanium, is not yet an ore of commercial importance. Franklinite, an oxide of iron, manganese, and zinc, found at Franklin, N. J., is used in making spiegeleisen, an alloy of iron and manganese after the zinc has been removed by roasting. Limonite or brown hematite, hydrated ferric oxide ($2Fe_2O_3 \cdot 3H_2O$), is brown or yellow in color and occurs in massive, earthy, or in botryoidal forms. Bog-ore is a variety of limonite. Goethite, differing from limonite in crystalline form and containing less water, is found in large quantities in Minnesota. Siderite, or spathic iron, ferrous carbonate ($FeCO_3$), is white to gray when pure, and crystallizes in rhombohedra. As mined, it varies much in appearance, owing to oxidation. Clay iron stone is siderite mingled with clay. Blackband ore is siderite mixed with more or less bituminous matter. Pyrites, ferric disulphide (FeS_2), often called "fool's gold," is used in great quantities to make sulphuric acid. The residue, known as "blue-billy," or pyrites clinker, is in some countries smelted in the blast-furnace as an iron ore.

In smelting an ore the silica, lime, and alu-

mina are removed as slag. Ores high in silica require more limestone in the furnace-charge for fluxing, that is, for combining with the silica. Some ores contain silica and lime in such proportions as to be self-fluxing. The higher the iron content of an ore, generally speaking, the greater the yield per ton of material put through the furnace, and the lower the cost per ton of the iron made.

A very hard ore must be broken into small lumps to give best results in the furnace. Hematites often smelt easier than magnetites. A fine granular ore makes trouble in smelting, and a certain proportion may be lost as dust, which clogs furnace-flues. The really injurious impurities most often found in iron ores are sulphur, phosphorus, and titanium. Sulphur can be largely removed by roasting the ore before smelting; phosphorus cannot, and all the phosphorus in the ore goes into the iron. For making steel by the Bessemer process an ore should contain less than 1-1,000 of its amount of iron; thus, to be classified as Bessemer, an ore containing 61 per cent iron should contain less than .061 per cent phosphorus. For making steel by the basic process, high phosphorus ores are used.

The present development of the world's iron mines is the outcome of many factors. Generally speaking, it is cheaper to bring the ore to the fuel than the fuel to the ore, hence, countries or districts that have great supplies of iron ore may be insignificant producers of pig-iron. Low-priced fuel has been the chief factor in determining the location of iron and steel industries, while the chief factors in the development of iron mines are the quality of the ore and the cost at which it can be put down at the furnace.

Iron-Ore Supplies of the World.—The iron industry in Asia is several thousand years old, but the annual output of iron ore is small. China has vast but little-developed deposits of limonite and hematite. Japan is very poor in iron ores. The iron industry of Australia is not of importance. The only ores exported from Africa are mined in Algeria, where the annual production has fallen to about 150,000 tons. Europe has famous ore fields. The ores of Elba and those of Styria were worked by the Romans. Certain Swedish mines have been worked almost continuously since 1300. The German output now comes chiefly from so-called minette beds of Lorraine and Luxemburg. The ore, a low-grade limonite high in phosphorus, is used in making steel by the basic process, and the present annual output is over 7,000,000 tons annually. The total ore supply left in the field is estimated at nearly 2,000,000,000 tons. The iron fields of Great Britain have passed their greatest productiveness. The principal districts are Cleveland in North Yorkshire, yielding clay ironstone containing about 30 per cent iron; Cumberland and Lancashire, yielding red hematite containing 50 to 60 per cent iron; and Lincolnshire, Leicestershire, and Northampton, yielding cheaply-mined low-grade hematite. The blackband ores of Scotland are of much less importance than formerly. The principal Spanish mines are in the Bilbao district in the province of Biscay, the productive field being 15 miles long and $2\frac{1}{2}$ wide. The ores are red and purple hematite, limonite, and carbonate, the iron content in the crude ores running from 45 to 56 per cent. The district has produced to date about 95,000,000 tons. The greater part of the

IRON ORES

Russian ore supply comes from the Ural Mountains, the ores on the east side of the range being magnetite, and on the west side limonite and carbonate. Near Krivoi Rog, in the Caucasus, are mines of hematite and magnetite. Fully 80 per cent of the iron ore of France is obtained from the minette beds of the Moselle that extend into Lorraine and Luxembourg. Most of the French ores are limonites. The principal Austrian iron mines are in Styria, the Styrian Erzberg having one of the largest deposits of siderite in Europe, yielding yearly about 1,000,000 tons of carbonate ore, containing 40 per cent of iron. In Bohemia are mines of magnetite, limonite, and siderite. Sweden has immense deposits of iron ore, chiefly magnetite with some specular hematite. The most important deposits are at Grangsberg in Central Sweden, where are specular hematite and magnetite ores containing 62 to 64 per cent iron and 0.9 to 1.5 per cent phosphorus, and at Gellivare, 100 miles from the Gulf of Bothnia, where are huge bodies of magnetite that run from 68.69 iron and 0.05 phosphorus to 60 per cent iron and 1.5 per cent phosphorus. The ores from this field and the neighboring districts of Kurunavaara and Luossavara will be of great importance to British iron-masters, and shipments to the Atlantic seaboard of the United States are quite possible.

WORLD'S PRODUCTION OF IRON ORE — METRIC TONS.

United States	29,350,325	37.7
Germany	16,570,182	21.4
Great Britain	12,475,700	16.1
Russia	6,700,000	8.6
France	4,260,747	5.5
Austria-Hungary	3,623,115	4.7
Sweden	2,793,566	3.6
Other countries	1,800,000	2.4
Total	77,573,635	100.0

The total production was undoubtedly larger, since among the "other countries" are those that collect no returns of mineral output. The figures are for 1901 or 1902.

The iron ore supplies of South America have been little developed, and those of Mexico are just coming into prominence. In the province of Santiago, Cuba, are deposits of high-grade hematite. From there over 690,000 tons were exported to the United States in 1902. At Belle Isle, N. F., beds of hematite are now worked on a large scale. In Ontario, Quebec, and British Columbia are deposits of good hematite and magnetite, and the Dominion will soon be a large producer. There is a possibility of iron ores being mined in Labrador.

The United States leads the world in the production of iron ore. The ores mined range from low grade limonite to the highest grade hematites and magnetites. The purest ore ever mined in the United States in quantity was probably the magnetite from the Lovers Pit at Mineville, N. Y., which ran 72 per cent iron in

carload lots, though the Lake Angeline mine at Ishpeming, Mich., has shipped hard hematite running 68 per cent iron and 0.008 phosphorus in thousand-ton lots. Minnesota now leads the States in production, with Michigan second, Alabama third, and Pennsylvania fourth. The chief centre of iron-ore production is about Lake Superior, where the ores occur along five mineral belts or "ranges," in Pre-Cambrian rocks. The Marquette range, in Michigan, was opened in 1856; the Menominee, mostly in Michigan, but partly in Wisconsin, in 1887; the Gogebic, in Michigan and Wisconsin, in 1884; the Vermilion, in Minnesota, in 1884; and the Mesabi, in Minnesota, in 1892. The ores shipped are nearly all red hematite. The Marquette produces some magnetite. As much of the ore is hauled long distances to a furnace, 60 per cent iron was once about as low grade ore as could be shipped profitably, but now some mines ship Bessemer ores containing but 45 per cent iron. The ore-bodies are sometimes of great size. The Chapin mine, on the Menominee range, is working lenses 100 feet wide and 600 feet thick in the middle, and 2,500 feet long. The Fayal mine, on the Mesabi range, in 1902 shipped 1,681,000 tons, and the Chapin in the same year 927,747 tons. The Mesabi deposits are flat-lying, covered by a varying depth of clay, sand, and boulders. By stripping off the surface and working the granular ore with steam-shovels, an enormous output is possible. The output of the various ranges in 1902 was: Mesabi, 13,342,840 long tons; Menominee, 4,627,524; Marquette, 3,853,010; Gogebic, 3,663,484; Vermilion, 2,084,263; making a total of 27,571,121 long tons.

In the South there are three important iron-mining centres—one near Birmingham, Ala., another in southeastern Tennessee, and the third in southwestern Virginia. The ores are red hematites and low-grade limonites. The growth of the Alabama industry is due to cheap ore, limestone and coking-coal being found in close proximity. Pennsylvania leads the Union in the production of magnetite, chiefly from the great ore-body at Cornwall, and also produces much limonite. New York and New Jersey also produce magnetite, and the former State some red hematite. Carbonate ores now come chiefly from Ohio. Of the western States, Colorado produces limonite, and in Utah and Wyoming are great deposits of magnetite and hematite, destined to be of importance in the near future. The famous specular hematite mines at Pilot Knob and Iron Mountain, Mo., are exhausted. Texas has large deposits of ore, and several other States are or will be important producers.

Mining and Handling Iron Ores.—Some extraordinary records of cheap mining and transportation have been made in the Lake Superior iron-ore trade. Large ore-bodies, effi-

UNITED STATES IRON ORE PRODUCTION — IN LONG TONS.

	1880	1890	1900	1902
Lake Superior	1,985,334	7,558,076	19,095,393	27,571,121
Southern States	627,517	2,904,322	5,100,000	4,850,000
Other States	4,884,658	4,056,469	1,758,000	2,215,000

IRON SKELETON CONSTRUCTION — IRONWEED

cient labor, and excellent management have been the factors in reducing mining costs, while the long lake-water haul, nearly 900 miles, in specially designed vessels, has made it possible to put down Lake Superior ores at Pittsburg, over 1,100 miles from the mine, at a total transportation cost of under \$2 per ton. On the Mesabi range, in some large mines steam-shovels load the ore directly upon the cars, one shovel having loaded 170,000 tons in 26 days, or at the rate of over 6,500 tons per day. The shovels are each operated by five men, and the labor cost for mining and loading averages but about 16c per ton, and at one mine which dug and loaded 293,651 tons in 174 days, the labor cost was only 4c per ton. The loaded ore-trains go 50 to 115 miles to a shipping port. There they are run on to long, high docks having large pockets or bins into which the ore runs through openings in the bottoms of the cars. From these pockets the ore passes by gravity down along chutes into the hold of the vessel, so that no hand-labor is required. The ore-pockets hold about 160 tons each, and number from 90 to 384, according to the length of the dock.

In unloading the ore from the vessels, the use of labor-saving machinery is even more notable. A series of steel bridges, easily moved along the docks, is supplied with hinged arms which can be lowered into the hatch of the vessel. Along each arm and across the bridge runs a trolley-train to which are attached automatic grabs similar to a double scoop. The grab or scoop holds about five tons of ore, and when it begins to draw together it digs into the ore. The grabs can remove over half of the cargo without any assistance, and the remaining half is brought directly under the hatch by use of a scraper, operated by similar machinery. The grabs are so controlled by the engineer that he can drop them at any point over the hold he may wish, and after a grab seizes its load of ore it is raised at full speed, carried rapidly along the trolley to any given point, and dumped into railroad cars or on stock piles. This 5-ton grab has a hoisting speed of 100 ft. a minute, and can run along the bridge at the rate of 1,000 ft. a minute. The bridges to which the arms with their grabs are attached are worked by electricity. By such a device 26 men can do the work of 300 under the old system. Another unloading device, the Hulett unloader, requires even fewer men, and takes out a larger proportion of the cargo without aid.

Bibliography.—Owing to the enormous growth of the iron industry, there is no recent single work covering the production and use of iron ores. Statistics of production can be found in 'The Mineral Industry,' the 'Mineral Resources of the United States,' and the 'Engineering and Mining Journal.' Descriptions of geological occurrence and mining methods can be found in the monographs and bulletins of the United States Geological Survey; and the 'Transactions' of the American Institute of Mining Engineers. See **GOETHITE**; **HEMATITE**; **ILMENITE**; **LIMONITE**; **MAGNETITE**; **MINING**; **ORE DEPOSITS**. **SAMUEL SANFORD**, *Assoc. Editor 'Engineering and Mining Journal.'*

Iron Skeleton Construction, a modern system of constructing high buildings, by which

architects and builders are enabled to plan and erect buildings as high as 15 or 20 stories on plots of ground 20 to 30 feet wide. By the use of this system the thickness of walls is considerably reduced, thus giving a larger floor space, a very desirable consideration, especially in office buildings. Iron and steel columns are carried up from foundation to roof, and then covered in with bricks or stone. Thus a carrying capacity equal to that of walls of much greater thickness is produced. A 12-story building in New York city thus constructed upon a lot 25 by 100 feet means a saving in floor space of thousands of feet.

Ironclad. See **ARMOR-PLATE**.

Ironclad Oath, The, an act passed by the United States Congress in 1866, excluding voters, in the States lately in rebellion, from the franchise. The act practically disfranchised all Southerners over 25 years of age. It was repealed shortly after its passage.

Irondale, i'rн-däl, Wash., a place in the northeastern part of Jefferson County, a few miles south of Port Townsend. The first blast-furnace on the Pacific coast was erected at this place in about 1880. The furnace was in operation about 12 years, and was then abandoned because of the great expenses incurred in production. The ore was obtained from Texada, an island belonging to British Columbia, and 130 miles distant. The last of the 19th century the Pacific Steel Company, a corporation in which practical iron-makers of Pennsylvania are the chief owners, began investigations as to the nature of the ore, and the possibility with improved machinery, to manufacture iron at Irondale or vicinity at paying rates. As a result the Pacific Steel Company have taken up the work abandoned by the Puget Sound Iron Company. The works have been so improved as to be practically new, and 20 brick charcoal kilns have been erected for the use of the company. Coke is obtained in Washington.

Ironton, i'rн-tôn, Ohio, city, county-seat of Lawrence County; on the Ohio River, and on the Detroit S., the Norfolk & W., and the Cincinnati, H. & D. R.R.'s; about 100 miles directly southeast of Columbus. The Chesapeake & Ohio railroad, in Kentucky, has here a ferry for passengers and freight, which practically gives the city the benefit of four important railroads. Ironton was settled in 1832, and for some years was known as a river-trading town. It was incorporated in 1849. It is situated in a section of country noted for its clay (suitable for pottery), iron ore, and bituminous coal. Its chief industrial establishments are foundries, rolling-mills, blast-furnaces, machine-shops, nail-works, furniture factories, and planing-mills. It has also among its manufactures doors and mantels, stoves, boilers, cement, and fire-bricks. The clay in the vicinity is much used for pottery. The parks, River View, Lincoln, and Beechwood, are attractive. Some of the principal buildings are the Briggs Public Library, the Kingsbury school, Odd Fellows' Hall, Masonic Temple, City hospital, and several churches. Ironton was the home for some time of the artist Sarah Cotter-King. Pop. (1900) 11,868.

Ironweed, a tall, coarse, composite plant of the genus *Vernonia*, three species of which

IRONWOOD—IRRIGATION

grow abundantly in woods and along roadsides throughout the southern half of the Union, bearing heads of magenta-colored flowers somewhat like miniature thistles. The most conspicuous species (*V. gigantea*) is often 10 feet high, and blooms in August and September. A similar species (*V. noveboracensis*) grows in low grounds throughout the northern States.

Ironwood, Mich., city in Gogebic County, on the Wisconsin C., and the Chicago & N. W. R.R.'s; about 12 miles south of Lake Superior and 33 miles southeast of Ashland. It was settled in 1884 and incorporated in 1887. It is situated in a region rich in iron ore and timber; the section is known as the "Gogebic iron region." The famous Norrie mine is in this vicinity. Ironwood is the trade centre for the greater part of the mining and lumbering business of the county. Some of the principal buildings are the Carnegie library, the city-hall, the high school, and several churches. Trolley lines connect the city with Gile and Hurley, Wis. The government is vested in a mayor, who is elected annually, and a council. The mayor appoints, subject to the approval of the council, all the subordinate officials except the members of the board of education. Pop. (1890) 7,745; (1900) 9,705.

Ironwood, a popular name for many trees whose timber is very hard and heavy. Probably the best known species in America is also known as leverwood, *Ostrya Virginica* of the natural order *Cupulifera*, indigenous from Nova Scotia to Florida and westward to Minnesota and Texas. It is a medium sized tree with furrowed bark, birch-like foliage, pistillate flowers in catkins resembling the female flowers of hop, hence its popular name hop-hornbeam. The name ironwood is also sometimes applied to *Carpinus Americana* or *Caroliniana*, of the same natural order. (See HORNBEAM.) Among foreign "ironwoods," perhaps the most widely known is *Mesus fere*, an East Indian tree planted around Buddhist temples for its fragrant flowers, which are used to decorate the images of Buddha. Another Asiatic species is *Metrosideros vera*, from which the Chinese and Japanese make rubbers. In Australia and South Africa various species of *Olea*, *Melaleuca*, *Sideroxylon*, *Notelaca*, and *Myrtus* are valued for their timber, locally called ironwood, employed where great toughness is desirable and weight no obstacle.

Iroquois, *ir-ō-kwoi'*, the name given by the French to the confederacy of North American Indians, called by the English the "Five," and afterward the "Six Nations." The Mohawks, Oneidas, Onondagas, Cayugas, Senecas, and Tuscaroras, after they were driven from their hunting-grounds in North Carolina in 1712, were the members of this confederacy. They formerly resided on the Mohawk River in New York State and on the lakes which still bear their names, and extended their conquests to the Mississippi and beyond the St. Lawrence. Their valor and successes had procured them the name of the Romans of America. Their territory abounded with lakes well stored with fish; their forests were filled with game, and they had the advantage of a fertile soil. The sachems owed their authority to public opinion; the general affairs of the confederacy were man-

aged by a great council, composed of the chiefs, which assembled annually at Onondaga. They exterminated the Eries, drove out the Hurons and Ottawas, subdued the Illinois, Miamis, Algonquins, Lenni Lenape, Shawanese, and the terror of their arms extended over a great part of Canada, and the northern and northeastern parts of the United States. It is probable that, had America not been colonized by the whites, they would have absorbed all the nations from Canada to the Gulf of Mexico. In the long wars between the British and French, which continued with some interruptions for nearly a century, until 1763, they were generally on the British interest; and in the Revolutionary War they were also mostly in favor of the British. According to the United States census, and a Canadian report, the total number of the Iroquois in 1902 was about 17,000, of whom about 8,000 were in the United States. See SIX NATIONS, THE.

Irrawad'y. See IRAWADI.

Irrigation, the watering of land by artificial means to make it productive. Historically, irrigation seems coeval with the earliest attempts to construct complicated machinery, and the systems of irrigation used in the earliest times in the Far East, in Babylonia, and in Egypt, dating in the last-named country 20 centuries before Christ, furnish as important a chapter in the history of invention as in the story of agricultural development. In our times the systems of India (q.v.) and Egypt (see ASSOUMAN; NILE) are probably the best organized, being largely under governmental control. In Europe, irrigation is widely used in northern Italy, southern France, and throughout Spain. The British colonial possessions of the southern hemisphere, notably Australia and South Africa, benefit more and more by artificial water-supply.

Early Irrigation in America.—Irrigation was practised in prehistoric times by the town-building Pueblo Indian tribes inhabiting portions of New Mexico and Arizona. The descendants of these Indians still utilize some of the lands which were tilled by irrigation at the time when the Spaniards first came from the south, and practise many of the primitive customs of their ancestors. The Mexicans of mixed Spanish and Indian origin, gradually extending their settlements from the south, through necessity practised irrigation. The early missions of the Pacific coast also used it, and in southern California particularly are to be found the ruins of substantial dams and headworks built of masonry and constructed by Indian labor. But the first systematic application of irrigation in the arid West by English-speaking people was made by the Mormons on the shores of the Great Salt Lake. The soil was so barren that crops could not be raised by ordinary means, and they turned the waters of the little cañon streams upon the ground where Salt Lake City now stands. After many years they succeeded in mastering the art of irrigation, and under the wise rules of Brigham Young, limiting the size of irrigated farms, the Mormons have become a prosperous people. At about the time the Mormons were settling Utah, the gold-miners in California were building ditches for placer-washing, and were using water from these ditches for irrigation. The results obtained attracted public attention, and irrigation slowly

IRRIGATION

developed as an adjunct to mining. With the stoppage of hydraulic mining, the ditches built for mining were either abandoned or used exclusively for irrigation. Many of them have been enlarged, and have now even greater value than in the old days of mining excitement.

Development in the United States.—The successful irrigation attained by the Greeley colony in Colorado, and the wonderful results shown by the Mormon communities in Utah, Idaho, and Arizona greatly stimulated the colony idea; many organizations brought people in large bodies from the Eastern States, and even from Europe, and placed them on small farms located near each other and supplied with water from a common ditch. Individual settlers also sought opportunities for bringing land under cultivation by artificial watering; and thus, at many widely scattered points, irrigation has been introduced. There are no statistics concerning the area irrigated in 1870, but it is probable that in that year there were not over 20,000 acres under irrigation in the whole United States; but 1870-80 saw a rapid development of small ditches, constructed by individuals and associations of farmers. At the end of that period there were probably 1,000,000 acres under irrigation. In the decade 1880-90 occurred the "boom" of speculative enterprise in irrigation canals. Large sums of money were obtained for irrigation works, but nearly all of these failed, and although they aided in the extension of irrigation, they did not enrich the investors. The 11th census showed that in 1889 there were 3,631,381 acres irrigated on 54,136 farms, with an average irrigation area of 67 acres. During the following decade the irrigated acreage doubled in extent. This was due to the extension and enlargement of the many canals existing in 1880, and to the more complete practice of irrigation on the lands under ditch.

In addition to the statistics obtained at the Eleventh (1889), and Twelfth (1899) Censuses, a special investigation was ordered in 1902 of irrigated farms and extent of irrigation in acres in the principal arid States, and also the total in the semiarid States, namely, North and South Dakota, Nebraska, Kansas, Oklahoma, and Texas. These lie east of the truly arid region but extend in parts into regions of deficient rainfall.

NUMBER OF IRRIGATED FARMS.

States	1902	1899	1889

National Irrigation Act.—The latest and most important step in American irrigation is marked by the National Irrigation Act, which was passed by Congress in 1902, and received the countenance of President Roosevelt. The act provides for the construction of irrigating works under the control of the secretary of the interior, the funds being derived from the disposal of public lands in the 13 States and 3 Territories. The public land is withdrawn from entry excepting under the Homestead Act. The holdings when reclaimed are to be restricted to between 40 and 160 acres, the area being limited to the acreage which in the opinion of the Secretary may be reasonably required for the support of a family. The cost of the reclamation works is to be apportioned to the reclaimed lands and is to be refunded in not exceeding 10 annual installments, the charges being determined with a view of returning to the Reclamation Fund the estimated cost of construction. For land in private ownership no right to the use of water shall be sold for tract exceeding 160 acres to any one landowner, and he must be an actual resident on or near the land. The result of the law is to give free land under the terms of the Homestead Law and supply water at cost from permanent systems without charging profit or interest to the settler. The management and operation of the irrigation works will ultimately pass to the owners of the lands to be maintained under such rules as may be acceptable to the Secretary, the title and operation of the reservoirs and similar works remaining in the government. It is believed that during each 10 years for the next third of a century an acreage equal to the total now under irrigation in all the West may be added to the agricultural area of the 16 States and Territories affected; thus rapidly multiplying production, furnishing new homes for millions, and providing the food products needed for shipment from the Pacific coast for use in the lands across the Pacific where new markets are now being opened for the surplus products of this country.

Upon the passage of the Reclamation Law in 1902, examinations and surveys were begun in the arid States and construction started in Arizona and Nevada. In Arizona flood water is to be stored on Salt River by a dam below the mouth of Tonto Creek, furnishing a supply for arid lands in the vicinity of Phoenix. In Nevada the flood water of Truckee River is to be diverted by a canal under construction taking it to Carson River, storage being there provided for the excess water of both streams. This will be used upon the desert area in the vicinity of Carson Lake. Other principal projects favorably reported upon are Colorado River in Arizona and California; Gunnison River in Colorado; Snake River in Idaho; Milk River in Montana; North Platte River in Nebraska; Rio Grande and Pecos rivers in New Mexico; Yellowstone River in North Dakota; Umatilla River in Oregon; Belle Fourche in South Dakota; Bear Lake in Utah; Palouse River in Washington, and Shoshone River in Wyoming.

IRRIGATION

Surface streams supply over 90 per cent of the irrigated land of the United States. Streams within the arid region of the United States rise high, and at one point or another flow for a time through upper valleys or parks. But after passing through rocky defiles to a fertile lower valley, the typical stream of the arid West loses itself in a shallow sandy channel.

Water-Supply and Regulation.—The water used in irrigation is for the most part taken from the river or creek by natural flow or gravity. The cost of lifting or pumping water is usually too great in proportion to the value of crops raised to permit the general use of pumps. Water will flow rapidly in a ditch having a fall of two feet per mile, and the stream supplying the ditch may be falling at a rate of 12 feet per mile. At the end of the first mile the water in the ditch will be 10 feet above that in the river, and at the end of the tenth mile will be 100 feet higher, and will thus cover land which is less than 100 feet in altitude above the stream at this locality. It is usual to construct some device at the upper end of each ditch or canal by which the amount of water entering from the river can be regulated. Without this, flood-waters would fill the ditch beyond its capacity, and would overflow and wash away the banks. In times of low water, also, the stream may fall to such an extent that it must be raised somewhat and forced into the ditch, and at all times it may be necessary to regulate the flow in order to apportion the water fairly to all concerned. In the case of the simplest ditch, a small dam of brush and stone is built diagonally or into or across the stream-bed as the water becomes low in summer, and this is made tight by means of sod and earth. More permanent dams are sometimes built of timber, or masonry. The head-gate or regulator of the canal placed at the end of the dam consists of a stout framework firmly bedded in the earth or rock with one or more openings, each of which can be closed by a gate sliding vertically. The water enters under the gates, the quantity being controlled by raising or lowering them.

A considerable slope can be used for small ditches, since the volume of water is not sufficiently great to move the large particles of sand and gravel. As a general rule, conduits of this character built in common earth should be so proportioned as to have an average velocity of a little less than three feet per second, or two miles per hour, when carrying their full capacity. It is necessary, therefore, to take into consideration the amount of water to be carried and from this deduce the size and shape of the cross-section of the canal or ditch in order to obtain the desired velocity. If the grade be excessive the seepage or loss of water becomes large. The shape of the cross-section of a canal depends largely upon the character of the surface soil. In light or sandy soil, where the earth is easily eroded, very gentle side slopes are given, while in harder materials the side slopes can be steeper. When the fall of the canal is so great that it is impracticable to allow the water to flow freely down the slope, devices known as drops are introduced. These consist of an arrangement whereby the water can drop to a lower level without injury to the canal. Drops are usually built of planks with a sharp overfall edge, and a low dam or obstruction below the fall in order to maintain the pool. Occasionally

they are made in the form of an incline, with a pocket at the bottom to break the force of the falling water. They are expensive to build, and difficult to maintain, because of the rapidity with which the timbers decay and the wearing action of the water, which constantly tends to cut exposed portions.

It is necessary in the construction of nearly every ditch or canal to take water across a depression at some point in its course. This is usually done by means of a flume or long box, usually rectangular and supported above the ground by a frame or trestle of timber or iron. Such flumes are often used across rocky ground where it is impracticable to dig a ditch. This is particularly the case near the head, where the water, after being taken from the river, is often carried through a narrow, steep-walled cañon. Here the foundation for a flume is prepared along the rocky cliffs, supports being devised to suit the inequalities of the ground. A better, though more expensive, type of flume is that having a semicircular section, and built of narrow planks or staves laid side by side and held in place by iron bands run around the flume, joined by nuts and threads by which the bands can be drawn up and the staves brought together. In crossing very deep depressions it is necessary to have a correspondingly high trestle in order to carry the flume across on grade. Such high trestles are expensive and liable to destruction from storms. In their place there have been built inverted siphons, wooden stave-pipe, or aqueducts of other form. The stave-pipes are similar in construction to the semicircular frame of narrow plank, carefully planned to a given dimension, and held in place by circular iron bands or hoops.

Application of Water.—The methods of irrigation practised in various parts of the United States differ with the climatic conditions and soil, and especially with the early habits of training of the irrigators. The methods of conserving and applying water have been improved under the stimulus of modern invention, although there has been little if any scientific or well-considered information available. Water is applied to the irrigated field in three ways—by flooding, by furrows, and by sub-irrigation.

Flooding.—This is done by the check system and by wild flooding. By the latter process the irrigator turns the water from a ditch over a level field and completely submerges it. Perfectly level fields are, however, comparatively rare, and the first step in primitive agriculture by irrigation has been to build a low ridge around two or three sides of a slightly sloping field, so that the water is held in ponds. These low banks are commonly known as levees or checks. In construction they are frequently laid out at right angles, dividing the land into a number of compartments. Water is turned from a ditch into the highest of these compartments, and when the ground is flooded the bank of the lower side is cut or a small sluice-way opened, and the water passes into the next field, and so on until each in turn is watered.

Furrows.—Irrigation in checks has gradually been given up, owing to the expense of leveling and leveeing the ground. With experience the irrigator has become able to apply water to crops which are cultivated in furrows, without resorting to such expensive means. The furrows are plowed in such a direction that the water

IRRIGATION

when turned into them from the lateral ditches will flow freely down them without washing away the soil. When the water has completely filled the furrows, and has reached the lowest points, the little streams are cut off and turned into another set of furrows. The methods of doing this differ. Sometimes the irrigator simply cuts the bank of the distributing ditch with a shovel and then closes the opening after sufficient water has escaped. A more systematic method is commonly employed in California. Water is carried to the furrows in a small box-flume with openings in the side. These openings are closed by little shutters and a number can be opened at once, permitting a certain quantity of water to escape into each furrow. The slope given the furrows determines to a certain extent the amount of water received by the soil. If the fall is very gentle, the water moves slowly and a large portion is absorbed while the furrow is being filled. If steep, the water quickly passes to a lower end and the ground does not absorb so much. When the entire field has been watered the furrows are usually plowed out and a thin layer of the top soil stirred to make an open, porous covering or mulch, preventing excessive evaporation and allowing the air to enter the ground. Without such cultivation a hard crust may be formed. The loosening of this crust breaks the capillary connection with the moisture beneath and thus lessens the loss of water. For irrigating small grain, such as wheat, the ordinary plow furrows are not used. The fields, brought to a uniform surface, are thoroughly cultivated, and after the grain has been sown, small parallel lines are made similar to furrows, but smaller and nearer together. These tiny channels are made either by a peculiar drag or by a roller upon which are projections so arranged as to make small grooves in the soil. These are made in the direction of the desired slope, so that the water can flow down the marks through the grain as it would in furrows through a cornfield. The rapidly growing grain shades the surface and prevents the formation of crust, rendering subsequent cultivation unnecessary. In order to cause the water to spread from the lateral ditches into the furrows through the ground, use is made of the tappoon—a small sheet of metal of such shape as to fit across the ditch. This can be forced into the soft earth, making a small dam and causing the water to back up and overflow the field of grain. Sometimes a canvas dam is used.

Furrow-irrigation is usually employed in watering trees and vines. In some localities, however, basin or pool irrigation is practised. The supply is conducted often in cement-lined ditches and by wooden flumes as near as possible to the trees and vines, and is then turned out into the furrows plowed around or near the trees. The water issuing from small apertures in the side of the wooden box falls into the furrows and is immediately conducted to the vicinity of the trees. Care is usually taken that the water shall not actually touch the tree-trunks, and it is extended far enough about the extremities of the roots to encourage these to spread outward. After the water has traversed the furrows to the lower end of the orchard, the supply is cut off, and the ground is tilled as soon as the surface dries sufficiently.

Sub-irrigation.—Attempts have been made to conduct the water beneath the surface imme-

dately to the roots of the trees, thus preventing waste by evaporation from the surface of the ground. Few devices have been successful, owing to the fact that the roots of the trees rapidly seek and enter the openings from which the water issues, or, surrounding the pipe by a dense network, cut off the supply. Porous clay tiling has been laid through orchards, and also iron pipes perforated so as to furnish a supply of water along their length. A machine has been invented and successfully used for making cement-pipe in place. Small trenches are dug through the orchard between the trees and the pipe-making machine deposits the material in the trenches, which are filled with earth as soon as the cement is set. Water is thus distributed underground where needed. In orchards where sub-surface irrigation has been unsuccessful because of roots stopping up minute openings beneath the surface, the system has been reconstructed and water has been brought to the surface at or near each tree by means of small hydrants. Vertical pipes are placed at short intervals leading to the level of the ground, and in these are small iron gates or shutters so arranged that the flow can be cut off in the buried pipe. For annual or root crops sub-irrigation has been successfully practised by the use of small iron pipes partly open at the bottom, allowing a small amount of water to escape. These pipes are laid 12 inches or more beneath the surface, and are connected with lines of tile or clay pipes leading from the reservoir or source of supply. As the crops are removed each year, and the ground cultivated, the roots have no opportunity to stop up the pipes. The term sub-irrigation is occasionally applied to conditions occurring in nature where water percolates freely beneath the ground for a considerable distance sufficiently near the surface to supply the need of crops. Where the subsoil transmits water freely, irrigation ditches may sub-irrigate large tracts of country without rendering them marshy. Thus farms may obtain an ample supply of water from ditches half a mile or more away without the necessity of distributing small streams over the surface. In the San Joaquin Valley, California, vineyards in certain localities are thus maintained in good condition, although water has not been visibly applied for many years.

Quantity of Water.—The amount of water required for raising crops varies according to the character of the soil. The plants themselves need a certain minimum supply, but a far larger quantity is required to saturate the surrounding soil to such a degree that the vitalizing processes can continue. Prof. F. H. King of Madison, Wis., has found by direct measurements that from 300 to 500 pounds of water are required for each pound of dry matter produced. When the ground is first irrigated an enormous quantity of water is sometimes required to saturate the subsoil. The quantity of water turned upon the surface during the first year or two has frequently been sufficient to cover the ground to a depth of 10 to 20 feet, and in some cases an amount equal to a depth of 5 feet or more per annum has been thus employed for several years. Gradually, however, the dry soil is filled. The pioneers of irrigation frequently use too much water, often to their disadvantage.

The quantity of water used in irrigation is usually stated in one of two ways: (1) In

IRRIGATION

terms of depth of water on the surface; (2) in quantities of flowing water through the irrigating season. In the humid regions the rainfall is usually from three to four inches per month during the crop season. In the arid region, where the sunlight is more continuous, and the evaporation greater, there should be for the ordinary crops at least enough water during the growing season to cover the ground from four to six inches in depth each month. The second method of stating the quantities necessary for irrigation is of convenience when considering a stream upon which there is no storage. It is estimated that one cubic foot per second, flowing through an irrigating season of 90 days, will irrigate 100 acres. One second-foot will cover an acre nearly two feet deep during 24 hours, and in 90 days it will cover 180 acres one foot deep, or 100 acres to a depth of 1.8 feet, or 21.6 inches. This is equivalent to a depth of water of a little over seven inches per month during the season of 90 days. Successive years of deficient rainfall in southern California from 1897 to 1900 served to prove that, with careful cultivation, crops, orchards, and vineyards can be maintained by using very small quantities of water. In some cases an amount not exceeding six inches in depth was applied during the year, this being conducted directly to the plants, and the ground kept carefully tilled and free from weeds. As estimated by various water companies in southern California, one miner's inch of water will irrigate from five to ten acres, the miner's inch equaling 12,960 gallons in 24 hours, or almost exactly 0.02 second-foot, this being the amount delivered under a 4-inch head, measured from the centre of the opening. Under this assumption one second-foot should irrigate from 250 to 500 acres. If it be assumed that one miner's inch is allowed for ten acres, or one second-foot for 500 acres, this quantity of water flowing from May to October, inclusive, will cover the ground to a depth of a little over seven tenths of a foot. The method of applying water largely governs the amount used. With alfalfa flooding is practised; with small grains the water is run in furrows; while with orchards the water is sometimes applied directly to each tree, or is run in furrows, four or five in each case between two rows of trees.

The annual charges for water by the acre in southern California, where this economy of water is practised, have been as low as \$3, and from this rising to \$15 or more per acre. For good farming in parts of the arid region outside of southern California, a depth of from 24 to 30 inches of water during the crop season should be sufficient. The usual charge for this quantity is from \$1.00 to \$2.00 per acre irrigated per annum. The temperature and the wind-movement introduce so many conditions that broad statements of this kind are merely suggestive, and not to be followed as rules.

Where an excessive amount of water is put upon irrigated land, as high as 70 per cent has been known to pass by seepage to the lower grounds. Growing plants evaporate in many cases 300 times their own weight of water each year. If a crop be carelessly cultivated and weeds allowed to grow with plants, the worthless plants waste as much water as is used by those that are valuable. But with careful cul-

tivation the evaporation is lessened and the waste of water is prevented. Thus the quantity of water required is only one half or one third of the amount needed where the farming is carelessly done.

Users' Rights.—The first settlers frequently laid claim to the whole flow of the stream. Soon after the first ditch was built others were constructed a few miles above or below. As long as the stream is of sufficient volume to fill each of the ditches, no difficulties from this arise; but sooner or later the increasing size and number of ditches and canals result in diminishing the flow in the river to such an extent that it becomes low, and water does not reach the ditches farthest downstream.

The result has been that in many parts of the arid region, owing to scarcity of water, lawlessness has prevailed, and every man has endeavored to obtain for his own crops as much as possible of the scanty supply. Usually the irrigators elected a water-master to apportion to each claimant a certain amount of water, or assign certain days or hours upon which water can be used. Often the quantity of the water has been settled only after vexatious lawsuits or neighborhood quarrels. In some parts of the arid region, notably in Wyoming and Colorado and Idaho, the States have undertaken the regulation of disputes, and have created special boards or tribunals to consider the matter and apportion water.

Methods of Obtaining Water.—In the arid region water can be obtained frequently by digging or boring wells at points near stream-channels or along the foot-hills. Out on the broad valleys it may be necessary to go to a depth of from 100 to 300 feet or more before reaching moisture. Where the supply of water from wells is ample, various devices have been employed, such as windmills and gasoline engines, for bringing it to the surface. It is very important to continue the borings through the water-bearing sands or gravel, so as to take advantage of the full thickness of the pervious deposits. Perforated pipe is often driven into the layers of coarse gravel, and adds greatly to the capacity of the well. Artesian or flowing wells may be sunk wherever water held under pressure in pervious material is overlaid by clay. In a well dug through the impervious layer into the gravel the water will rise to a height equal to the line of saturation of the gravel stratum in the surrounding country. Artesian conditions occur in nearly every State, but they do not extend over any considerable portion of the country, excepting on the Great Plains and in California. Wherever they occur the water has especial value on account of the convenience incident to its rising above the surface. In some places, as the James River Valley of South Dakota, the pressure is 100 pounds or more to the square inch, throwing the water to a considerable height and enabling the wells to be used as sources of power. The quantity of water to be had from deep wells is governed by the diameter of the well, the structure and thickness of the water-bearing rocks, and the pressure sustained by the water. With relatively dense rocks a slight head of water will throw only a feeble stream, but from thick layers of open gravel or sand rock large volumes are delivered. It frequently occurs that a 4-

IRRIGATION

inch pipe will deliver all of the water which can reach this point, and increasing the diameter of the well will not alter the flow.

While most of the water used in irrigation is diverted by gravity from flowing streams, yet, as regards value, it may be said that some of the most important sources of supply are utilized through pumping. In some localities where horses have little value, pumping by horse-power is in vogue. The practicability of irrigation in this way is limited largely by the depth of the water and the number of animals available. The force of flowing water itself is frequently employed to bring water up to the level of the irrigable land, the bucket-wheel having been utilized from the earliest historical times up to the present. The most important source of power for pumping water is wind. Over the broad valleys and plains of the arid region the wind-movement is almost continuous for days and weeks. It is a comparatively simple and inexpensive operation to sink a well into the water and erect a windmill, attaching this to a suitable pump. A windmill once erected on the plains is operated day and night by the wind, bringing to the surface a small but continuous supply of water. This small stream if turned out on the soil would flow a short distance, then disappear into the thirsty ground, so that irrigation directly from a windmill is usually impracticable. To overcome this difficulty it has been found necessary to provide small storage reservoirs or tanks, built of earth, wood, or iron, to hold the water until it has accumulated to a volume sufficient to permit a stream of considerable size to be taken out for irrigation. Such a stream, flowing rapidly over the surface, will penetrate to a distance and cover an area much greater than is possible with the small flow delivered by the pump. One disadvantage connected with the use of windmills is that most of them are constructed to operate only in moderate winds. As the strength of the wind increases, the wheel begins to revolve, increasing in efficiency until the velocity of the wind is about eight or ten miles an hour. At greater speed the mills are usually so constructed that the efficiency decreases rapidly as the wind becomes more powerful. When it approaches a gale, the mill stops completely.

In many places drainage-works are a necessary adjunct of irrigation. On bench-lands or gently sloping hillsides the water which escapes from one man's farm is eagerly caught and used by his neighbor below, and there is none left to stagnate, the surplus from the cultivated lands being often of great value in watering the lower meadows. There are cases, however, where the question of disposing of the water is as important as that of obtaining it. These are on the nearly level lands, where the subsoil has been filled to saturation by the water which has no opportunity to escape, and expensive works are required in order to redeem the lower lands for agricultural purposes.

Duty of Water.—The amount of land which can be irrigated with a given quantity of water, or the relation which these bear to each other, is commonly expressed by the term duty of water. The investigation of the duty of water is one of the most complicated problems of irrigation. There is such a difference in methods of measurement, localities, soils, crops, ap-

plication of water, and frequency of watering that the statements made by different persons are almost irreconcilable. In general, more water is used, or the duty is less, on the newer land than on that which has been cultivated by irrigation for some years. The rainfall also affects the quantity used, and as this is exceedingly irregular, the amount of water applied each year fluctuates. Seepage likewise complicates matters, for a field may often receive considerable water indirectly and require less by direct application. The duty of water is quoted at from 30 to 500 acres or more to the second-foot. For convenience the unit of 100 acres to the second-foot has been considered as indicating careful irrigating, although in the more southwestern portion of the arid region this would be considered low, and in the northern part high.

Since the value of water per second-foot varies largely with its duty, it will be recognized that it is exceedingly difficult to estimate. However, it is necessary to arrive at certain averages in order to approximate the possible values of river, or of storage basins, in the future development of the country. It has been estimated that a perpetual water-right is worth from \$25 to \$50 per acre in a grain or grazing country, and as high as from \$100 to \$500 per acre for fruitland, rising in southern California for the best citrus lands even to \$1,000 or more per acre.

Alkali.—The accumulation of alkali in irrigated lands presents one of the most serious problems encountered in this method of agriculture. The injuries from the presence in excess of earthy salts are usually evident in the corrosive action of the tender bark, especially at the root-crown. Experiments made in California show that apple-trees are severely injured by the presence of 3,000 pounds of common salt per acre, this amount being disseminated through four feet in depth. On the other hand, the olive thrives at Tulare, where the soil contains as high as 5,600 pounds of salt per acre. Alfalfa, when young, is easily killed by alkali, but it has been found to thrive in soil containing as much as 6,000 pounds of common salt, 3,000 pounds of carbonate, and over 1,000 pounds of sulphate, per acre, distributed through six feet in depth. Sugar-beets also have been known to grow well where a large amount of alkali is present. Grapes apparently are least affected by small amounts of alkali, while peaches and lemons are more susceptible to injury because of its presence. The recently introduced salt-bush is notable for its ability to grow in alkaline lands, and sorghum and alfalfa, especially when the latter has reached maturity, are almost equally vigorous.

The most effective way of removing alkali is by underdrainage through tiles laid at a depth of from three to five feet, the drainage-water being allowed to escape into a stream, or into a well from which it can be removed by pumping. Recent authorities on the subject claim that the trouble caused by alkali yields sometimes to careful treatment, and that science has partly solved the problem. It is shown that the tiling of land for alkaline washing costs no more than drain-tiling as practised on eastern farms. In the government demonstration at Salt Lake City, where the percentage of alkali is enormous, the lines of tile are 150 feet apart. The water de-

IRRIGATION BILL.—IRVINE

scending into the soil dissolves large quantities of alkali near the surface and carries it off in solution. Land so tiled, even if badly alkaline, can be returned to profitable cultivation in time if heavily irrigated, and within one year can be used for the production of some crops suited to the climate. Large areas of alkali land in the West may be reclaimed at a cost below the actual increase in the value of the land. It is thought that the time will soon come when drainage will be as common in the irrigated districts as are the tile-drained fields of the Middle West.

States Compared.—In the number of irrigators California stands far ahead of any other State, having about one fourth of the total number in the United States. Colorado, however, exceeds in the number of acres irrigated, although not in the value of irrigated crops. In this respect California leads, having a value double that of Colorado, and over one third that of the total value of irrigated crops in the United States. The greatest percentage of increase in the number of irrigators has been in the State of Washington, and the least in Oregon. This, doubtless, is due to the fact that in irrigation Oregon reached a certain culminating point previous to 1889, while in Washington the construction of ditches had only begun.

Comparison of Crops.—In considering the character and value of the crops produced on irrigated land in the arid States and Territories, hay and forage form the most important item, being over one third of the whole. Cereals—principally wheat, oats, rye, and barley—come far below the forage crops; and next to these in order are vegetables, orchard fruits and small fruits. In California only the orchard fruits surpass the forage crops in value. The large production of hay and forage under irrigation illustrates the fact that in these States irrigation is, to a large extent, an adjunct of stock-raising. The production of cereals under irrigation is relatively small. In California, for example, only 6.0 per cent of the wheat is irrigated, and 8.0 per cent of the barley. The total value of all the cereals produced under irrigation in the United States is far less than that of those produced in almost any one of the humid States of the East; in New York, for example, though it is not considered a farming State, the value of the cereals raised is more than double that of the entire amount produced under irrigation in the whole country. In many localities the irrigation of cereals and staple crops has been brought about by local conditions, such as difficulty of transportation and consequent heavy cost of importation. The irrigated cereals in such localities are raised almost wholly for local consumption, and do not enter the markets of the world.

Economic Bearings.—Irrigation has important economic aspects especially seen in the greater success of the small irrigated holding. The Salvation Army, following the example of the Mormon colonies of 1847 in Utah, and of the Greeley community in California, has located small communities on reclaimed farms. The process of colonization will always be slow from the nature of the case, and the effect on eastern agriculture, far from being sudden and severe as was urged by the opponents of the Irrigation

Bill in 1902, will be gradual. It may be very beneficial in forcing eastern farmers to more careful use of their water-supply, and perhaps to the adoption of a modified scheme of irrigation, which has been found to increase crops even in humid districts, and which would at least be a valuable resource in times of drought.

Irrigation Bill, or Reclamation Act, a Federal measure, dated 17 June 1902, for the reclamation by irrigation of arid and semi-arid lands in Arizona, California, Colorado, Idaho, Kansas, Montana, Nebraska, Nevada, New Mexico, North Dakota, South Dakota, Utah, Washington and Wyoming. See **IRRIGATION**.

Irish, ir'tish, a river of Asia, which rises in China, in the Altai Mountains, and after expanding into Lake Zaisan, flows through the Russian territory of Semipalatinsk, passes the town of Tobolsk, and finally, after a course of about 1,800 miles, joins the Obi near Samarova. Much of its course is through low plains and steppes, and its navigation is much impeded by shifting sands. Its fisheries, particularly of sturgeon, are very productive.

Irvine, William, American Revolutionary general: b. near Enniskillen, Ireland, 3 Nov. 1741; d. Philadelphia 29 July 1804. Having graduated at Dublin University, he studied medicine and surgery, and was appointed surgeon on board a ship of war, serving during a part of the war of 1756-63 between Great Britain and France. On the declaration of peace he emigrated to America, and in 1764 settled in Carlisle, Pa., where for 10 years he practised his profession. At the opening of the Revolution he took part with the colonies, was a member of the provincial convention assembled 15 July 1774, until he was appointed by Congress, 10 Jan. 1776, colonel of the 6th battalion of the Pennsylvania line. On 12 May 1779 he was promoted to the rank of brigadier-general, and assigned to the command of the 2d brigade of the Pennsylvania line. In the autumn of 1781 he was ordered to Fort Pitt, to take command of the troops on the western frontier, and continued to fulfil the duties of this post until after the war had closed. He was early in 1785 ap-

IRVING

pointed by the State agent under an "act for directing the mode of distributing the donation lands promised to the troops of the commonwealth." About this time he suggested to Pennsylvania the purchase from the United States of the tract of land known as "the triangle," thus giving to the State an outlet upon Lake Erie. He was a member of Congress under the confederation 1787-8, and of the Federal Congress 1793-5. In 1794 he was assigned to the command of the Pennsylvania troops for the purpose of quelling the "whiskey insurrection," and in all the most important movements in connection with this subject took an active part. He was president of the State society of the Cincinnati at the time of his death.

Irving, ér'vīng, Edward, Scottish preacher, founder of the religious sect known as Irvingites: b. Annan, Dumfriesshire, 4 Aug. 1792; d. Glasgow December 1834. He was graduated at the University of Edinburgh, and in 1815 became a licentiate of the Church of Scotland and subsequently Dr. Chalmers' assistant. In 1822 he became minister of the Caledonian Asylum chapel in Cross Street, Hatton Garden, London. Here he soon attracted very large congregations by the force and eloquence of his discourses, and the singularity of his appearance and gesticulation. The greatest orators and statesmen of the day crowded with the wealthy and fashionable to hear him. The appearance of the preacher — tall, athletic, and sallow — displaying a profusion of jet-black glossy hair reaching to his shoulders, with a singular obliquity in one of his eyes, and a stern calm solemnity of aspect, enhanced the interest and excitement produced by his discourses. His phraseology was one of the peculiarities which gave him *éclat* with the public, for he expressed his ideas in the language of Milton, Hooker, and Jeremy Taylor. At London he began to publish books in which he broached novel theological views. 'Sermons, Lectures, and Occasional Discourses,' in which his theological peculiarities were first distinctly enunciated, were published in 1828. In the beginning of 1832 his aberrations had become so marked and extraordinary that his hearers, who in 1829 had erected for him a large church in Regent Square, preferred charges against their minister. On 2 May 1832 the London presbytery unanimously found him guilty of error. The consequence was that he became dispossessed of his cure. In 1833 the presbytery of Annan, which had licensed him, deposed him from the ministry, on which occasion his defense of himself was a sublime effort of oratory. He retired to Scotland, broken in health and spirits, and was attacked with consumption. For the religious sect he founded see CATHOLIC APOSTOLIC CHURCH. His life has been admirably written by Mrs. Oliphant.

Irving, Sir Henry (originally JOHN HENRY BRODRIBB), English actor: b. near Glastonbury 6 Feb. 1838. He was for a time a clerk in London, but adopted the theatrical profession, his first appearance being at Sunderland in 1856. He appeared for the first time in London at the Princess' Theatre, in 1859, after which he went to Manchester, where he remained for five or six years, but returned to London in 1866, where his first marked success was as Digby Grant in Albery's 'Two Roses' (in 1870), which was

followed by his powerful impersonation of Mathias in 'The Bells.' His next noteworthy parts were Charles I., Eugene Aram, and Richelieu, in the plays so named. In 1874, at the Lyceum Theatre, he sustained the part of Hamlet so successfully as to raise himself to the first place among English actors. His chief Shakespearian parts are Macbeth, Othello, Shylock, and Richard III. In 1878 he leased the Lyceum Theatre for himself, and has since put on the stage in excellent style 'Othello,' 'The Merchant of Venice,' 'Much Ado About Nothing,' 'Romeo and Juliet,' 'Twelfth Night,' 'Faust,' 'Macbeth,' etc., playing in them the principal character with Miss Ellen Terry. His appearances in the provinces have been equally successful with those in London, and he has met with like favor in his repeated visits to the United States. Of his more recent roles may be cited Becket in Tennyson's play of that name (1893), King Arthur in a play of that name (1895), Napoleon in 'Madame Sans-Gêne' (1897), the title role in his son's play of 'Peter the Great' (1898), and Robespierre in a play of that name (1899), specially written for him by M. Victorien Sardou, and the title role in 'Dante' (1903). He was knighted in 1895, and in 1898 Cambridge University conferred on him the honorary degree of LL.D.

Irving, Washington, American author: b. New York 3 April 1783; d. Tarrytown, N. Y., 28 Nov. 1859. His father, William Irving, merchant, came to New York from the Orkneys in 1763, having married Sarah Sanders, daughter of Cornish parents, two years before. Washington was the youngest of their 11 children. His school training was far from thorough, and was not directed toward academic culture — though two of his brothers had been sent to Columbia College — a decision of his father that he much regretted in maturer years. He made up for his lack of interest in school subjects by enthusiastic reading in English authors, particularly Chaucer and Spenser. At 16 he entered a law office, and in 1802 began authorship by contributing humorous sketches, over the name of "Jonathan Oldstyle," to *The Morning Chronicle*, a daily edited by his brother Peter. Developing symptoms of consumption, he sailed in 1804 for France, and spent two years in travel, on the continent and in England, which restored his health. On return he was admitted to the bar, but instead of practice began, in 1807, with his brother William, and James K. Paulding, the issue of 'Salmagundi,' the success of which determined his career, and the immediate character of his writing. At the close of the next year he set about reshaping the burlesque history of New York, which he had begun, with Peter Irving, some time before on a different plan. While in this work he met with the great affliction of his life, the loss of his betrothed, Matilda Hoffman, daughter of a prominent lawyer of the city, in whose office he had finished his legal studies. The completion of the book, 'Dietrich Knickerbocker's History of New York,' published in 1809, was the only solace that he permitted himself in the first months of seclusion and grief. In 1810 he wrote a short life of the poet Campbell, and was received into partnership by his brothers Peter and Ebenezer, who were founding an importing house, and wished to provide

WASHINGTON IRVING.

IRVINGITES — ISAAC

Washington the means, without contribution of time or labor to the business, of preparing himself more fully for his chosen work. In 1813 and 1814 he edited the 'Analectic Magazine,' published in Philadelphia, and contributed biographical articles upon some of the naval commanders in the war then in progress with Great Britain. After the burning of our national capital in 1814, he offered his services to his native State, and was made aide-de-camp to Governor Tompkins, with the rank of colonel. At the close of the war he sailed for England, and was received with distinction by the American artists Allston and Leslie, and by Scott, Campbell, Moore and other literary men. In 1818 the firm of P. and E. Irving and Co. failed, and Washington's pleasant rambles in England and Scotland came to an end. He declined a post in the navy board, at home, and set himself at work in London with his pen. Early in the next year he sent over for publication in New York and Philadelphia, the first number of the 'Sketch Book,' containing 'The Voyage,' 'Roscoe,' 'The Wife,' and 'Rip Van Winkle.' Other numbers followed, the success was great, and in 1820 John Murray brought out an edition of the work in London. Its popularity with British readers was such that Murray became the first publisher of 'Bracebridge Hall' (1822), 'Tales of a Traveller' (1824), and other works. In 1826 Irving went to Madrid, at the instance of his friend, Alexander H. Everett, American minister to Spain, who advised the translation of Naverrete's 'Voyages of Columbus,' then issuing in parts. Irving found the work impracticable to translate, being a collection of sources rather than a consistent narrative, and prepared instead the 'History of the Life and Voyages of Christopher Columbus,' finished in 1828. This first serious product of Irving's powers retained much of the ease and charm of 'The Sketch Book' and 'Tales of a Traveller,' and was eminently adapted to increase his fame. It was not especially successful, though Murray paid 3,000 guineas for the copyright; an abridgment of the work had a better sale. 'The Conquest of Granada' (1829), 'Companions of Columbus' (1831), and 'The Alhambra' (1832) were further fruits of his Spanish studies and travel. In the meantime he had been made secretary of legation (1829), in London, and received the medal of the Royal Society of Literature (1830), and the degree of LL. D. (1831) from Oxford. In 1832 he returned to America, but not to rest. He accompanied an Indian commission to Fort Gibson, on the Arkansas River, and wrote 'Tour on the Prairies,' published as the first volume of 'Crayon Miscellanies,' in 1835. The second volume, 'Abbotsford and Newstead Abbey,' and the third, 'Legends of the Conquest of Spain,' followed in a few months. He now bought the little Van Tassel farm, at Tarrytown, and began to enlarge its Dutch cottage, and improve the grounds. To this home, called "Sunnyside," he soon removed from the city, and eventually brought to it the brothers who had aided him in earlier years. In 1836 he finished 'Astoria,' with the help of his nephew, Pierre M. Irving, from materials furnished by John Jacob Astor. The next year he published 'The Adventures of Captain Bonneville,' properly a continuation of the preceding. He then began a history of the conquest

of Mexico, but on learning that W. H. Prescott was at work on the same subject, resigned the task to him. In 1839 he engaged to write for the 'Knickerbocker Magazine,' and furnished monthly articles for about two years. In 1842 he was appointed Minister to Spain, and for the next four years wrote little. On return he arranged with G. P. Putnam for a complete edition of his works, in 15 volumes, to which he added (1849) the 'Life of Goldsmith,' and (1850) 'Mahomet and his Successors.' The way was now open for the 'Life of Washington,' which had long been contemplated. In 1855 appeared 'Wolfert's Roost,' mainly a reprint of the Knickerbocker papers, and two volumes of the 'Life.' The work told on his strength, and the fifth and last volume, finished in March, 1859, left him a broken man. His death was from heart disease, in his 77th year. He was buried by the side of his mother, whose tastes he had inherited, and whose sympathy and nurture had made him what he was. His authorship was the outcome of his personal character, and was little modified by the literatures of the world. With all his graces of expression, he lacked the gift of deep insight, and failed to achieve much vigor of style. The best biography is still the 'Life and Letters' by his nephew, Pierre M. Irving (1863). Consult also Warner, 'Washington Irving' (1881); Laun, 'Washington Irving: Ein Lebens- und Charakterbild' (1870); Richardson, 'American Literature' (1887-8); Wendell, 'A Literary History of America' (1900).

The University of Nebraska.

Ir'vingites. See CATHOLIC APOSTOLIC CHURCH.

Ir'vington, N. J., a town in Essex County, adjoining Newark on the southwest. It is a pleasant residential suburb of that city, and also has a number of manufactories, among which are smelting-works and establishments for making wall-paper, pocket-book frames, tools, brushes, rules, etc. The town was incorporated in 1898, although its settlement dates back almost to 1660. Its governmental affairs are in the hands of a town council. Pop. (1900) 5,255.

Irvington, N. Y., village in Westchester County, on the Hudson River, and the New York C. & H. R. railroad, 23 miles north of New York, and a short distance south of Tarrytown; named in honor of Washington Irving. It is mainly a residential village of recent growth and is noted for its beautiful dwellings and grounds, with their fine situation on the river-bank. These are largely the homes of New York business men and their families. The Guitéau Library and the town-hall are among its most noteworthy buildings. The village is a place of great interest as being the location of "Sunnyside," for many years the home of Washington Irving. The house, half a mile north of the railroad station, "is a many-gabled, vine-clad cottage, covered with stucco, and shadowed by grand trees." It has been rebuilt and enlarged. Pop. (1900) 2,231.

Isaac, i'zak (Heb. "he will laugh"), Hebrew patriarch, the son of Abraham by Sarah, so called to denote the laughter and gladness occasioned by his birth. He is remarkable for his miraculous escape from death as a burnt-

ISAAC—ISAIAH

offering; and for the fraud perpetrated upon him, at his wife Rebecca's instigation, by his son Jacob, to the injury of Esau. He died at Hebron 180 years old, and was buried in the cave of Machpelah, the resting-place of Sarah and Abraham, and of Rebecca.

Isaac I., Comnenus, Byzantine emperor: d. 1061. He was the son of Manuel Comnenus, an eminent general under Basil II., emperor of Constantinople, and was the first of his family to assume the purple. He had distinguished himself as a soldier and commander in the wars against the Arabs in Asia Minor, and had married a captive Bulgarian princess. In 1057 he succeeded to the throne upon the deposition of the aged and incompetent Michael VI. He strengthened the frontiers of the empire against the Arabs of the south and the nomad tribes of the Don and Dniester on the north; he also improved the financial condition of the government by an impartial imposition of taxes on all ranks of life. He abdicated in 1059 and spent the remainder of his life in a monastery. He was a learned student of Greek literature, one of the ablest and best of the Byzantine emperors and was succeeded by Constantine X., Ducas, the second of the Comnenian dynasty.

Isaac II., An'gelus, Byzantine emperor: d. 1204. He became sovereign of the East in 1185, and reigned 10 years. Isaac was a vicious and cowardly prince, and was dethroned, blinded, and imprisoned by his brother Alexius in 1195. Eight years later he was restored to the throne and reigned for six months, when he was again dethroned, and soon after died in prison.

Isaak Church, The, the finest building in Russia, or in northern Europe, begun by the Empress Catherine, and finished by Nicholas I. The foundation alone is said to have cost \$1,000,000. It is a magnificent structure, one of the most remarkable sights of the Russian capital. The design is simple and majestic, the whole being surmounted by a gilded dome. The total cost of the structure was \$67,500,000.

Isaaks, Jorge, Hor'hā ē'säks, Colombian novelist and poet: b. Cali, State of Cauca, Colombia, 1843; d. 1895. He was the son of an English Jew who had married a Spanish woman and was taken to Bogotá in childhood, and ever after made it his home. He published a volume of poems in 1864, and in 1867 his masterpiece, the novel 'Maria,' a story of domestic life in Colombia, told with consummate skill and tender simplicity.

Isabela, ē-sā-bā'lā, Philippines, province of Luzon, on the northern Pacific coast of the island with Cagayán on the north and Príncipe and Nueva Ecija on the south; length 118 miles; area 5,395 square miles (including dependent islands), the largest province of Luzon. The Sierra Madre mountain range runs parallel to the coast, a short distance inland; the rest of the surface is broken by low hills; the Grande de Cagayán River traverses the entire length of the province; and the main highway from Aparri to Manila parallels this river. Rice, sugarcane, chocolate, coffee, corn and vegetables grow with little cultivation; tobacco is extensively raised and its growth and treatment is the most important industry; this tobacco is regarded as the best in the Philippines and is the chief export of the province. Cattle raising is

also an important industry. Civil government was established in 1901, and the people have shown themselves generally friendly to it. Pop. 48,300.

Isabella (iz-a-bel'a) (I.) of Castile, queen of Spain, daughter of John II., king of Castile and Leon: b. Madrigal 23 April 1451; d. Medina del Campo 26 Nov. 1504. She married, 19 Oct. 1469, Ferdinand V., king of Aragon (q.v.), surnamed "The Catholic." After the death of her brother, Henry IV., in 1474, she ascended the throne of Castile, to the exclusion of her elder sister, Joanna. During the lifetime of her brother Isabella had gained the favor of the estates of the kingdom to such a degree that the majority, on his death, declared for her. After the kingdoms of Aragon and Castile were thus united, Ferdinand and Isabella assumed the royal titles of Spain. She was always present at the transaction of state affairs, and insisted that her name should be placed beside that of her husband in public ordinances. The conquest of Granada, after which the Moors were entirely expelled from Spain, was in a great degree her work; and the encouragement she gave Columbus assisted him to the discovery of America. In all her undertakings Cardinal Ximenes was her assistant. She has been accused of severity, but a spirit like hers was necessary to humble the haughtiness of the nobles without exciting their hostility, to conquer Granada without letting loose the hordes of Africa on Europe, and to restrain the vices of her subjects, who had become corrupt by reason of the bad administration of the laws. She checked private warfare, which had formerly prevailed to the destruction of public tranquillity, and introduced a vigorous administration of justice. In 1492 Pope Alexander VI. confirmed to the royal pair the title of "Most Catholic," already conferred on them by Innocent VIII. The zeal for the Roman Catholic religion, which procured them this title, gave rise to the Inquisition, which was instituted in Spain in 1480, at the suggestion of their confessor, Torquemada. See FERNAND V., XIMENES, and COLUMBUS. Consult Prescott, 'History of the Reign of Ferdinand and Isabella the Catholic.'

Isabella II., ex-queen of Spain, daughter of Ferdinand III.: b. Madrid 10 Oct. 1830; she succeeded her father in 1833, her mother being appointed queen-regent. The early years of her reign were disturbed by a rising in favor of her uncle, Don Carlos, who, if the Salic law had not been set aside, would have ascended the throne instead of her; but this was quelled in 1839. She was declared of age in 1843, and in 1846 was married to her cousin, Don Francisco d'Assisi (q.v.). Her reign was so despotic that a revolution took place in 1868, which drove her from the country. She resigned her claims to the crown in favor of her son Alfonso, who ascended the throne in 1875 as Alfonso XII.

Isabella the Catholic, Order of, a Spanish order of knighthood founded by Ferdinand VII. in 1815 as a reward for loyalty in defense of the Spanish-American colonies. It is now conferred for all kinds of merit. The badge of the order is an eight-pointed cross of gold.

Isabellita. See BUTTERFLY-FISH.

Isaiah, i-zā'yā or i-zī'yā (Heb. YESHA-YAHU, Salvation of Jehovah), the first of the

ISAR—ISINGLASS

four great Hebrew prophets who lived in the days of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah. Of the circumstances of his life almost nothing is known, further than that he had an important influence over the kings and people. As his ministry commenced before the death of Uzziah, he must have been at the least 80 or 90 at the accession of Manassch. His residence seems to have been at Jerusalem, and he lived about 740–700 B.C. He had three sons, given to him “for signs and wonders in Israel.” As there is a manifest want of a continuous unity of design in the prophecies of Isaiah, a controversy has arisen as to who was the compiler of the book. The obvious answer, that it was Isaiah himself, assisted by a scribe, has been accepted by many, whose opinion is fortified by 2 Chron. xxxii. 32, from which it appears that Isaiah was otherwise an author. It is admitted that the “visions,” which were seen at different times, are not arranged in exactly chronological or material order; but an attempt has been made to account for this on the hypothesis of an original work with subsequent modifications. The dispute, however, with regard to the arrangement of the prophecies sinks into insignificance in comparison with that concerning their authorship. As the last 27 chapters seem to have been written in the time of the Babylonian captivity, they have been ascribed to a later “Isaiah,” and coherence of structure and unity of authorship have not been denied to them. The impugners of the Isaiah authorship rely for argument on the author having taken his standpoint at the close of the Babylonian captivity, and on his knowledge of the career of Cyrus, who lived more than a century after the death of Isaiah. A difference of style and sentiment is also urged as militating against the commonly accepted authorship. The argument on the other side is drawn from the predictive character of prophecy, and from the nature of “vision,” in which the prophet sees the future as if it were the present. The style of Isaiah unites simplicity and clearness with dignity and majesty. In fulness and power, he far surpasses all the other prophets. His writings are chiefly denunciations and complaints of the sins of the people, threats of approaching ruin, and anticipations of a more glorious future. The whole bears the stamp of genius and true inspiration, and is marked throughout by nobleness of thought and feeling. See Driver, ‘Isaiah, his Life and Times,’ and the commentaries by George Adam Smith and Marti.

Isar, ē'zär, a river of Germany, which rises in the Tyrol, enters Bavaria, flows past Munich to Freising, where it passes the towns of Landshut and Landau; and joins the right bank of the Danube a little below Deggendorf. Its length is about 190 miles. The current is extremely rapid, and is much used for floating timber.

Isarog, ē-sā-rög', an isolated mountain of the island of Luzon, Philippines, near the centre of the province of Ambos Camarines (Sur); it is an extinct volcano, height 6,450 feet. It lies between Lagony Gulf and Miguel Bay, and is the apex of the irregular mountain system which forms the watershed between these two bodies of water. It is 36 miles in circumference at the base, and a well built road makes a complete circuit of it.

Ischia, ēs'kē-ä, an island of Italy, 26 square miles in extent, in the Gulf of Naples. It is entirely volcanic in character, and is noted for its warm mineral springs and volcanic convulsions. In 1881 and 1883 earthquakes caused great loss of life and property. The capital, Ischia, with some 7,000 inhabitants, is a favorite resort of tourists. Other towns are Casamicciola and Forio, both of which suffered severely in 1883. Pop. (1901) 26,690.

Ish'maelites, the descendants of Ishmael, the son of Abraham by Hagar. These are to be found among the Arabians, as physical characteristics and language prove beyond a doubt. The Joktanite and Cushite monarchies in southern Arabia give no indication in character and habits of having had Ishmaelites as founders, but the Bedouins who roam over the deserts lying between the Peninsula of Sinai and the Persian Gulf, are unquestionably of Ishmaelic origin. They maintain a primitive and patriarchal form of life, and are full of Ishmaelic traditions.

Ishmailis, ish-mā'lēs, one of the 72 heretical sects of Mohammedanism (q.v.).

Ish'peming, Mich., city in Marquette County; on the Duluth, S. S. & A., the Chicago, M. & St. P., and the Chicago & W. R.R.'s; about 14 miles west of Marquette, and 58 miles north by west of Escanaba. It was settled about 1856 and received its first charter in 1857. It is situated in the great iron ore region of Michigan, and is the centre of the iron ore mining industry of the State. Gold and marble are found in the vicinity and an excellent building stone. The manufactures are chiefly the machinery used in mining. The school buildings rank in architecture and equipment with the best in the State. Pop. (1890) 11,197; (1900) 13,255.

Isinglass, a form of gelatine (q.v.), whitish firm in texture, and of great purity, prepared mainly from the sounds or air-bladders of different species of fish, especially of the Russian sturgeon and, in this country, of cod, sturgeon, hake, etc. In some cases the skins are also used for this purpose. Besides Russia, from which it has been principally obtained, the United States and Canada, Brazil and the East Indies furnish considerable quantities to commerce, as do also Manila and the West Indies. It is the basis of the Russian glue, preferred to all other kinds for strength. Isinglass receives its different shapes in the following manner: The sounds are taken from the fish while sweet and fresh, slit open, washed from their slimy matter, divested of a very thin membrane which envelops the sound, and then exposed to stiffen a little in the air. In this state they are formed into rolls about the thickness of a finger, and in length according to the intended size of the staple; a thin membrane is generally selected for the centre of the roll, around which the rest are folded alternately, and about half an inch of each extremity of the roll is turned inward. Isinglass is best made in the summer, as frost gives it a disagreeable color, deprives it of its weight and impairs its gelatinous principles. Boiled in milk, it forms a mild nutritious jelly, and is thus sometimes employed medicinally. It is used in making court-plaster, cement, mock pearls, and many other articles, also in clarifying fermented liquors for improving soups,

ISIS — ISLAND

jellies, etc., and as sizing for linens, silk, gauzes, and other fabrics.

Isis, the principal goddess of the Egyptians, the sister and wife of Osiris, representing the moon, as Osiris did the sun. The Egyptians believed that Isis first taught them agriculture. She is represented in various forms. In one she has the form of a woman, with the horns of a cow, as the cow was sacred to her. She is also known by the attributes of the *lotus* on her head, and the *sistrum* in her hand, a musical instrument which the Egyptians used in the worship of the gods. She is often accompanied by her infant son Horus. In one celebrated Egyptian statue she was shown with her face veiled. She was particularly worshipped in Memphis, but at a later period throughout all Egypt. From Egypt her worship passed over to Greece and Rome.

Islam, a term which signifies the Mohammedan religion; complete submission of body and soul to God, His will and His service, as well as faith in all those articles of profession, commands, and ordinances ordained by Mohammed. Every man who makes this profession (*aslama*) is a Moslem, that is, has entirely given himself up to the will of God, and is, on that account, in a state of salvation (*salam*). It is held that Islam was once the universal religion, and that every child born in the true faith would abide in it, without defection, were it not for parental wickedness. As Islam comprehends the practical as well as the doctrinal tenets of the Mohammedan religion—every thing which Moslems must believe and practise—it embraces the whole of their civil and religious polity; for the system of Mohammed relates more to this world than the next, and was designed, like the law of Moses, for the secular as well as the spiritual direction of his followers. But, taken in its more common and direct sense, it signifies the profession of the five fundamental doctrines on which, according to a traditional declaration of the prophet, the whole edifice of the faith is built. Those five points are: (1) The acknowledgment of the Divine Unity and of the prophetic mission of Mohammed; (2) Observation of prayer; (3) Giving of alms; (4) Keeping the fast of Ramadan; and (5) The performance, if possible, of the pilgrimage to Mecca. They are also often subdivided and enlarged, in order to arrange them more conveniently into the two classes of belief (*iman*) and practice (*din*). The former relates to (1) God; (2) the angels; (3) the Sacred Book; (4) the prophets; (5) the last day; and (6) the divine decrees: the latter to (1) purification; (2) prayer; (3) alms; (4) fasting; and (5) the pilgrimage. To the first article of this creed the Persians and other adherents of Ali add, "Ali is the vicar of God"; and that is the only essential point in which they differ from the Sunnites, or orthodox Muslims, who acknowledge the authority of the four first khalifs. The disputes concerning the succession to the khalifate, or supremacy of the prophet, spiritual and civil, which arose immediately after his death, split his followers, as is well known, into two distinct sects, the Sunnites and the Shiites, who have never since ceased to hate each other with a bitter animosity; but they differ more in the degree of veneration paid to Ali than in any other point; and professing the

same creed, with the exception of one article, they derive their doctrines from the same sources. In their respective rituals, and their interpretation of particular texts, there are many minor differences; but both agree in superadding a traditional to the written law of Mohammed, and both have sanctioned that departure from the original simplicity of his doctrine, the re-establishment of which was the professed object of the Wahabees. See MOHAMMED.

Island, a body of land entirely surrounded by water. Islands are of very different extent and surface, and some are so large that authors have doubted whether they should be called continents, as Australia; this, however, is a mere matter of definition. The great masses of land forming the Eastern and Western Continents are in reality islands. The following table shows the relative mainland area of the largest islands:

ISLANDS	Area in sq. m.	ISLANDS	Area in sq. m.
New Guinea	303,000	Iceland	40,300
Borneo	284,000	Mindanao	37,000
Madagascar	227,000	Ireland	32,600
Sumatra	162,000	Haiti	28,800
Honshu	86,500	Tasmania	26,200
Great Britain	83,700	Ceylon	24,700
Celebes	76,500	Nova Zembla — (N. Island)	19,300
New Zealand — (S. Island)	58,500	Tierra del Fuego	18,500
Java	49,000	Nova Zembla — (S. Island)	15,700
Cuba	45,000	Formosa	15,000
New Zealand — (N. Island)	44,500	Hainan	14,000
Newfoundland	40,200	Sicily	9,800
Luzon	40,000	Sardinia	9,000

A cluster of several islands is called an archipelago. The principal clusters in the Atlantic are the West Indies, the Azores, the Canaries, the Hebrides, Orkney, Shetlands, etc. But the great world of islands is in the Pacific, and some modern writers consider them as forming a fifth division of the world, including the Eastern Archipelago, Polynesia, and Australia, to which they have given the name of Oceania. A large island is a continent in miniature, with its chains of mountains, its rivers, lakes, and is often surrounded by a train of islets. The rivers of islands are in general little more than streams or torrents, and the smaller islands are often uninhabitable from want of water; but they serve as haunts and breeding-places of innumerable sea-birds. There are islands in rivers and lakes as well as in the sea. In rivers they are often formed by the division of the stream into various branches, and often by accumulations of earth brought down and deposited around a rocky base. Examples are not wanting of floating islands, which are formed by the roots of plants and trees interlacing with each other, and thus constituting a support for deposits of successive layers of earth. Islands have been grouped into the two distinct classes of continental and pelagic or oceanic islands. Continental islands follow each other in succession along the margin of the continents, and are generally of the same geological structure. Pelagic islands are mostly of volcanic or coral formation. Considerable islands have been known to be suddenly raised up from the sea-bottom by volcanic action, and soon after to have as suddenly disappeared in the ocean. The Pacific contains a great number of low islands having their basis formed of coral reefs, these reefs being produced by the labors

ISLE LA MOTTE—ISLE OF PINES

of innumerable coral-animals or zoophytes. (See CORAL.) Submarine islands, as they have been sometimes called, are immense banks of sand above which there is no great depth of water.

Isle La Motte, Vt., in the northern part of Lake Champlain, the northern point about 8 miles from Rouse's Point, N. Y., on the Canadian border; the southern point about 15 miles north of Plattsburg, N. Y. It is about 7 miles long and 2 miles wide. The island has large marble quarries; some of the stone for Victoria Bridge, Montreal, for Fort Montgomery on Lake Champlain, for the Brooklyn Bridge, and for many other structures and buildings came from those quarries.

This island was a frequent resort for the Algonquin and Iroquois Indians; at the south end was once an Indian village. It was discovered by Samuel de Champlain in July 1609 and was named after a French officer, Sieur La Motte. In 1665 a wooden fort called Fort Sainte Anne was built on the south shore. The 'Jesuit Relations' contain numerous references to Fort Sainte Anne, Isle La Motte, and the visits made to this island by the early missionaries. (The chapel of Sainte Anne, erected near the ruins of Fort Sainte Anne, was consecrated 16 July 1893 by Bishop De Goesbriand of the diocese of Burlington, and it is now a place of pilgrimage.)

On 24 Aug. 1690, Capt. John Schuyler and his company stopped at Fort Sainte Anne on their return from an expedition into Canada. The island was included in the grant made in 1733, by M. de Beauharnois, then governor of Canada, to Sieur Pean, major of the town and castle of Quebec, and in the French seignory granted to Sieur Pedon, councillor in the superior council of Quebec in 1752, notwithstanding the cession of sovereignty to the crown of Great Britain by the French in the Treaty of Utrecht in 1713 over the Five Nations of Indians, who claimed Lake Champlain and the circumjacent territory. In 1775 Philip Schuyler remained on this island over night and joined James Montgomery near there en route for Quebec, where Montgomery lost his life. In the spring of 1776, when Gen. Sullivan withdrew his forces from Canada, the sick were sent to Isle aux Noix, Point au Fer, and Isle La Motte. On 8 Aug. 1776, Benedict Arnold, after engaging the Indians in the British service on 6 August, at the Bouquet River, fell back to Isle La Motte, where his fleet remained anchored until 19 August, when he sailed south toward Cumberland Head.

Isle La Motte was settled in 1785 by Ebenezer Hyde, Enoch Hall, and William Blanchard and was organized as a town in 1790. In 1814 Commodore Macdonough stationed his fleet for a time north of this island and subsequently sailed to the bay near Cumberland Head, N. Y., where he afterward fought the battle of Plattsburg. Soon after Macdonough's departure from the island, in September 1814, Capt. Pring (British) erected a battery on the west shore of the island about a mile and a half south from Fort Sainte Anne and made efforts to win over the inhabitants to the British cause, but failed. On 8 Sept. 1814, he was joined by Capt. Downie and three days later they sailed away to attack the Americans at Plattsburg, where they were repulsed. They returned to Canada, removing

their munitions of war from the island in their retreat.

The first permanent settlers on the island were from New England. One of those sturdy pioneers was Capt. Caleb Hill, who, at the War of 1812, organized his townsmen into a military company which was known as Company F of the 2d brigade of the 3d division of the Vermont militia. After the departure of Macdonough, Capt. Hill's house was entered one night by a squad of British soldiers, and in his efforts to take them prisoners he was killed. The first ferry established from Isle La Motte to Alburgh, Vt., was by Capt. Hill, and the ferry was maintained by his descendants for three quarters of a century, until the construction of a stone bridge connecting the two islands.

There are on the island two public schools, a Methodist church, town-hall, and a government light-house. The light-house has been in charge of Wilbur F. Hill for nearly 30 years. The island is a favorite summer resort. The strangers who visit the island and vicinity are reminded of the words by which the Indians, in 1609, told Samuel de Champlain about picturesque Lake Champlain, that "It was filled with beautiful islands and with a fine country surrounding it."

Island Number 10, a former island in the Mississippi River, near the northwestern corner of Tennessee, and about 40 miles below Columbus, Ky. Since the Civil War it has been washed away. It was the tenth in a succession of islands lying below Cairo, Ill. Early in 1862, having been fortified by the Confederate, Gen. Polk, it was commanded by Gen. Mackall, who had about 7,000 troops of Beauregard's army. It was bombarded for three weeks by Commodore Foote, commanding seven Federal gun-boats, and surrendered 7 April 1862. The evacuation was forced by Pope with a large land force. He, under cover of a vigorous fire from two gunboats, which had run past the island by night, brought his men across the river in transports. The defenders of the batteries fled, and were pursued into the swamps. Over 6,000 prisoners were taken, together with an immense quantity of ammunition and supplies. The Federal forces lost only a few men. Consult the Century Company's 'Battles and Leaders of the Civil War,' Vol. I.

Isle of Man, in the Irish Channel, the largest island in the English seas. The principal towns are Douglas, Castletown, Ramsey, and Peel. Castletown is the ancient capital, but Douglas (pop. 15,719) is the chief town and the seat of government, which is "home rule" under a lieutenant-governor, who, with council and House of Keys of 24 members, makes up the Tynwald Court. The Manx people are a distinct Celtic nationality. Their language and old customs are rapidly disappearing. Area, 220 square miles. Pop. (1900) 55,668.

Isle of Pines (*Isla de Pinos*, *es'lā dā pē'-nōs*), a small island belonging to Cuba, 40 miles southeast of Pinar del Rio. In 1900 the United States gave unofficial expression to the policy of its acquisition as a coaling station. It has an area of about 840 square miles. It is in effect two islands connected by a marsh, the one on the north being somewhat broken by hills, the one on the south low, flat, and sandy. The climate is healthy, the soil fertile and the min-

ISLE ROYALE—ISOLATION

eral resources extensive. For administrative purposes the island is a municipal district of the province of Havana. There are large marble quarries here. Cattle raising is the chief occupation of the inhabitants. Pop. (1900) 3,199.

Isle Royale, *île-rl* (Fr. *île rô-yâl*), an island in Lake Superior, within the state boundary of Michigan. It is 45 miles long, 9 miles wide and has an area of 229 square miles. Valuable deposits are found here.

Isle of Wight, *wit*, the second largest island in the English seas, near the Hampshire coast. It is four miles in breadth, but only a mile in width on the west, between Hurst Castle and Cliff End, while it expands to seven miles between Southsea and the Foreland on the east. In shape the island is an elongated rhomboid. Its extreme length, from the Foreland to the Needles, is about 23 miles, and its extreme breadth, Cowes to St. Catharine's Point, is about 13 miles. The late Queen Victoria had a residence here. The area is calculated at 145 square miles. Pop. (1901) 82,000.

Isles of Shoals, a group of eight barren islands in the Atlantic Ocean, near the New Hampshire coast, 10 miles southeast of Portland, Maine, from which a daily steamer plies during the summer months. The three principal islands are Appledore (400 acres); Star (150 acres), and White (55 acres). There is a revolving government light on the last named, 87 feet above the sea. On Star and Appledore islands are several large hotels for summer visitors who find sea air, boating and fishing here. A few fishermen are numbered among the permanent inhabitants.

Islip, N. Y., town in Suffolk County, on Long Island; on the Long Island railroad, 44 miles east of New York. The town comprises several small villages and covers an area 20 miles long and 10 miles wide. Here are the Manhattan State Hospital for the Insane, Saint Joseph's Convent (Roman Catholic), and a large fish hatchery, owned by the State. The town is popular as a summer resort and has many fine hotels along the shores of Great South Bay. The Fire Island lighthouse, 166 feet high, is located eight miles from the mainland. Blue Point oysters are shipped from the town in large quantities. The government is vested in a town supervisor and town board, elected every two years. Pop. (1900) 12,545.

Isocrates, *i-sôk'ra-têz*, Greek orator: b. Athens 436 B.C.; d. there 338 B.C. His principal teachers were Tisias, Gorgias, Prodicus, and Protagoras. On account of his weak voice and natural timidity he was reluctant to speak in public, but gave lessons in the art of eloquence, and made orations for others. He thus made considerable profit, for he received twenty talents (\$14,375) for a speech that he wrote for Nicocles, king of Cyprus. He was the first who saw the value of oratory in public life. By basing it on sound moral principles he rescued it from the abuses of the Sophists. He was distinguished for a polished style and a harmonious construction of his sentences. The composition, revision, and repeated polishing of his speeches occupied so much time that he published little. His celebrated panegyric on Athens 'Panathenaicus' employed him 10, or according to others, 15 years. As all his speeches were

modeled after the same pattern, their sameness excited weariness, although his subjects were the most important points of morals and politics. His patriotism was sincere, and his desire for the freedom of Greece so intense, that he starved himself to death in his ninety-eighth year from grief at the battle of Cheronea, "fatal to liberty." In Plutarch's time 60 orations went under his name, not half of which were, however, deemed genuine. Twenty-one now remain, of which the principal are the 'Panegyricus' (an oration in which he exhorts the Greeks to concord, and to war against the Persians) and the 'Panathenaicus' (in which he dilates on the services rendered by Athens to Greece).

I"sodimor'phous Series. See ISOMORPHISM.

Isoetales, *i-sô-é-tä'lëz*. See FERNS AND FERN-ALLIES.

Isolation, in evolution (q.v.), the separation or segregation of any set of animals in a particular area, so that incipient varieties or species are prevented from breeding with the parent species of adjoining regions. Through such isolation the swamping or leveling effects of free intercrossing, or mixing with allied varieties or incipient species, are prevented. As a consequence, variations or nascent species become fixed or localized, being prevented from spreading by some geographic or topographic barrier, with the result that there are many thousands of local races, varieties and species; indeed, probably over half of the number of known species are such forms. Not only species, but genera and higher groups are thus isolated. Thus the marsupials of Australia are, with one or two exceptions, confined to that continent, the connection once existing with Asia having been cut off. In one sense natural selection, or the inbreeding of the fittest, is a form of isolation, as also is preferential mating (q.v.) and also those cases when animals breed at slightly different seasons. What Weismann calls Amixia is substantially the prevention of free intercrossing by the geographical isolation of a part of the individuals of a species from their parent stock. Romanes insists that "without isolation, or the prevention of free intercrossing, organic evolution is in no case possible," and he claims that isolation "has been the exclusive means of modification, or more correctly, the universal condition to it."

Examples of Isolation.—These are found among cave animals (q.v.) where animals confined to the nether world, living in total darkness, are prevented from breeding with their ancestors of the upper world. The deep-sea fauna is another such assemblage, living in gloom and in water at the freezing point, although at the surface the winter temperature of the sea may be 80-85° F. Other examples of the result of isolation are the assemblage of animals peculiar to certain islands, to basins walled in by mountain chains, valleys, deserts, and Alpine summits. Interesting cases of isolation on islands are the gigantic moa birds of New Zealand; the local species of birds confined to the different islands of the Galapagos archipelago, also the land shells living in the different valleys of Oahu, one of the Hawaiian Islands.

Another form of isolation Romanes calls "physiological selection," though Seeböhm suggests that physiological isolation would be a better term. The first to call attention to the

ISOMERISM

value of isolation was Lamarck, while Wagner has shown the great value of migration and the intervention of geographical barriers in the formation of species.

Isomerism (Greek, "having equal parts"). Chemists formerly assumed that two bodies must be identical in chemical nature, in all respects, provided they consist of the same elements, combined in the same proportions. This view was long ago found to be untenable, and many substances (mostly compounds of carbon or nitrogen) are now known, which exhibit widely different properties, although possessing the same empirical formula. Bodies which possess this peculiarity are said to be "isomeric" with each other, and the property itself is called "isomerism." In its broadest sense, isomerism may be regarded as embracing (1) polymerism, (2) metamerism, (3) isomerism in the narrower sense, and (4) geometrical isomerism.

Bodies are "polymeric" when they have the same percentage composition, but have different molecular weights. Acetic acid, $C_2H_4O_2$, and grape sugar, $C_6H_{12}O_6$, for example, are polymeric with each other, because they consist of the same elements, combined in the same proportions, and yet the molecular weight of grape sugar is three times as great as that of acetic acid. In this particular case there is no specially close relation between the polymeric substances, and the polymerism is therefore said to be "accidental." When a close relation does exist between the bodies compared, the polymerism is said to be "generic." Ordinary acetic aldehyde affords a good example of generic polymerism. Aldehyde has the formula C_2H_4O , but when treated with a mineral acid it becomes transformed into paraldehyde, which has the formula $C_6H_{12}O_2$; and the reverse transformation (of paraldehyde into aldehyde) may be effected by the application of heat.

Compounds are said to be "metameric" when they have the same empirical formula, but differ structurally by containing different radicals, joined by a polyvalent element such as oxygen, nitrogen, or sulphur. Ethyl ether and propyl-methyl ether, for example, both have the empirical formula $C_4H_{10}O$; but ethyl ether contains two ethyl radicals, united by an oxygen atom, and propyl-methyl ether contains a propyl radical and a methyl radical united by oxygen in the same manner. Thus these two metamerous bodies have the structural formulae $C_2H_5 > O$ and $C_2H_5 > O$, respectively. Metamerism is manifested, most commonly, by the ethers, esters, and amines.

Isomerism in its narrower sense, or "true isomerism," embraces those cases in which the bodies compared have the same empirical formulae, but have different structural formulae, and do not (like metamerous bodies) consist of definite carbon radicals united by oxygen, sulphur, or nitrogen. True isomerism may be of two kinds: (1) "nucleus isomerism," and (2) "isomerism of position." The hydrocarbons afford good examples of both kinds of true isomerism. The paraffin known as propane, for example, has the empirical formula C_3H_8 , and the structural formula $CH_3-CH_2-CH_3$. Propane may be converted into butane by replacing one of its

hydrogen atoms by the methyl radical, CH_3 ; but the substitution may be made in two essentially different ways, according as the hydrogen that is replaced is attached to the interior carbon atom, or to one of the terminal ones. In the latter case the structural formula of the new substance is $CH_3-CH_2-CH_2-CH_3$, and the substance itself is known as "normal" butane. If the hydrogen that is replaced is attached to the interior carbon atom, a different substance, known as "isobutane" and having different properties from normal butane, is formed; its structural formula being

These two substances,—normal butane and isobutane—are said to manifest "nucleus isomerism," since they differ by the mode of arrangement of their fundamental carbon chains. As the number of carbon atoms in a compound increases, the possibilities of nucleus isomerism becomes enormous. Thus the general empirical formula of the saturated fatty hydrocarbons (or paraffins) is C_nH_{2n+2} . We have seen that in the case of butane (for which $n=4$) two nuclear isomers are possible. If the same kind of reasoning is applied to the higher members of the series, regarding each member as derived from the preceding one by the substitution of a methyl radical (CH_3) for a hydrogen atom, we shall find that there are 3 pentanes ($n=5$) possible: 5 hexanes ($n=6$); 9 heptanes ($n=7$); 18 octanes ($n=8$); 35 ennanes ($n=9$); 75 decanes ($n=10$); 159 hendecanes ($n=11$); 355 dodecanes ($n=12$); and no less than 802 tridecanes ($n=13$).

In that kind of true isomerism which is called "isomerism of position," the isomeric bodies contain substituted atoms or radicals, which occupy different positions in the main chain. Thus a paraffin may be converted into an alcohol by substituting a hydroxyl radical (OH) for one of the hydrogen atoms, and the resulting alcohol will have different properties according to the position of the hydrogen atom that was replaced. For example, four butane alcohols are possible. In normal butane, the structural formula of which is given above, the hydroxyl radical may be substituted for one of the terminal hydrogen atoms, in which case an alcohol is obtained which has the structural formula

and is known as "normal primary butyl alcohol." If the hydroxyl is substituted in the place of one of the interior hydrogen atoms, an alcohol is obtained which has the structural formula

and is known as "secondary butyl alcohol."

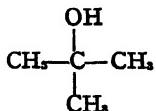

Proceeding, now, to the consideration of isobutane, we note that two essentially different substitutions of the hydroxyl radical are here possible. We may replace a hydrogen atom in one of the three CH_3 groups, or we may replace the one in the CH group. In the first case the alcohol has the structural formula

and is known as "isopropyl butyl alcohol":

ISOMORPHISM—ISTHMIAN CANALS

and in the second case it has the structural formula

and is known as "tertiary butyl alcohol." All of these four alcohols have been actually prepared. (For isomerism of position as manifested in the aromatic compounds, and for the nomenclature used in distinguishing the various isomers that those compounds can exhibit, see AROMATIC COMPOUNDS.)

Certain compounds are known which possess not only the same empirical formula, but the same structural formula also, and yet manifest distinctly different properties, either chemically or physically. Fumaric and maleic acids (see FUMARIC ACID) are examples of this. In such cases the provisional hypothesis is made, that the geometrical structures of the molecules of the two substances are related to one another in something like the same manner that the image of an object in a mirror is related to the object itself, and the isomerism is said to be "geometrical." (See STEREO-CHEMISTRY.)

With reference to isomerism in general, consult Hjelt, 'Principles of General Organic Chemistry'; Lothar Meyer, 'Modern Theories of Chemistry.'

Isomorphism, identity of crystalline form. Isomorphous bodies can form homogeneous mixed crystals; and each one is capable of growing in a saturated solution of the other, fresh crystals being gradually amassed around the original body as a nucleus. Carbonates of calcium, known as calcite; of magnesium, iron, manganese and zinc (magnesite, siderite, rhodochrosite, smithsonite) all are of the same class in crystallography (q.v.). The presence of the same chemical elements of composition in substances does by no means imply isomorphism and substances of very varying components may yet be isomorphous. The isomorphous elements in isomorphous salts, as, for instance, the metals, are generally of the same or related groups of elements. Dimorphous substances, that is, those which form crystals of more than one kind, are often connected by a third dimorphous substance, such as carbonate of lime in the case of calcite and aragonite, and form a group known as isodimorphous substances. See CRYSTALLOGRAPHY.

Isopoda, i-sóp'ō-dá, an extensive and varied group of *Crustacea* (q.v.) usually ranked as a suborder of the *Arthrostraca* or sessile-eyed *Malacostraca*. The body is broad and flattened, and either short or elongated; the carapace is little developed; the thorax long with seven free segments, each bearing a pair of walking limbs; the abdomen more or less shortened and bearing lamellar branchial appendages. The *Isopoda* are classified in seven tribes and more than 30 families, embracing an enormous number of species. They vary greatly in form and mode of life but all are of relatively small size and retiring habits. The vast majority are marine, but a few are inhabitants of fresh water or terrestrial; the latter are familiar to everyone under the names wood-lice and pill-bugs. Most of the marine forms live a free life but conceal themselves in crevices or among

sessile animals and plants, others bore into wood, some, as the gribble and its allies, being destructive to piling; many are commensal or parasitic, among the latter being the *Cymothoidæ*, which infest fishes and whales, and the greatly degenerated *Bopyridæ*, which live in the branchial chamber of prawns and similar crustaceans. The group is traceable in fossil forms as far back as the Upper Carboniferous. Consult Packard, 'Zoology' (1887); 'Richardson, 'Key to Isopods of North America,' in Proceedings United States National Museum, Vols. XXI. and XXIII. (1899, 1901).

Isopondyli, i-sô-spônd'i-li. See ICHTHYVOL-

OGY.

Ispahan, i-s-pä-hän', or *Isfahan*, important city and former capital of Persia, 210 miles south of Teheran, in the midst of an extensive plain watered by a broad river. In the time of Chardin the walls were 24 miles in circuit, and contained 162 mosques, 48 colleges, 1,802 caravansaries, and 273 public baths, and the population was then estimated at 600,000. A great part of the city is at present a mass of ruins. Under the caliphs of Bagdad it became the capital of the province of Irak. Being situated in the centre of the empire, and surrounded by the most fertile territories, it soon became a place of great population, wealth and trade. In 1387 it was taken by Tamerlane and the citizens were given up to indiscriminate massacre, and 70,000 are said to have perished. In 1722 it was taken by the Afghans; but in 1727 it was retaken by Nadir Shah, since which it has not been a royal residence. The great palace built by Shah Abbas is said to have been five miles in circuit, a great part of which space, however, was laid out in ten gardens, adorned with summer houses. The square called Maidan Shah was one third of a mile in length, and was formerly encircled by a canal bordered with plane-trees; but all vestiges of both are now obliterated. The streets are narrow, winding, irregular, unpaved, and very dusty. When Ispahan was in its prosperity its suburbs were distinguished for their extent and beauty. The manufactures of the city are still extensive, including trinkets, fire-arms, sword-blades, glass, and earthenware. The textile fabrics range from the most expensive velvet and satin to the coarsest nankeen and calico. The present population is about 75,000.

Is'rælites. See JEWS and JUDAISM.

Israels, Joseph, yô'séf ez-rä-äls', Dutch painter: b. Groningen 27 June 1824. He was a pupil at Amsterdam of Kruseman and at Paris of Picot, and established his studio first at Amsterdam and later at The Hague. Having essayed historical painting with no marked success, he turned his attention to genre work. He found his subjects among fisherfolk and the humbler classes, whose existence, particularly in its more serious or tragic phases, he depicts in a style likened to that of Millet. Among his canvases are: 'Awaiting the Fishing Boats'; 'Alone in the World'; 'Nothing More'; 'The Struggle for Existence'; 'On the Dunes.' He published 'Spanien, eine Reiseerzählung' (1900). Consult the study by Liebermann (1901).

Isthmian Canals, American. The plan of uniting the Atlantic and Pacific Oceans by a

ISTHMIAN CANALS

great ship canal has been a dream of navigators for several centuries, almost in fact since the days of Columbus, for as early as 1581 the first survey was made to determine the feasibility of connecting the two oceans. In that year, in obedience to instructions, Capt. Antonio Pereira, governor of Costa Rica, organized an expedition and explored a route by way of the San Juan River, the lake, and the rivers emptying into Gulf Nicoya, Costa Rica. In 1620 Diego de Mercado submitted to King Philip of Spain an elaborate report in favor of the construction of a canal over that route which is known as the Nicaragua route. The Panama canal project was conceived later, and other projects were advanced, one of which was the bold conception of James B. Eads, an American engineer, to construct at Tehuantepec a railroad which would be able to carry the largest ships from ocean to ocean. The scheme of connecting the two oceans has possessed a fascination for men of science and an intense interest for men of commerce ever since it was proposed. A number of surveys of the Panama and Nicaragua routes were made during the past half century, but it may be said that not till 1879 was the first positive step taken toward the realization of the project on which so much thought had been expended. In May of that year an International Congress was convened in Paris by M. Ferdinand de Lesseps to discuss the plan of cutting a canal through the Isthmus of Panama. The congress adopted a plan which had been prepared previously by M. de Lesseps, and immediately following that action the Panama Canal Company was formed. The company secured from Lieut. Lucien Napoleon Bonaparte Wyse of the French navy the concession which he had obtained from the United States of Colombia. After the concession had been secured by the company, a commission, known as the De Lesseps Engineering Commission, was sent to Panama to make surveys and prepare estimates of cost. The commission estimated that a canal could be made for \$43,000,000 francs. De Lesseps reduced these figures to 600,000,000 francs, or \$120,000,000, and announced that a *canal à niveau*, or tide level canal, could be completed for that sum. So confident was he of the accuracy of his calculations that he invited men of prominence to attend the opening of the canal, which he set for 1888.

On 21 Feb. 1881 the first detachment of canal employees arrived at Colon. Surveys were made, and the building of camps, hospitals, and other necessary buildings followed. In 1882 the Panama Canal Company purchased the Panama railway. Interest charges accumulated between 1882 and 1888, while nothing like the progress on the canal which had been anticipated had been made. In the autumn of 1888 further borrowing became impossible, and then came a crash which shook the financial world. On 1 Jan. 1889 the company was forced into liquidation. This event created a ferment throughout France, no less than 800,000 French shareholders having been induced to invest in the stock of the company, largely through the appeals which had been made to their patriotism. A receiver was appointed by the Court of the Seine with unlimited powers. In 1890 the receiver sent a commission of French and other engineers to Panama to report on the actual condition of the work. The report was discouraging. Not

more than a fifth of the proposed work had been done; a valuable plant, estimated at \$30,000,000, was rusting away and useless; the tide level at Colon was filling in and the harbor was shallowing, owing to the cut.

In 1891 the government of Colombia granted to the Panama Canal Company an extension of 10 years from 1893 in which to finish the contract, provided operations were resumed before February 1893. In November 1892 a member of the French Chamber of Deputies, M. Delahaye, created a profound sensation in Paris by declaring on the floor of the Chamber that the Panama Canal Company had obtained exceptional privileges, which it had used for the purpose of defrauding investors, by the bribery of no fewer than 100 deputies. The demand for an investigation of the charges was of such force and insistence as to be irresistible, and the ministry decided to submit the whole question to a committee. Following this decision, Baron Reinach, a banker accused of being the instrument or agent of much of the corruption of the company, died suddenly, and it was alleged that he had poisoned himself. Amid a popular clamor, such as Paris had not known for many years, the investigation was carried on, and the disclosures before the investigating committee indicated that the operations of the canal company had been slimed with fraud. It was shown that the Panama Company had bribed deputies and journalists on an extensive scale in order to cover up its shortcomings and leave the way open for further imposition.

In February 1893 M. de Lesseps, his son Charles, and some of their colleagues were sentenced to various terms of imprisonment for fraud and bribery. At the time the blow fell M. de Lesseps had passed his 80th year. Bitter as was the feeling of the French toward those who were responsible for their loss of money, much sympathy was manifested toward the man who had been the presiding genius of the great enterprise. That he had been knowingly a party to the great fraud which had wrecked the hopes and fortunes of so many worthy persons in France, the public was loath to credit. The sympathy for him took such form that he was not imprisoned. But the great engineer, who had reaped so much glory through the construction of the Suez canal, was unable to withstand the blow which the Panama exposure gave him. He died in November of the year following. At the end of 1893 the only prominent person left in prison as the result of the Panama prosecutions was M. Bailhut, formerly Minister of Public Works.

In 1894 a prominent French engineer professed a scheme by which he claimed the work could be completed in four years at an additional cost of \$110,000,000. A new company was formed, and 300,000 shares were issued. Work on the canal was resumed under French auspices. Early in 1895 a strike occurred among the laborers on the canal, and the methods of the new company were criticised severely by the stockholders. Another scandal such as had attended the operations of the original company was feared, but developments showed that the suspicions were unwarranted. Nevertheless, the confidence of the French public in the ultimate success of the enterprise had been shaken to such extent as to make it manifest that the com-

ISTHMIAN CANALS

pletion of the canal under French auspices was no longer a possibility.

That being the situation, those who were bound up in the enterprise turned toward America for relief. The United States up to that time had concerned itself, as far as the building of a canal was considered, solely with the Nicaragua route. The first survey for a canal at Nicaragua under American auspices was made in 1852 by Col. A. W. Childs. The project as outlined by him has been the basis for all subsequent locations. A second survey was made in 1872 by a party under the charge of Commander E. P. Lull of the United States navy. Eleven years later another survey was made by A. G. Menocal, a civil engineer, also of the United States navy. In 1889 the Maritime Canal Company was organized to construct the Nicaragua canal on the lines of the Menocal project. As there was, for a decade following, considerable enthusiasm over the Nicaragua canal scheme in the United States, the project of the Panama Company enlisting American capital, were anything but promising.

Nevertheless an auxiliary American company was organized. In the investigation of the French company's affairs which was made by the new American company, it was ascertained that of the \$156,400,000 expended by the original company only \$88,600,000 had been expended legitimately on the excavation and construction, the rest having gone in bribery and corruption. The second French company was started with a capital of 65,000,000 francs, about one half of which was expended cautiously on construction in four years. The second French company had abandoned the original plan of constructing a tidewater canal. Its plans contemplated the construction of a canal with locks.

The history of the isthmian canal project shows that faith in the Nicaragua route as the most practicable suffered a steady decline. This decline was due more than anything else, perhaps, to the uncertainty of the cost of carrying out the project. The first estimate of the Maritime Company was \$67,000,000. After doing more or less work on the canal the Maritime Company ceased operations in 1893 for lack of funds. In 1895 Congress appointed the Ludlow Commission to examine and report on the Maritime Company's project. This commission placed the cost of the canal's completion at \$133,472,893. The Walker Commission, appointed subsequently, increased the estimate to \$140,000,000.

Up to the outbreak of the Spanish-American war the project of constructing an isthmian canal, while acquiesced in by the general public in the United States, had received ardent advocacy only in quarters where a special study of the subject had been made. But at the commencement of that conflict the people of the United States received an impressive object lesson on the need of a canal. That lesson was the historic trip of the battleship Oregon. With the declaration of hostilities American attention was absorbed by the possibility of the Spanish fleet under Admiral Cervera making a sudden attack on some one of the important cities of the Atlantic coast. At that time the Oregon, a newly constructed battleship, was on the Pacific station. It was considered desirable to have the ship added to the strength of the Atlantic fleet. Orders were sent to her commander, Capt.

Clark, to bring her around Cape Horn, using all speed possible. The American people watched with anxiety the famous voyage. It furnished an argument for the construction of an isthmian canal more effective than a century of discussion.

But coincident with the making up of the American mind that a canal must be built, there came the conflict of opinion as to the choice of routes. Those who were interested in the Panama enterprise were quick to see the opportunity opened to them. When the commission that was appointed by President McKinley in 1899 to examine the American isthmus at every available point in order to determine the most practicable and feasible route for a ship canal went to Paris to examine the plans of the Panama Company, the company, realizing the improbability of its being able to raise sufficient funds in France to carry the enterprise to a successful conclusion, decided to face competition with the Nicaragua project before the Congress of the United States. At a meeting of the directors it was decided to transfer all of the property of the company, its rights and powers, together with those of the American auxiliary company, to a new American company. That company was organized under the laws of the State of New Jersey, with the title of the Panama Canal Company of America. The capital was fixed at \$30,000,000 and the company was authorized to increase the amount if necessary. The arrangement which it made with the French company in taking over its rights, was to pay the shareholders of that company partly in money, but mainly in shares of the American company. The French company retains only an equity in the shape of a lien on a specified percentage of the profits remaining after the payment of all operating expenses and fixed charges and a dividend to the stockholders of the new company. An international commission of French, German, Russian, English, and American engineers, consulted by the French company in drawing up its plans, estimated the cost of completing the Panama canal at \$102,000,000, if the two locks were made of a certain width, and \$125,000,000 if the locks were wider. The extended concession from the Colombian government runs till 31 Oct. 1910, a bonus of \$15,000,000 having been paid to secure the extension.

After the American company was organized and the proposition for a transfer was brought definitely before the French directors, so much opposition was developed to the surrender of an enterprise that had absorbed so much French enthusiasm and entailed such sacrifices on the French people that the directors were unwilling to shoulder the responsibility of carrying out the arrangement, and all resigned. The trustees of the De Lesseps company, in particular, were reluctant to sanction the total transfer of the entire management and control from France to the United States. A new board of directors was chosen, which continued the negotiations with the American company, and the transfer was made. Congress ultimately decided on the Panama canal route as the most feasible and practicable and passed the bill under which President Roosevelt was authorized to acquire the American Panama Canal Company's rights.

The price fixed that the United States government should pay the Panama Canal Company of America for its rights and privileges was \$40,000,000. The cost of the completed canal

ISTHMIAN CANALS

was estimated at \$184,233,358. Thus, the passage of the Act of Congress, approved 28 June 1902, "To provide for the construction of a canal connecting the waters of the Atlantic and Pacific Oceans," was the first decisive action taken by the United States Government to secure an isthmian canal. The second important step was taken 17 March 1903, when the Senate ratified the treaty that had been negotiated with Colombia to secure for our country the concession necessary for the canal's construction and management.

The law of 28 June 1902 authorized the President to buy out the New Panama Canal Company, negotiate a treaty with Colombia for a concession, and proceed by means of a commission with the construction of the Panama Canal. If unable to secure a satisfactory title to the property of the Panama Canal Company, or "to obtain by treaty control of the necessary territory from Colombia," the President was empowered to negotiate with Costa Rica and Nicaragua for a concession, and having secured the privileges desired, to construct the canal by the Nicaragua route. The purchase price to be paid the Panama Canal Company was not to exceed \$40,000,000 (the valuation which the Isthmian Canal Commission had placed on the company's entire assets, including the Panama Railroad), and before paying over the money to the company the President was required to assure himself of the validity of the title to the property to be transferred and to await the exchange of ratifications of a satisfactory treaty with Colombia.

The first duty of the President was to investigate the title held by the Panama Canal Company and to determine whether it was a good one, free of encumbrance, and transferable to the United States. The attorney-general was promptly instructed to make this investigation, and his elaborate opinion, together with the data upon which his opinion was based, was laid before the President 25 Oct. 1902. The subject entrusted to the attorney-general was one of great importance, and his report is fortunately comprehensive, thorough, and entirely convincing.

Before the attorney-general made his inquiry, the validity and transferability of the Panama Canal Company's title had been investigated by the Isthmian Canal Commission and by the Senate committee on Interoceanic Canals. One of the important duties imposed upon the Canal Commission was to "ascertain what rights, privileges and franchises" were held by the Panama Canal Company, and "the cost of purchasing all of the rights," and of placing the canal under the control of the United States. Accordingly, one of the five committees to which the several departments of the commission's investigation were committed was the Committee on Rights, Privileges, and Franchises. The report of the Isthmian Canal Commission contains a full historical and analytical discussion of the subject of concessions. The relations of the original Panama Canal Company to the New Panama Canal Company were set forth, and the opinion expressed that the New Panama Canal Company was able to sell its concession and property to the United States, provided the representative of the rights of the old company, the "liquidator," gave his approval of the sale, and united with the new company in the offer to

sell. Shortly after this report was made the New Panama Canal Company offered to sell out to the United States, and the liquidator gave his consent to the sale. The Commission prepared a supplemental report dealing with this offer, and came to the conclusion that the offer thus made was one that the New Canal Company was competent to make, and that Congress ought to accept.

The chairman and a majority of the Senate committee on Interoceanic Canals disagreed with the conclusions of the commission, but the report of the majority was criticised by the minority members of the committee in an ably written report that supported the conclusions reached by the Canal Commission. The latter was accepted by the Senate.

The treaty granting to the United States the concession and rights necessary for the construction, operation, and control of the Panama Canal was signed by Secretary Hay and the Colombian chargé d'affaires, 22 Jan. 1903, and ratified without change by the United States Senate, 17 March. It is a lengthy treaty, containing 28 articles, but is remarkable for the conciseness and directness with which each provision is stated. The Canal Commission did not consider it necessary for the United States to acquire sovereignty over the territory adjacent to the canal. The desirability of our country's having the sole and undivided ownership and control of the canal when constructed was emphasized, and the recommendation was made that the compensation to be paid by the United States should be definitely fixed either as a single payment or as a predetermined annual payment, or as a combination of these two methods. The treaty authorizes the New Panama Canal Company to sell out to the United States; exempts the Panama Railroad Company from its financial obligation to Colombia, and gives the United States a lease for a period of 100 years, renewable at the option of the United States, of a strip of land 10 kilometres wide across the Isthmus of Panama. The United States not only recognizes the sovereignty of Colombia over this leased strip, but "disavows any intention to impair it in any way whatever, or to increase its territory at the expense of Colombia or of any of the sister republics in Central or South America." The United States secures the right to construct the canal and harbors, to establish free ports at the termini of the canal, to maintain hospitals and drainage and sanitary works along the line of the canal and its dependencies, and to install waterworks and a sewerage system in Colon and Panama, with the authority to "collect equitable water rates during 50 years." Colombia agrees not to cede or lease to any foreign power any territory in the Department of Panama, and the United States guarantees that no country shall be allowed to seize such territory.

It is provided that the canal shall be neutral in perpetuity, in conformity with the treaty of 18 Nov. 1901, between the United States and Great Britain; but the United States secures the right to protect the canal. The new treaty in no wise limits the rights of the United States under the treaty of 1846-8 with New Grenada, by which we guarantee the neutrality of the isthmian transit route and the sovereignty of Colombia.

ISTHMIAN CANALS

The canal is to be a neutral highway for the commerce of the world. The United States has been in favor of the principle of neutrality for more than half a century. The only serious difference of opinion has been in regard to the question whether the principle of neutrality should be enforced by an international agreement, such as the treaty of Constantinople concerning the Suez Canal, or whether the United States should be the sole guarantor of the neutral use of the waterway by the people of all nations. The question has been settled in the best manner. The United States stands responsible for the maintenance of the principle of neutrality, having given a pledge to Great Britain and Colombia.

In the summer of 1903 came the unexpected rejection of the treaty by Colombia, and this put a new phase upon the question. It is possible that this act of Colombia may lead to the reopening of final negotiations with Nicaragua and Costa Rica for the construction of a canal by the Nicaragua route. At least there has been much discussion of the old problem of the two canals. The President is empowered to negotiate with those governments if unable to secure a satisfactory title to the property of the Panama Canal Company. The two routes, Panama and Nicaragua, are both practicable and feasible from an engineering standpoint. In 1903 the 'Scientific American' published a comparison of the two routes. This comparison, based upon the reports of the International Commission on Panama and of the Nicaragua Canal Commission, offers a concise and clear résumé of the question. For the bearing on the question of the successful revolt of Panama from Colombia in November 1903, see PANAMA.

The two canals have certain features in common. In both the greatest problem is the maintenance of the summit level and the control of the flood waters of rivers which are subject to extremely heavy freshets. In both cases the plan determined upon seeks to make the one difficulty cancel the other, the flood waters of the rainy season being stored by the erection of large dams across the course of the rivers, the dams being associated with spill-ways, or waste-weirs, by which the impounded waters may be regulated between predetermined maximum and minimum levels.

Panama.—The route of the Panama Canal extends from the six-fathom line in Colon Harbor on the Atlantic to the six-fathom line off Panama on the Pacific, a distance of 49 miles. The physical difficulties consist of the Culebra cut through the continental divide near the Pacific, and the floods of the Chagres River, which latter flows down from the northeast, intercepts the line of the canal at about its centre, and coincides more or less with the general route of the canal from the point of interception to its Atlantic terminus. The problem is to be solved by cutting a tide-level canal for the first 16 miles from the Atlantic to Bohio, where a dam will be thrown across the Chagres River, the dam to be of sufficient height to form a great lake in the valley of the Chagres, whose maximum elevation will be 90 feet above mean sea-level. Allowing for the greatest possible variation due to continued drought or to heavy freshets, the level of the lake will be maintained between the extremes of 82 feet as a minimum and 90 feet as a maximum level above the sea at mean tide. The surplus waters of the rainy season will be discharged over a weir 2,000 feet in length, which will be built not far from the Bohio dam, the waste waters being conducted to the Atlantic partly by the Chagres River and partly by artificial channel. At Bohio will be located a double-lift lock with a total maximum lift of 90 feet. The line of the canal traverses the Bohio lake thus formed for a distance of about 14 miles, or

until it reaches Obispo, where there will be placed a set of gates 100 feet wide, the purpose of the gates being merely to retain the waters of Lake Bohio should it at any time be desirable to drain off the waters of that portion of the summit level lying beyond the gates. Passing through the gates the canal enters the Culebra section, which consists of a great cut through the continental divide. This section is about eight miles in length, and at the Pacific end of it are the Pedro-Miguel locks. Then follows a level 1.33 miles in length, which leads to the Miraflores locks, by which descent is made to tide-level on the Pacific. From the Miraflores locks to the six-fathom line on the Pacific is a distance of 8.5 miles.

Nicaragua.—Although the route of the Nicaragua Canal is nearly four times as long as that at Panama, the cost of its construction, while greater by about \$6,000,000, is nothing like proportionate to its greater length. Topographically considered, the controlling features at Nicaragua are the existence of a great deep-water lake near the Pacific, and its connection with the Atlantic Ocean by the Rio Grande, a river of considerable size and discharging in the rainy season an enormous volume of water. Starting from Greytown on the Atlantic, the canal will be excavated generally along the edge of the delta formed by the San Juan River until it enters the river channel at a distance of 46 miles from the sea. Three miles further down the river, at Conchuda, it is proposed to build a great dam across the San Juan River, whose crest will be of sufficient height to raise the surface level of the impounded waters to a maximum elevation of 110 feet above mean sea-level. The difference of level will be overcome by four locks at various points on this section. This dam will have the effect of canalizing the San Juan River from this point to its point of outflow from Lake Nicaragua, a distance of 49.64 miles. Where the sharper bends of the river occur, cut-offs will be made. The distance across Lake Nicaragua, 70.51 miles, will lie chiefly in deep water; but the approach to the canal at each side of the lake will have to be dredged to obtain the necessary depth of 35 feet. The remaining 17.34 miles of canal from the western shore of the lake to deep water on the Pacific will contain four locks, by which the difference of elevation of 110 feet will be overcome.

SUMMIT LEVEL.

Panama.—The average summit level proposed by the Isthmian Canal Commission for Panama is 85 feet above mean tide. This is to be secured by the construction of a dam at Bohio and a spillway near by, at Gigante, which will be a fixed weir 2,000 feet in length. As a provision against seasons of extreme drought the canal will be excavated to such a depth that the summit level might fall to 82 feet and still leave the requisite depth of 35 feet throughout this section of the canal. The records of the Canal Company and of the Isthmian Canal Commission show that it is improbable these extremes will be reached, or that, if reached, it will be only at very rare intervals.

Nicaragua.—The regulation of the summit level at Nicaragua is a much more serious problem, for the reason that it involves maintaining the level of the extensive Nicaragua Lake, which has an area of between 2,700 and 3,000 square miles, within certain predetermined maximum and minimum levels. It involves, says the report of the Commission, the control of the lake level within such limits "as will never permit the navigable depth of the summit level to be anywhere less than 35 feet on the one hand, nor permit the lake to rise materially beyond a determined elevation on the other. This regulation can be accomplished by the construction of dams across the Rio Grande west of the lake and across the San Juan on the east side, both being designed with suitable water-ways for the discharge of surplus water." The minimum elevation has been fixed at 104 and the maximum at 110. The problem is a stupendous one, and limitations of space prevent any detailed discussion of it here.

DAMS.

Panama.—The Bohio dam is the most important structure on the line of the Panama Canal. The dam proposed by the Panama Company was to have been of clay founded upon a variety of material—hard clay, soft clay, sand, gravel, etc. The Isthmian Canal Commission very wisely decided that for a work of this importance security was a prime object to be aimed at. They decided that a masonry dam founded throughout on rock, or an earth dam with a masonry core going down everywhere to rock, would close the valley effectively and prevent all possibility of seepage. The core-wall-and-earth dam was preferred. The structure, which is to be 2,440 feet in length along its crest, will contain a core wall which will be carried down everywhere to

ISTHMIAN GAMES — ISTLE

rock, the latter being reached in places at a depth of 128 feet below the sea-level. Below elevation—the pneumatic process will be used in construction, and above—30 cofferdams will be used. The cost of this dam will be \$6,369,640, and as it will probably take ten years to build, it will be the controlling feature in the question of time of construction of the canal. Once built, however, it will be a perfectly secure structure for all time.

Nicaragua.—The dam designed by the Commission at Conchuda on the San Juan will be a smaller structure, and the greatest depth to rock will be only 80 feet. The regulation of the surface level will be accomplished by wasteways, vertically-moving gates of the Stoney type being adopted, each giving an opening of 30 feet on the crest of the dam. This discharge will amount to 100,000 cubic feet per second with the water in the pool immediately above it at 104'. The total length of the dam, which will be entirely of masonry, will be 1,271 feet and its cost \$4,000,000.

LOCKS.

Panama.—At Panama there will be but three locks in all, one set at Bohio, with a double lift of a maximum of 45 feet each and a total lift of 90 feet, and two sets at the Pacific end of the summit level—double-lift locks at the Pedro-Miguel and single-lift locks at Miraflores. All of these locks will be on a rock foundation.

Nicaragua.—The ascent or descent from maximum summit level at Nicaragua will be accomplished by eight locks, four on the Pacific side and four on the Atlantic side.

LENGTH AND CURVATURE.

Panama.—The total length of Panama from ocean to ocean is 49 miles, and of this total 22.85 miles is curvature, the total degrees of curvature being 771. The curves are of very large radius and will present no difficulties in the way of navigation, a fact which is commented upon favorably by the Commission.

Nicaragua.—The total length of Nicaragua from ocean to ocean is 186.5 miles, and of this 49.29 miles is in curvature, the total amount of curvature being 2,339 degrees. The greater part of this curvature occurs in the valley of the San Juan River, and owing to the limits imposed by the configuration of the valley, most of the curves are extremely sharp, and must necessarily somewhat hamper navigation, particularly in the case of modern vessels of 600 or 700 feet length. An attempt is made to offset this by providing greater width in the canal on curves. There is no point, unless it be that of shortness in time of transit, in which Panama shows its great engineering and operating advantages over Nicaragua so much as in this matter of alignment.

HARBORS.

Panama.—The Panama Canal is greatly favored in the matter of harbors, which, by the way, are a most essential feature in the successful operation of a maritime canal. Good harbors exist both at Colon and Panama, and with the improvements suggested by the Commission, they will be able to accommodate the largest shipping that seeks the canal.

Nicaragua.—In the matter of terminal harbors, it must be confessed that the Nicaragua scheme is altogether wanting, since they simply do not exist. In 1832 there was a spacious harbor at Greytown with depths of from 18 to 30 feet of water. To-day three-fourths of this harbor is a sandy swamp, and the rest of it is a shallow lagoon with from 6 to 16 feet depth of water. An artificial harbor will have to be constructed both here and at Brito on the Pacific, and the cost of dredging to keep these harbors open will be a permanent charge upon the canal.

TIME OF TRANSIT.

It has been estimated by the Commission that a 400-foot ship would take 11 hours 14 minutes to pass through the Panama Canal, this estimate being based on a speed that varies from 7 miles an hour on curves to 10 miles an hour in Lake Bohio. It is estimated that the same vessel will take 33 hours to pass through the Nicaragua Canal. Suppose that two identical passenger steamers of 18 knots sea speed enter the Atlantic termini at Panama and Nicaragua at 12 o'clock noon, January 1. By the time, 33 hours later, that the steamer at Nicaragua was at the Pacific, the steamer at Panama would be 378 knots distant on the Pacific. This gain, however, would be offset by the saving in distance and time between some of the ports on the Atlantic and on the Pacific.

WORK DONE.

The Commission estimates the value of the work done at Panama, the Panama Railroad, the maps, draw-

ings, etc., at \$40,000,000, while it states that "practically none of the property" representing work done, etc., at Nicaragua "would have any value to-day in the construction of the canal."

COST.

The total cost of completing Panama is estimated at \$144,233,358, while the total cost of building Nicaragua will be \$189,864,062. The Panama Company, however, have offered to sell their properties at the price named by our Commission, \$40,000,000, thus making the cost of the completed Panama Canal \$184,233,358. This renders the completed Panama Canal cheaper by \$5,630,704 at first cost. The Commission, however, say it will cost \$1,300,000 more every year to maintain and operate Nicaragua than it will Panama. This sum capitalized at 4 per cent and added to the cost of constructing Nicaragua, makes the Panama Canal considered as a financial proposition, over \$38,000,000 cheaper in the long run than the Nicaragua Canal.

Isthmian Games, so called because they were celebrated on the Isthmus of Corinth. Here was a famous temple consecrated to Poseidon, near which the Isthmian games were celebrated. On one side of the temple were the statues of the victors in these games, and on the other was a grove of pines. In the temple stood four horses, gilded all over, with the exception of their ivory hoofs: by the side of the horses were two Tritons, the upper parts of which were gilt, and the rest of ivory. Behind the horses was a car, with the statues of Poseidon and Amphitrite, of gold and ivory. Not far from the temple were a considerable theatre, and the stadium, of white stone, in which the games were celebrated. The whole isthmus was sacred to Poseidon, who was thence called *Isthmius*. According to the common opinion the Isthmian games were founded in honor of Palmon or Melicertes, by Sisyphus, king of Corinth. When there was war between the states of Corinth and Athens a sacred truce was concluded, and the Athenians were solemnly invited to attend the celebration of the games. They were celebrated with the same splendor as the Olympian and other public games, in the first and third years of each Olympiad, probably in autumn; the athletic exercises were the same. The victors were at first adorned with wreaths of pine-leaves, but afterward with wreaths of dry and faded ivy. The pine wreaths were afterward resumed. Victory shed a lustre not only over the individual, but over his family and the community to which he belonged.

Istle, is'tl, or Tampico. This structural fibre is produced from several species of small agaves in Mexico, chiefly *Agave heteracantha*, and *A. lechuguilla*. The plants grow wild over a wide area of central and northern Mexico, the centres of the industry being located in the states of Coahuila, Tamaulipas, Nuevo Leon and San Luis Potosi. The fibre is extracted by the peons by hand labor and prepared by rudest methods. The filaments are harsh and stiff, but smooth, and in color a yellowish white, and form an admirable substitute for animal bristles in brush manufacture. Nearly 8,000 tons of the fibre is imported into the United States annually, worth almost half a million dollars. In Mexico the fibre is used for rough cordage and webbing (for saddle girths), and for sacks for the transportation of all kinds of merchandise. A little fibre finds its way into this country to mix with the cheaper cordage fibres, but it cannot amount to very much in the figures of imports. The fibre is derived from the cogolla, or central spike of unopened leaves, these being

ITACOLUMITE—ITALY

separated by hand and each leaf scraped on both sides with a kind of dull edged knife, in order to release the fibre, which lies just under the epidermis. After drying, the fibre is sold at the haciendas, put up in bundles of about 75 pounds, and transported on the backs of pack animals to the neighboring towns, where it is sorted, baled, and sent by rail to the port of Tampico for shipment, hence the commercial name Tampico. For further information see article on Iotle Fibre in Mexico, Scientific American Supplement, (1902). See CORDAGE: CORDAGE INDUSTRIES: FIBRE; MEXICO.

CHAS. RICHARDS DODGE.

Itacolumite, i-tä-köl'-ü-mit, also known as flexible sandstone, is a mineral curiosity. It is a light colored, laminated-granular quartzite containing besides quartz grains, mica, talc and chlorite. Usually thin bedded, pieces an inch thick or more have considerable flexibility. This property is attributed to the presence of thin laminae of mica, talc, etc. and also to the shape of the sand grains which have interlocking angles, due to a secondary growth of the grains by deposition of silica. Itacolumite is found in Brazil, also at several localities in the southern Appalachians.

Itagaki, Taisuke, ti-soo'kä ē-tä-gä'kë, COUNT, Japanese statesman: b. Tosa province, island of Shikoku, 1838. He received a military education, and in the war of the Restoration (1868) was prominent in the imperial army. From 1871 until his resignation in 1873 he was a privy councillor to the emperor. He then became the centre of a movement for constitutional government which in 1877 addressed to the government a memorial asking for a representative assembly and broaching popular rights. Itagaki aimed at a system based on that of Great Britain or the United States, as opposed to the system based on that of Germany, drafted by the Marquis Ito and promulgated in 1890. But he would have been satisfied at first, it is said, with an assembly which quite excluded the popular element. He organized the *Jiyuto*, or Liberals, the first Japanese political party, which rapidly increased in numbers. In 1878 he became minister of public works, in 1880 minister of the interior, and in 1898 the Liberals united with the Progressists, led by Count Okuma, to form the so-called Constitutional party, which had a large majority in the lower house of Parliament. At the Mikado's request Itagaki and Okuma formed a cabinet, with Itagaki as minister of the interior. The cabinet resigned after six months, and the Constitutional party was separated into its original parts.

Italian Architecture. See ARCHITECTURE: ITALY.

Italic Languages, the languages of ancient Italy, before it had become Latinized by the predominance of Rome. These are generally described as Umbrian, Oscan, Etruscan, and Latin. The three first only survive in some fragments and inscriptions. Thus the Eugubine Tables, seven tablets of brass discovered in 1444 near Eugubium, are engraved with a series of sacerdotal inscriptions in ancient Umbrian. Taken together they contain about 450 lines, reading from left to right, some in Roman, others in Etruscan letters. The most important

fragment of the Oscan language is that inscribed on a bronze tablet discovered in 1793, and called the Bantia Table, from the neighboring city of Bantia. The Oscan Bantine inscription contains 36 lines, and is much more easy to interpret than the Eugubine Tables. The Oscan language was spoken in the south of Italy. Another important monument of Oscan is the Cippus Abellanus discovered in 1685. The bronze tablet of Agnone discovered in 1848 also contains an Oscan inscription. The Etruscan language is most difficult of all to interpret. The most important remains which are known were discovered in the neighborhood of Perugia in the year 1822. The inscription is engraved on two sides of a block of stone, and consists of forty-five lines. The learned are divided about its interpretation. The most copious and important of the legal fragments which exhibit the Latin language in its earliest form are the Twelve Tables (q.v.).

Italy, a kingdom in southern Europe, consisting in the main of a large peninsula stretching southwards between the Adriatic Sea and the western part of the Mediterranean, but also including a considerable portion of the mainland and some of the adjacent islands. It is bounded on the north by the Alps, which separate it from Austria and Switzerland, except at the district lying to the north of Lake Garda, where its frontier does not follow the line of the Alps; on the west by France, from which it is separated along the larger part of the frontier line by the Graian, Cottian, and part of the Maritime Alps, and by the Mediterranean; on the south by the Gulf of Taranto and the Mediterranean; and on the east by the Adriatic and a portion of the Austro-Hungarian Empire. It is comprised between lat. 36° 40' and 46° 40' N. and between lon. 6° 35' and 18° 35' E.

Political Divisions.—For administrative purposes Italy is divided into 69 provinces, which are grouped under 16 departments (*compartimenti territoriali*), some of which consist of only a single province. The provinces are subdivided into circles (in Venetia and the province of Mantua called districts). The following table furnishes a list of the provinces and departments, with the area of each, and the population as estimated 1 Feb. 1901:

PROVINCES AND DEPARTMENTS	Area in sq. m.	Pop. on Feb. 1, 1901

KINGDOM OF ITALY	110,646	32,475,253

The principal islands belonging to Italy are Sicily and Sardinia; the others include the Lipari Islands, Capri, Ischia, Giglio, Monte Cristo, Elba, etc. Rome is the capital.

Physical Features.—The length of the coast of the mainland of Italy has been estimated at about 1,450 miles, that of the islands of Sicily and Sardinia at about 850 miles; so that the whole coast-line, inclusive of the smaller islands, must amount to about 2,400 miles. It is not much broken. The whole shore of the Adri-

atic presents a comparatively smooth and continuous line, interrupted only by the spur of Gargano, which, by its south side, contributes to form the Gulf of Manfredonia. The largest gulf of all is that of Taranto, in the south. The west coast, though much more indented than the east, is more remarkable for the number, and occasionally for the beauty, of its bays, than for their magnitude. Commencing at the south extremity and proceeding north, the most important which present themselves, in succession, are those of St. Eufemia, Policastro, Salerno, Naples, Gaeta, and Genoa. The eastern shore is generally flat and uninteresting, presenting, particularly along its northern part, a long series of sandy islands and lagoons, which retard the progress of the rivers, dam up their mouths, and, depriving them of a proper outlet, occasion the formation of pestilential marshes. On the west coast the same thing is occasionally seen, but occurs on a large scale only in the Roman territory, where the Pontine Marshes, notwithstanding the proved practicability of draining them, are permitted to spread their poisonous malaria, and convert extensive tracts, of great natural fertility, into almost uninhabitable deserts. But with this very prominent exception, the west coast is considerably elevated, the ramifications of the mountains often stretching down and terminating in lofty cliffs, with a magnificent background of alpine heights. Few countries can boast of possessing scenery of this description equal to that which is exhibited by the Gulfs of Genoa and Naples.

The interior of Italy is finely diversified. The loftiest mountains of the Alps stand on its northern and northwestern frontiers, and shelter it from the rigors of the north, giving here a climate which is unrivaled for the general mildness of its temperature and the brightness of its sky. In immediate connection with the branch of the Alps called the Maritime Alps is the chain of the Apennines, which, first proceeding east till the Adriatic is approached, then turn south, and run down the middle of the peninsula through its whole length to the Straits of Messina; while numerous branches are thrown off laterally, and form an endless succession either of loftier hills clothed with forests, or gentler slopes covered with olives and vines. In the spaces between the mountains and hills lie valleys remarkable either for their wild romantic beauties or the fertility of their soil. In the north, enclosed between the ranges of the Alps and Apennines, is a plain of vast extent, stretching from the western frontiers of Piedmont, across Lombardy, to the shores of the Adriatic, and perhaps the most fertile in Europe. other plains, still more attractive by their beauty, occur in various parts of the Italian peninsula.

Hydrography.—The Po is the only river of magnitude. It has the advantage of pursuing its course between the Alps and the Apennines, and deriving its supplies from both of them, conveyed from the Alps by the Dora Riparia, Dora Baltea, Sesia, Ticino, Adda, Oglio, and other tributaries on the left bank of the river, and by the Stura on its right bank; and from the Apennines by the Trebbia, Secchia, Panaro, etc., all on its right bank. Another river of some importance, which has its mouth at no great distance from the former, and is partly fed in the same way, is the Adige (*Etsch* in Austria); and the Bacchiglione, Brenta, Piave,

ITALY

Livenza, and Tagliamento, which are of much less importance, have their basins in Venetia or the northeastern part of Italy, and all fall, like the Po and the Adige, into the Gulf of Venice. In the southern part of Italy, the peninsula of which it consists is not only narrow in itself, but is divided by the central chain of the Apennines into two watersheds, each of which lies so near the shore as to leave no room for the formation of large rivers. If the streams descend directly from the mountains to the shore, their course is necessarily so short as to give the character of mere torrents, often rising suddenly in their beds, and again as suddenly retiring within them. It sometimes happens, however, that the mountains, in ramifying, form parallel ridges, and thus give rise to longitudinal valleys, by pursuing which the course of the rivers is greatly lengthened, and their volume of course augmented. In this way the Italian peninsula, notwithstanding its narrowness, has obtained the Arno, Tiber, Garigliano, and Volturno. Numerous lakes are scattered over the surface. Many of them, independent of their natural beauties, derive much adventitious interest from classical associations; the most important are Lakes Maggiore, Como, and Garda.

Geology and Soils.—The general fertility of Italy is intimately connected with its geological structure. Except in the ranges of the Alps in the north, and the terminating branches of the Apennines in the south, granite and the metamorphic strata, which generally form soils of little natural fertility, are not of frequent occurrence, and occupy a very limited extent of surface. On the other hand, volcanic rocks, as might be expected in a country whose volcanic agency is still active, occupy considerable tracts, particularly on the west coasts of Naples and of the Roman territory, where, by their decomposing lavas, soils of almost exhaustless fertility have been formed. The sedimentary rocks of the Italian continent, with exception of the metamorphic strata already referred to, are comparatively recent. At the bottom of the series is the Jura limestone, which is largely developed in the Apennines. The main body of it, commencing on the eastern frontiers of Tuscany, is continued in a broad zone far south into the old kingdom of Naples, where, after a partial interruption, it reappears in the southwest, chiefly in the province of Salerno, and partly in that of Potenza, and in the southeast in the province of Bari. It also occupies a considerable space on the north side of the Gulf of Gaeta, and on the western slope of Mount Gargano. It is likewise the prevailing rock in the north of Lombardy, where it stretches east from the shore of Lake Maggiore to the Austrian province of Illyria. Above the Jurassic limestone, and occupying almost an equal extent of surface, is the chalk, with its accompanying rocks. The main body of it stretches east along the Gulf of Genoa, and north into Emilia, then turns southward through Tuscany, forms a long narrow belt along the eastern side of the main body of the Jurassic limestone, and, though partially interrupted, finally reaches the extremity of the peninsula, where, in Cape St. Maria di Leuca, its white cliffs form the eastern entrance of the Gulf of Taranto. In the north of Naples a large tract, of a somewhat oval form, lies completely enclosed by the Jura limestone. The next strata in the ascending series

belong to the Tertiary period, and consist of sandstones, travertin, and marl. These rocks occupy a considerable portion of Tuscany, and of the central part of Piedmont between Turin and Alessandria, but receive their chief development on the east coast, where, without attaining much width, they stretch without interruption from the neighborhood of Rimini to the northwest extremity of the spur. Here the main body, spreading out, is continued south-southeast, and forms the greater part of the shore of the Gulf of Taranto. Another branch, still skirting the east coast, reaches its extremity in the Gulf of Taranto. Above all the ancient strata now mentioned are immense diluvial and alluvial deposits, still in course of gradual augmentation. Of these partial tracts are found both on the coast of Tuscany and the maritime provinces on the west near Rome, particularly the Pontine Marshes; but they are insignificant in comparison with the space which they occupy in the luxuriant plains of Lombardy, not only forming extensive flats along the northern shores of the Adriatic from the Gulf of Trieste to the Gulf of Venice, but filling the greater part of the basin of the Po.

Mineral Resources.—The chief minerals are sulphur, zinc, lead, copper, coal, iron, antimony, gold, mercury, manganese, silver, arsenic, salt, graphite, borax, petroleum and asphalt. The chief sulphur mines are in Sicily; Elba is noted for the quality of its iron ore, and Lombardy and Sardinia for their zinc ore. In 1901 there were over 1,100 productive mines of various minerals, employing 68,000 workers, with a total output valued at nearly \$17,000,000.

Climate.—The peninsula in its southern part has the dry and burning climate of Africa, as well as the sirocco, which blows on its coasts, and resembles the simoom of that continent. In the continental part of the country the neighborhood of the Alps, the abundance of water-courses, and the direction of the fine valley which opens on the Adriatic are all circumstances which serve to maintain a delightful temperature. Yet this region is at times extremely cold. The climate of Italy generally is salubrious, but there are numerous exceptions to this character. In the north the lagoons and the rice-plantations of the basin of the Po give rise to exhalations which engender fevers. In central Italy the Maremma of Tuscany, the Campagna of Rome, the Pontine Marshes, and the environs of Volturno, produce miasma which infect the air especially during the night.

Forestry.—The sweet chestnut constitutes the larger part of the forests that cover the lower slopes of the Alps and the Apennines, while pine, fir, poplar, myrtle, and other evergreens, clothe the hills of a considerable portion of rest of the country. There is a governmental department of forestry directed by the ministry of agriculture, industry and commerce, through a forestry council. Exclusive of chestnut plantations, the forest area is over 10,000,000 acres producing lumber, firewood, charcoal, and secondary produce to the annual value of over \$17,600,000.

Flora.—The natural productions of the soil of Italy are as various as its climate. In the Alpine regions all the plants belonging to cold climates flourish, while the southern regions possess a real tropical flora. The olive, mulberry, fig, orange, citron, pomegranate, pistachio, jujube, and date grow in the south and in suit-

ITALY

able places in the north. In the extreme south the cotton-plant, sugarcane, Indian fig, agave, and other tropical plants are cultivated. Everywhere is seen the grapevine. The other vegetable products are common to Italy and the rest of Europe.

Fauna.—The fauna of Italy differs little from that of the other countries of Europe situated in the same latitude. Its mountains afford a retreat to the lynx, chamois, brown bear, and wolf, while among those of Sardinia is found the mouflon or wild sheep. The porcupine is very generally found in the Apennines. The pale-red fox (different from the common species) and the blind mole are also found. The birds, which are very numerous, comprise most of the species of Central Europe, a large number of those belonging to the eastern part of Europe, and some African birds, especially the Egyptian vulture. Among the reptiles are the common viper and the asp; other noxious creatures are the scorpion and the tarantula. The marine fauna of Italy is also very comprehensive, including all the varieties of fish which are found in the Mediterranean. The fisheries embrace anchovies, sardines, tunnies, sword-fish, etc. The coral polyp (among other species the madrepore) is also of economic importance, there being a large number of persons employed in the coral fishery.

Land Tenure.—There are three systems of land tenure; that of peasant proprietorship which exists throughout Italy, but chiefly in Piedmont and Liguria; the rent system common in Lombardy and Venetia; and the partnership system, general in Tuscany, the Marches and Umbria, slightly in Sardinia, Calabria, and Apulia, but abandoned in Barese and the province of Naples. The latter system consists in a form of partnership between the proprietor and the cultivator, profits and losses being equally divided, and the families of the partners subsisting in many cases entirely on the common produce of the cultivation.

Agriculture forms the chief support of the population, and the land is very productive in almost all parts of the kingdom, although it is not everywhere equally well cultivated. The best cultivation, aided by an excellent system of irrigation, is found in Lombardy, Venetia, Piedmont, Tuscany, and the parts of Emilia adjoining the Po. The most neglected parts of the country in point of cultivation are the islands of Sicily and Sardinia. About 85 per cent of the surface of Italy is productive, and 15 per cent unproductive. Of the productive land again about 41 per cent consists of arable land and vineyards, 21 per cent of meadows and pastures, 5 per cent of olive and chestnut plantations, and 18 per cent of forests. Italy may be divided into four agricultural zones or regions:—(1) the olive, orange, and citron region, embracing Sicily and Sardinia, the Neapolitan provinces except the Abruzzi, and the part of the coast of Liguria called Riviera di Ponente; (2) the region of olives and pines, embracing the Abruzzi, Umbria, Tuscany, and the part of the Ligurian coast called Riviera di Levante; (3) the vine and oak region, embracing Lombardy, Venetia except the province of Udine, the provinces of Parma, Piacenza, Modena, Novara, Alessandria, and Lomellina, now part of the province of Pavia; (4) the vine and chestnut region, comprising the two large Piedmontese provinces of Turin and Cuneo, and

the province of Udine in Venetia. All kinds of cereals are cultivated. The wheat is of fine quality, and is chiefly used as a breadstuff by the wealthier classes, while maize and rye are principally used by the poor, who also consume great quantities of pulse and chestnuts. Among plants used in commerce and manufacture the following are grown: hemp and madder, which are articles of export, flax, tobacco, hops, and rape in small quantities, saffron, cotton (in the level districts of the province of Salerno, and of Calabria, Sicily, and Sardinia), and sugarcane in Sicily and Sardinia. The commoner kinds of fruit-trees are the objects of attention everywhere, and the cultivation of southern fruits is carried on particularly in the Neapolitan and Sicilian provinces, and in Sardinia, and furnishes large quantities for export. Chestnuts are frequently used as a substitute for bread. In the cultivation of the olive Italy surpasses all other European states; so that, although the home consumption of olive-oil is very large, there remains a considerable quantity for exportation. There is also a very large production of wine. The average annual production of some of the above-mentioned objects of cultivation may be estimated as follows:

Wheat	143,400,000	bushels.
Maize	85,600,000	"
Oats	19,360,000	"
Rye and barley	18,400,000	"
Rice	26,800,000	"
Other cereals	18,000,000	"
 Total cereals	311,560,000	"
Potatoes	19,360,000	bushels.
Hemp	111,000,000	lbs.
Flax	30,000,000	"
Cotton	22,000,000	"
Tobacco	7,250,000	"
Olive-oil	74,500,000	gals.
Wine	666,000,000	"

Italy anciently was celebrated for its wines, the best of which were obtained from the vineyards on the two slopes of the Apennines. Among the most celebrated were those of Liguria, Albanum (now Albano), near Rome, which received the warmest praises from ancient writers; those of Nomentum (Mentana), about 15 miles to the east of Rome, which are compared by Strabo to the best wines of Greece; those of Setia (Sezze), about 35 miles to the southeast of Rome, which were much prized by Augustus and all the wealthy Romans of his age; the Cæcuban wine, which grew in Campania, the province to the south of Latium, and which from the earliest times held the first place among the wines of Italy, and was particularly esteemed for the exquisite delicacy of its flavor; the Falernian and Massic wines, which also grew in Campania, and likewise had a high reputation; and the Mamertine wine from the neighborhood of Messana in Sicily. The southwest of Sicily, which now produces excellent wines, is nowhere mentioned for its wine-growing qualities in the writings of the ancients. At the present day the wines of Italy are admittedly inferior to their ancient reputation. The vines yield many wines, among which the liqueur wines are distinguished for their good quality; but those which serve for daily use cannot enter into competition with those of France. The most of them are at once sweet and harsh, often coarse, and although they appear to combine much body and strength they do not easily bear transport, and deteriorate in little time, even

ITALY

without being removed to a distance. Their bad quality proceeds not only from the want of care shown in the cultivation of the vines, but also from the bad processes employed in the manufacture. Among the liqueur wines which are so abundant in Italy may be mentioned the lacryma-Christi, nasco, giro, tinto, Malmsey, aleatico, and muscat. The most famous of the Italian red wines are those of Carmignano in Tuscany, and those of the Isle of Elba, Bari, and Ischia. The white wines of Marsala and Castel-Veterano are compared to Madeiras of the second class.

Stock-raising.—The rearing of live-stock is an important industry in Italy, which exports cattle, sheep, goats, and swine. Horses are imported, and also sheep's wool. The cultivation of green crops as food for cattle is scarcely known. During the summer the animals are led to the pastures, and in winter they are furnished with straw and a little hay in their stalls. The farmers do not give much attention to the improvement of their domestic animals, which have lost much of their original excellence. The cattle are estimated to number about 5,000,000 (including 15,000 buffaloes), many of them team oxen. Sheep number 6,900,000. Some camels are perfectly acclimated near Pisa in the low-lying tracts of San Rossore. The cheese of Italy is famous, especially the Parmesan.

Commerce.—The foreign trade of Italy is not large in proportion to the size and population of the country, and does not make much progress. In 1882, 1889 and 1900 the imports and exports reached the following figures:

	1882	1889	1900
Imports.....	\$269,080,000	\$277,230,000	\$341,295,925
Exports.....	231,160,000	190,130,000	270,979,920

Among the chief imports are coal, grain, cotton, silk, wool, sugar, coffee; by far the largest export is silk, raw and thrown, others being wine, olive-oil, oranges and lemons, hemp and flax, sulphur. In 1901 the import of coal reached the value of \$30,001,763; of raw cotton, \$31,618,501; cotton goods, \$1,918,296; of silk, raw, twisted, etc., \$14,766,680; of machinery, \$14,521,488. In the same year the exports of silk and silk goods were valued at \$86,272,986 (as against \$101,764,494 in 1899); of animals and animal products at \$10,504,021; of wine in casks at \$7,405,762; olive-oil, \$9,130,994; fruit, \$10,710,753. The trade of Italy is chiefly with France, the United Kingdom, the United States, Germany, Austria, Switzerland, and Russia, the United Kingdom sending in 21 per cent of the imports, and the United States being second with 13 per cent.

In the foreign trade of the United States, Italy occupies the eighth place in exports, and the tenth place in imports, the largest items of import being raw silk, sulphur, and lemons.

Manufactures.—Since the consolidation of the Italian kingdom the manufactures of the country have made considerable advances, especially in the department of Tuscany and the northern provinces. They now afford support to 13 per cent of the whole population. Machine-making, although not sufficing to meet the internal wants of the country, nevertheless employs many workmen, especially in Genoa and neighborhood, Turin, Milan, and Naples. Coach and carriage making is an important industry in Milan. Ship-building is largely carried on in

Liguria. Musical instruments are made in all the capitals. Especially famous are the bow instruments of Cremona, and nowhere are violin strings made so well as in the Abruzzi. In the iron industry the department of Lombardy stands at the head; and in that department more particularly the provinces of Brescia, Como, and Milan. The town of Brescia is the chief seat of the cutlery manufactures. The manufacture of gold and silver wares is very flourishing in Rome, Milan, Naples, Genoa, Venice, and Catania, and like that of articles in bronze has long been an important branch of Italian manufacturing industry. Italy is very rich in marble of the most beautiful and various colors and markings. The department most celebrated in this respect is Tuscany, especially the province of Massa e Carrara, and the district of Serravezza in the province of Lucca. The district of Volterra in the province of Pisa is noted for its alabaster quarries and the making of articles in alabaster. The cities of Rome, Naples, and Florence enjoy a world-wide reputation for their cameos and mosaics, as also (along with Leghorn and Genoa) for articles of coral. Earthenware manufactures have long been carried on in Italy with the best success. The articles in terra-cotta especially are remarkable for the beauty of their forms. Venice and the neighboring island of Murano are celebrated for the manufacture of glass beads, but the other glass manufactures of Italy do not nearly suffice for the home consumption. In the department of chemical industries the production of boracic acid (obtained from the lagoons of Tuscany) and of tartaric and citric acids, the manufacture of soap (of great consequence in Venice), and the preparation of alizarine or madder-red at the mouth of the Sarno, may be particularly mentioned. Among articles used for meat or drink, pickled meat and sausages (which are exported to a considerable extent), and liqueurs and rosolios, are the most important which are made in Italy. The sugar industry holds a very subordinate place, as does also the brewing of beer. The manufacture of tobacco is a state monopoly, and employs about 15,000 hands. The spinning and weaving industries in Italy are in some branches very highly developed. The most important of these are the silk manufactures, which form one of the chief sources of the national wealth. With the exception of Abruzzi, Basilicata, and the island of Sardinia, all the provinces of the kingdom take part in the preparation of the raw silk which is used in the manufacture, but this is more especially the case in Lombardy, Piedmont, and Venetia. The rearing of silkworms is more largely carried on in Italy than in any other country in Europe. Over 2,000,000 spindles are employed in spinning the silk, and the weaving is a very extensive branch of manufacture in Como, Genoa, Caserta, Milan, Turin, Florence, and Naples. Silk industries employ over 170,000 hands. The cotton manufacture is, as a textile industry, next to that of silk, and has greatly increased in recent years, the factories being chiefly in Lombardy, Piedmont, Lucca, and the Genoese district. About 1,900,000 spindles are now employed, the number of hands being 80,000. Woolen manufactures are carried on chiefly in Upper Italy, in Piedmont and Venetia, in the provinces of Novara, Vicenza, and Turin. The number of spindles at work is about 345,000, the

ITALY

looms about 9,000 (half being power-looms), the hands employed about 28,000. The import of woolen yarns, and still more so of woolen fabrics, is large. Flax, hemp, and jute support industries of some importance. Hand-spinning is general where the raw material is grown. Good fabrics are woven, although they are not able to compete with those made in England, France, Germany, and Austria. Hempen fabrics, which are chiefly produced in the provinces of Bologna and Ferrara, where rope-making also plays an important part, are articles of export. Tanning is carried on in almost every part of the peninsula. There are in several places, but chiefly Genoa and Naples, factories for the making of gloves, boots, and shoes, which are of excellent quality, and exported to various countries, and even to America. The paper manufacture is very flourishing, and great advances have been made in the processes employed. In the making of straw hats and other articles in plaited straw, Italy maintains the first place among the countries of Europe. The chief seat of this industry is in Tuscany (especially Florence and its environs), where it supports a great number of persons. The products of this manufacture are known all over the world. The making of furniture, and of articles of turnery, and articles used for personal adornment, as well as the manufacture of felt and silk hats, may be mentioned among the other manufacturing industries carried on in Italy.

Shipping and Navigation.—In 1901 the merchant marine of Italy consisted of 5,511 sailing and 446 steam vessels, of 945,008 tons burthen, the steamers being of 376,844 tons burthen, these figures including vessels engaged in the coasting trade and in fishing from 1 ton burthen upward. The total tonnage entered at Italian ports in 1901 amounted to 31,362,192 tons; cleared, 31,317,937 tons. The principal ports are Genoa, Leghorn, Messina, Naples, Palermo, Venice, and Catania, Genoa standing first and Naples second.

Railways, Telegraphs, and Post-office.—The length of the railways in operation, including Sicily and Sardinia, is now about 10,000 miles, of which considerably more than half belong to the state. The first line of railway was opened in 1839, but the process of construction was for a long time slow. In recent years the state has engaged in constructing railways, and has also obtained possession of others by purchase, but all are now worked by private companies. It is expected that when all the lines undertaken by the government have been completed, the total cost of construction will have amounted to 5,000,000,000 lire, or \$1,000,000,000. The expenditure in 1900 amounted to \$47,903,278, and the receipts to \$63,673,265, of which \$24,698,193 were from 60,029,673 passengers.

The total length of the telegraph lines in operation in the kingdom in 1900 was 27,918 miles, most of which belong to the state. The total number of inland despatches amounts to between eight and nine millions annually. The post-office in the course of the year now transmits considerably more than 373,000,000 letters and post-cards. The number of post-offices in the kingdom, including collecting boxes, is stated to be over 8,000.

Money, Weights, and Measures.—The monetary system of Italy is based on the Decimal System, the lira, equivalent to the French franc,

being divided into 100 centesimi. The lira is equal to about 20 cents. The weights and measures also, are those of the metric system, the French names having such modifications as are necessary to give them an Italian form. Thus the Italian gramma—the grammme, the chilogramma—the kilogramme, the litro—the litre, the ettolitro—the hectolitre, and so on; the metro—the mètre, the etometro—the hectomètre, the chilometro—the kilomètre, etc.; the aro—the are, the ettaro—the hectare; and the stero—the stère, and the decastero—the decastère. The quintale metrico is the same as the quintal metrique, and the tonnella the same as the tonneau metrique. See DECIMAL SYSTEM.

Banking.—There is no national bank in Italy and since 1893 only three banks of issue. The chief of these is the Bank of Italy, formed by the union of the National Bank of the Kingdom of Italy, founded in 1850, with a share capital of \$40,000,000, and having its chief seats in Florence, Genoa, Milan, Naples, Palermo, Rome, Turin, and Venice; with the National Bank of Tuscany, founded in 1857, share capital \$10,000,000; and the Tuscan Credit Bank, founded in 1860, share capital \$12,000,000. The other two banks of issue are the Bank of Naples, founded in the 16th century; and the Bank of Sicily, founded in 1843; chief seats, Palermo and Messina.

Constitution and Government.—The constitution of the kingdom of Italy is a limited monarchy. It is based upon the fundamental statute of 4 March 1848, fixing that of the kingdom of Sardinia. The throne is hereditary in the male line of the royal house of Savoy. The king attains his majority on completing his 18th year. He exercises the power of legislation only in conjunction with a national parliament, consisting of two chambers. The first chamber is called the senate, and is composed of the princes of the blood, and an indefinite number of members appointed for life by the king. These last must be above 40 years of age, and must be distinguished either by holding or having held some high office either in church or state, or by eminent services in literature, science, art, or any other pursuit tending to the benefit of the nation, or they must have paid for at least three years a sum not less than 3,000 lire (\$600) in direct taxes. In 1902 the senate numbered 356 members. The second chamber is called the chamber of deputies, and consists of 508 members, who are elected by a majority of all the citizens above 21 years of age who are in the enjoyment of civil and political rights, can read and write, and who pay direct taxes to the state or the provincial administration to the amount of 20 lire (\$4) yearly. Certain persons enjoy the franchise independently of the taxation test, such as members of learned academies and of chambers of commerce, professors, state officials, members of knightly orders, doctors, advocates, etc. For the election of the members of the chamber of deputies the whole country is divided into electoral colleges or districts. Any one who has the right of voting and has completed his 30th year may be elected, unless he be a clergyman or an officer of state. Some officers of state, however, may be elected. The king calls the chambers together every year. The sittings are public. The president of the senate is appointed by the king, that of the chamber of deputies is elected by the chamber itself.

ITALY

The chamber of deputies has the right of impeaching ministers of the crown, in which case the senate is the court before which the impeachment is tried.

The executive power of the state is exercised by the king through responsible ministers forming a council of ministers. In addition to this there is a state council possessing consultative powers, and authorized to decide on questions of competence arising between the administrative departments and the law-courts, as well as in cases of dispute between the state and its creditors. There are 11 departments in the government: 1, the ministry of foreign affairs, to which is attached the diplomatic council; 2, the ministry of the interior, with the supreme sanitary council, and the command of the national guard; 3, the ministry of justice and ecclesiastical affairs; 4, the ministry of finance, with the permanent council of finance; 5, the ministry of the treasury; 6, the ministry of war; 7, the ministry of marine, with the supreme council for naval affairs; 8, the ministry of public instruction, with the supreme council of instruction; 9, the ministry of public works, with the supreme council for public works; 10, the ministry of agriculture, manufactures, and commerce, with the councils for trade and manufactures, agriculture, mines, and woods and forests; and 11, the ministry of posts and telegraphs.

Finances.—The finances of Italy are not in a satisfactory condition, this being due partly to the expensive wars which were necessary in order to establish and consolidate the unity of the kingdom, partly to the increase of the public debt in consequence of the successive annexations of different portions of the Italian territory, since the present kingdom of Italy has naturally inherited the debt of each of the separate states of which it was formed partly to the large sums expended on railways and on the army and navy. At the end of 1874 the nominal capital of the whole Italian debt was valued at a sum equal to \$1,976,717,845. In 1901 the total debt was \$2,528,698,992. The difficulty experienced by the government in raising money to meet all its obligations has impelled it to resort to means which are, in some cases, extremely oppressive and unpopular (such as the grist tax), and in other cases scarcely creditable (state lotteries). The Italian budget divides the revenue and expenditure into ordinary and extraordinary. According to the budget of 1902-3 the total revenue estimated for that year was \$305,133,700, and the total expenditure \$362,472,708. For a number of years following the establishment of the kingdom (1861) the expenditure generally exceeded the revenue, the deficit rising in one year (1866) to \$123,400,000. From that date the deficit decreased steadily, and 1884-5 showed a surplus of \$12,000,000. Such a surplus, however, is rare, that for 1899-1900 being \$1,042,097. The progressive increase of the receipts to balance the expenditure is mainly due to two causes, the establishment of new taxes and the more careful collection of the old ones. Besides the general budget there is one for communes and another for provinces, both of which exhibit, if not an altogether satisfactory condition, at least an improving one.

Army and Navy.—By the law of 7 June 1875, supplemented by subsequent enactments, all men capable of bearing arms are under obligation of military service from the end of their

20th to the end of their 39th year. The forces are divided into three main branches: the standing army, the mobile militia, and the territorial militia. The regular time of service for the infantry is two or three years with the flag, six or five years in the reserve, three or four years in the mobile militia, and seven years in the territorial militia. The cavalry serve three years with the flag, six years in the reserve, and ten in the territorial militia. A certain number of the annual recruits (decided by the ballot) are only called on to serve under the flag from two to six months, which may be spread over several years. A third category have to engage in military exercises for only 30 days during the 19 years. The whole kingdom is formed into 12 military districts, each with an army corps. In 1901 the permanent standing army numbered in all 819,069, of whom 261,970 were actually serving with the flag. Of the latter 120,975 were infantry, 20,980 cavalry, and 32,563 artillery. The mobile militia numbered 320,170, the territorial militia 2,275,631. The total army strength was 3,356,920.

Great efforts have been made to strengthen the fleet in recent years, and it now possesses some powerful vessels. There are 14 battleships of the first class, two of which, the *Duilio* and *Dandolo*, have their citadel armor 22 inches in thickness. These are reputed to be among the most powerful war-ships yet constructed, each carrying four 100-ton Armstrong guns. Three others carry 105-ton guns. There are also 11 first-class cruisers, all decks protected. The total strength of the navy is 25,595 men, including 1,799 officers, of which the chief are one admiral, 21 vice- and rear-admirals and 203 captains.

Colonies.—Italy possesses the colony of Eritrea on the African shore of the Red Sea, and some territory in Somaliland. The total area of these possessions is about 188,000 square miles, with a population of about 850,000.

Ethnology.—The inhabitants of Italy are a mixture of many different races who have successively obtained the mastery of the country. Central Italy was the seat of several races which had partly been settled in the land from time immemorial, and were thence regarded as aborigines, and had partly immigrated from foreign countries. Among the former were the Sabellians, a powerful, warlike, freedom-loving people, subdivided into various tribes, the chief of whom were the Sabines, Samnites, and Æquians; the Umbrians, who dwelt to the north of the Sabellians, and are considered to be the most ancient of all the races inhabiting Italy; the Latin tribes, living to the west of the Samnites in the region called, from them, Latium; and the Oscans, Opicans, or Ausonians, living farther south than the Latins, being the earliest inhabitants of Campania. Among the latter races who came into Italy from foreign countries, the most remarkable were the Etruscans, who dwelt between the Gauls in the north, the Umbrians, the Latins, and the sea. The region on both sides of the Po (Padus) in Upper Italy was inhabited by a Gallic race, divided into numerous tribes and states possessing a number of towns on the coast as well as on the fruitful plain in the interior. Adjoining them on the northeast were the Venetians, and on the west coast the Ligurians. Lower Italy was occupied by Apulians in the southeast, supposed

ITALY

to be a member of the Oscan race; and by Lucanians, a Sabellian tribe; and the Brutii in the southwest, the former occupying the district to the south of Campania and Samnium, and extending as far as the root of the small peninsula in the extreme southwest, which was the habitation of the latter. The coasts of lower Italy as far north as Latium were studded many hundred years before Christ with Greek colonies, from whom the neighboring tribes derived some of the elements of Greek culture and an acquaintance with Greek mythology. Evidence of this is found in the Latin legend to the effect that after the destruction of Troy the hero Æneas, with a number of Trojan followers, came to Italy and formed a settlement in Latium, where he married the daughter of the Latin king.

The Gallic (Celtic) and the Roman elements have in the course of time become the principal ingredients of Italian nationality, but few traces of the character of the aboriginal population being now discernible. In upper Italy the Germanic element has contributed its share toward the formation of Italian nationality. Even the name of Lombardy is derived from that of a German tribe. In southern Italy and Sicily the Arab element enters into the mixture of national characteristics. The Italian has generally a fine exterior. He is slim rather than stout, but strong and agile. A dark complexion, an expressive countenance, sparkling eyes, black hair, and a grave gait combine to render the physique of the Italian characteristic and prepossessing. A great proportion of the inhabitants retain many of the characteristics of the Roman conquerors of the world. The predominating system of agriculture, however (see *Land Tenure*), the peasants being obliged to pay one half of their gross income to the landlords, and the minute subdivision of the soil, exert a depressing effect upon the condition of the lower classes.

Population.—The total population of Italy as shown in the table under *Political Divisions* was 32,475,253, or 293 people per square mile, as compared with 28,459,628 in 1881, thus showing an increase of about 14 per cent in 20 years. The foreign population in 1901 consisted of 37,706 residents and 23,709 transients, the majority being Austrians, Swiss, Germans, English and French. The natives of foreign extraction comprise 90,000 Albanians in southern Italy, 80,200 French in northern Italy, 31,200 Greeks in Calabria, 30,000 Slavs and 11,400 Germans in the northeast, and 9,800 Spanish in Sardinia.

Religion.—According to the provisions of the fundamental statute the Roman Catholic is the state religion, but all other creeds are tolerated, and adherents of all religions have equal municipal and political rights. The spiritual head of the Roman Catholic Church, the Pope, has his seat at Rome. His prerogatives are regulated by the law of 13 May 1871, which also determines the relation between church and state. By this law the person of the Pope is pronounced sacred and inviolable. The Italian government pays sovereign honors to the Pope, and guarantees him a yearly dotation of 3,225,000 lire (\$645,000). The Pope also enjoys the possession of the palaces of the Vatican and the Lateran, and the villa of Castel Gandolfo, without being subject to taxes on their account, and these places are not put under the jurisdiction of the state. Temporary residences of the Pope,

as well as places where a conclave or a council is held, are protected by similar immunities. The Pope is perfectly free in the exercise of his spiritual functions; and free intercourse is also guaranteed between the head of the church and the episcopate, as well as the whole Catholic world. The ambassadors of the Pope, and those accredited to the Holy See by foreign powers, enjoy all the privileges granted to such functionaries by international usage. The Church has the entire right of nominating to all ecclesiastical offices and benefices. The royal *exequatur* and *placet* are abolished. This *guaranty-law*, as it is called, which really determines the relations between church and state, at the present day, has never been acknowledged by the Popes, who have hitherto declined to accept the dotation. In the kingdom of Italy there are 51 archbishoprics and 223 bishoprics, beside 6 cardinal-bishops with sees in Italy. The number of parish priests is about 76,500. The monasteries and convents have been abolished by a royal decree dated 7 July 1866, and extended to the former Papal States, and to Rome itself, by another decree dated 25 June 1873. Among the Waldenses, who follow the religious observances of the Reformed Church, the highest spiritual authority is confided to a synod.

Judiciary.—For the administration of the law there are, beside numerous courts of first instance, 161 civil tribunals and the tribunals of correction, 92 assize courts, 24 courts of appeal, and 4 courts of cassation (at Turin, Florence, Naples, and Rome). The court of accounts occupies an independent position.

Local Government.—The constitution of the provinces and communes is based upon the law of 20 March 1865. Each province has the right of independent administration, and the executive power is entrusted to a provincial council, the members of which are elected by the communal electors for five years, and to a provincial deputation or commission elected by the council from its own members, and managing the business of the province when the council is not sitting. The provincial councils elect their own presidents and other officials. In each commune there is a communal council elected like that of the provinces for five years, and a municipal giunta elected by the council. The head of the communal administration is the sindaco, who in all the chief communes is elected by the council from among its own members, and in other cases is nominated by the king from the members of the communal council.

Education.—Compulsory education is enforced by the law of 15 July 1877, for all children who have completed their sixth year, and do not receive adequate instruction either at their homes or in private schools. Attendance is obligatory at the rudimentary schools in the commune for such children up to their ninth year, and in case of failure to pass the requisite examination they may be detained a year longer. The elementary communal schools are entirely supported by the municipalities, which nominate and pay the teachers, and carry out the educational laws under the supervision of the state school-inspectors. The subjects of compulsory instruction are reading, writing, arithmetic, the metric system, the rudiments of Latin, and the first duties of a man and a citizen. Religious instruction is not obligatory. There are many schools supported by the Church, as well as

ITALY

private schools, but all must adopt the government code, and are open to government inspection, while all teachers must hold the government certificate. The urgency of the need for all practicable measures being used to advance the cause of popular education in Italy may be gathered from a return issued by the Italian government in March 1870, which gives information regarding the amount of education received by the military conscripts born in 1847, and called up for active service in 1868, and shows that throughout the kingdom of Italy the average percentage, reckoned over the different provinces of the kingdom, of these conscripts who were totally unable to read or write was 64.27. In the province of Girgenti it was 85.82, and in the southern provinces generally it was above 80. The average percentage by 1897 had decreased to little more than 37. It is now comparatively rare to meet a boy or girl who cannot at least read. Education is practically free up to the university. Beside the regular day schools there are evening schools, in which elementary education may be carried further. The principal institutions for secondary education are the gymnasiums and lyceums, the former having a course of five years, the branches taught being Greek, Latin, Italian, history, geography, and arithmetic; the latter, having a course of three years, add to these subjects philosophy, mathematics, physics, chemistry, and natural history. No fees are charged either in gymnasium or lyceum. In addition to these there are a number of technical schools, in which fees are charged. There are also schools of agriculture, mining, commercial education, etc. For the higher education there are no less than 21 universities, many of them of ancient foundation, and at one time of considerable renown. The oldest are those of Bologna (founded in 1119), Padua (1222), Naples (1224), Rome (1244), Perugia (1320), Pisa (1329), Siena (1349), Pavia (1390), Turin (1412), and Parma (1422). The other universities are Cagliari, Camerino, Catania, Ferrara, Genoa, Macerata, Messina, Modena, Palermo, Sassari, and Urbino. The number of students at all the universities was returned in 1897-8 at 22,540, of whom Naples had 5,465, Turin 2,551, and Rome 2,300. In all universities the theological faculty has been abolished. Cooperating with these institutions for the education of the people there are about 150 training schools for teachers, with an attendance of about 18,000 students. There are government art schools at Bologna, Carrara, Florence, Lucca, Milan, Modena, Parma, Ravenna, Rome, Turin, Venice, etc., with a total of 3,300 pupils; and in addition the academies of Genoa, Bergamo, Verona, Siena, Pisa, and Perugia. Musical conservatories are supported by the government at Florence, Milan, Naples, Palermo, and Parma.

Emigration.—Military conscription, oppressive taxation, and the agricultural conditions already enumerated, are the causes of extensive emigration, the great bulk of which finds its way to the United States, Argentina, and Brazil, European nations adjacent to Italy also receiving their share. From 1870 to 1902 the total number of Italians who arrived in the United States amounted to 1,391,076. If to this is added the children born here, a total of 1,500,000 is reached. It is estimated that for 10 years Italian immigration will continue in the present proportion and

then gradually decrease, so that in 1920 the Italian population of this country will probably number from four to five millions.

The Italian immigration has a peculiar character. Until 1890 the percentage of women was less than 15, but now it has increased to 39. This indicates that the immigration has a marked tendency to become permanent. Thirty per cent or more of Italian adults who had been in this country more than 10 years went back at least once to Italy, and 80 per cent of these came to this country again, bringing their families with them. During the time in which the family is not here the man sends money weekly to Italy. It is calculated that about \$50,000,000 crosses the ocean every year in this way.

The Italian population in this country is changeable; roughly speaking, it is better the farther we go westward. New York has about 250,000 Italians, who are chiefly the worst kind of those coming to America. Philadelphia has about 80,000; Newark, N. J., 40,000; Boston, 25,000. In the New England States, where about 50 per cent of the entire population are foreigners, the Italian element is no more than 10 per cent, but is rapidly increasing. Cincinnati, Ohio, has only 5,000 Italians; Pittsburg, 12,000; Chicago, 15,000. California has about 60,000 Italians, of whom 25,000 are in San Francisco. The Italians in California are of the best kind, mostly Genoese, clean and intelligent.

Unfortunately many Italians coming from their farms abroad, who could be a valuable and strong agricultural element in this country, mass in the unclean and narrow quarters of the big cities. The only difficulty in directing them to the farming West, where they would be easily Americanized, is their ignorance of the state of things in this country and the lack of money to make the journey.

History.—Italy did not become the general name of this country until the age of Augustus. It was known to the Greeks under the name of Hesperia, and also, either in whole or in part, by those of Ausonia, Saturnia, and Enotria. The name of Italia was at first merely a partial name for the southern extremity. From the earliest times Italy was inhabited by many tribes of different origin. See paragraph on *Ethnology*. At an early period Rome, the chief town of Latium (founded, according to the received date, 753 B.C.), became predominant among the cities and tribes of Central Italy, and it gradually extended its influence over the whole country until, by the end of the 3d century B.C., it had brought into allegiance or subjection all the tribes of Italy from north to south, including those of the islands of Sicily, Corsica, and Sardinia. The history of ancient Italy thus merges to a great extent in that of Rome, to which article, as well as those treating of the more important races of Italy, the reader is referred for further information concerning ancient Italy, while the subsequent history of Italy is resumed from the overthrow of the empire in the west, 476 A.D.

From 476 to 568 Italy was under the dominion of the Herulians and Rugians, and of the Ostrogoths. Odoacer, the leader of the Roman-Germanic troops, dethroned the Emperor Romulus Augustus, assuming the title of King of Italy, and after ruling 12 years was defeated by Theodoric, king of the Ostrogoths, who

ITALY

ruled over Italy with Ravenna as his capital. Theodoric, who combined the vigor of the north with the cultivation of the south, is justly termed the Great, and, under the name of Dietrich of Bern (Verona), has become one of the principal heroes of old German story. About 568 the country was invaded by the Lombards (Langobardi, Longobardi), a German people which had emigrated from the Elbe to Pannonia. Under King Alboin they conquered the Po basin, which received from them the name of Lombardy. The kingdom of the Lombards included Upper Italy, Tuscany, and Umbria. Alboin also created the Duchy of Benevento, in Lower Italy, with which he invested Zotto. The popes, in their efforts to defend the freedom of Rome against the Lombards, had recourse to the Frankish kings. In consideration of the aid expected against King Astolphus, Pope Stephen III. (754) anointed Pepin, who, with the approbation of Pope Zacharias, had been made king of the Franks in 752, and with the assent of the municipality of Rome, appointed him patrician. In 756 Pepin presented the exarchate of Ravenna, with the five cities, to the Pope. At the invitation of Pope Hadrian I. Charlemagne made war upon Desiderius, the king of the Lombards, took him prisoner in his capital, Pavia, united his empire with the Frankish monarchy (774), and eventually gave Italy a king in his son Pepin. Charlemagne was unsuccessful in his attempts against the Duchy of Benevento, the independence of which was maintained by Duke Arichis, and against the republics in Lower Italy, where Naples, Amalfi, and Gaeta in particular, had become rich by navigation and commerce. Leo III. bestowed on the king of the Franks, on Christmas day, 800 A.D., the imperial crown of the West. But dislike to the Franks united the free cities, Rome excepted, more closely to the Eastern Empire. During the lifetime of Charlemagne Frankish Italy was given to his grandson Bernard (810), who having attempted to become independent of his uncle, Louis the Debonnaire, was deprived of the crown, and had his eyes torn out. Italy now remained a constituent part of the Frankish monarchy, till the partition of Verdun (843), when it was allotted, with the imperial dignity, and what was afterward called Lorraine, to Lothaire I., eldest son of Louis. Lothaire left the government (850) to his son Louis II., the most estimable of the Italian princes of the Carlovingian line. After his death (875) Charles the Bald of France first took possession of it, and after his death (877) Carloman, who was succeeded, in 884, by his brother Charles the Fat, who united the whole Frankish monarchy for the last time. His dethronement (887) was the epoch of anarchy and civil war in Italy. Berengarius, duke of Friuli, and Guido, duke of Spoleto, disputed the crown between them. Guido was crowned king and emperor, and after his death (894) his son Lambert, although Berengarius got himself crowned king in the same year. Arnulf, the Carlovingian king of the Germans, enforced his claims to the royal and imperial crown of Italy (896), but like most of his successors was able to maintain them only during his residence in the country. After the death of Lambert (898) and Arnulf (899) the struggle for supremacy in Italy continued, the competitors now being Berengarius, of Friuli, and Louis, king of Lower

Burgundy (Arles), but at last the former succeeded in restoring quiet by driving out his rival. He reigned from 915 when he was crowned emperor till 924, when he was assassinated. Hugh of Provence, who succeeded, sought to strengthen the insecure throne of Italy by a bloody tyranny. His nephew, Berengarius, marquis of Ivrea, fled to Otho the Great of Germany, assembled an army of fugitives, returned, and overthrew Hugh (945), who was succeeded by his son Lothaire. Berengarius became his first counsellor, and after the death of Lothaire, in 950, poisoned, it was said, by Berengarius, wished to compel his widow—the beautiful Adelaide—to marry his son. Escaping from his cruelty she applied for aid to Otho I., king of Germany, who passed the Alps, conquered Pavia, became king of the Franks and Lombards (in 951), and married Adelaide. To the cession of Friuli, the key of Italy, which Otho gave to his brother Henry, Berengarius was indebted for permission to reign as the vassal of Otho. But 10 years after, on complaints, Otho returned (961), deposed him, and led him prisoner to Bamberg. Early in the following year (962) Otho was crowned emperor by Pope John XII., thus uniting Italy with Germany, and from this event dates the foundation of what is known in history as the Holy Roman Empire.

Otho granted to the Italian cities privileges that were the foundation of a free constitution. Owing to the corruption existing in the Papal Court he deposed John XII., who had crowned him emperor, and chose Leo VIII. in his stead; but the people, jealous of its right of election, chose Benedict V. From this time the popes instead of ruling the people of Rome, became dependent on them. In Lower Italy the Republics of Naples, Gaeta, and Amalfi defended their independence against the Lombard duchy of Benevento, with the more ease in that they had a common enemy in the Saracens, who previously invited over from Sicily by both parties (about 830), as auxiliaries against each other, had settled and maintained themselves in Apulia. Forty years later the Greeks in Lower Italy, who had adhered to the Byzantine Empire, succeeded, with the aid of Louis II. of Germany, in recovering the territory that had been wrested from them by the Saracens, and out of the recovered region formed a separate province, called the Thema of Lombardy, which continued under their dominion upward of a hundred years, being governed by a capitan (governor-general) at Bari. Otho the Great did not succeed in driving them from Italy, and the marriage of his son, Otho II., with the Greek princess Theophania, put an end to his exertions for this purpose.

In opposition to the designs of the Count of Tusculum, who wished to supplant the absent emperor at Rome, a noble Roman, the consul Crescentius, attempted to govern Rome under the semblance of her ancient liberty (980). Otho II., king since 973, occupied with his projects of conquest in Lower Italy, did not interfere with this administration, which became formidable to the two popes Boniface VII. (anti-pope) and John XV. But when Otho III., who had reigned in Germany since 983, raised his kinsman Gregory V., to the papedom, Crescentius caused the latter to be expelled, and John XVI., a Greek, to be elected by the people. He also endeavored to place Rome again under the nominal supremacy of the Byzantine Em-

ITALY

pire. Otho, however, reinstated Gregory, besieged Crescentius in the castle of San Angelo, took him prisoner, and caused him to be beheaded with 12 other noble Romans (998). But the Romans again threw off their allegiance to the emperor, and yielded only to force. On the death of Otho III. (1002) the Italians considered their connection with the German Empire as dissolved. Harduin, marquis of Ivrea, was elected king, and crowned at Pavia, whereupon Milan, the enemy of Pavia, declared for Henry II. (in Italy, I.) of Germany. A civil war ensued, in which every city, relying on its walls, took a greater or less part. Henry was chosen king of Italy by the nobles assembled in Pavia; but disturbances arose in which a part of the city was destroyed by fire (1004 A.D.). Not till after Harduin's death (1015) was Henry recognized as king by all Lombardy. He was succeeded by Conrad II. (in Italy, I.). When Henry III. (in Italy, II.), the son of Conrad, whom he succeeded in 1039, entered Italy (1046), he found three papal claimants in Rome, whom he deposed, appointing in their stead Clement II., and ever after filled the papal chair, by his own authority, with virtuous German ecclesiastics. Henry died in 1056. During the long minority of his son Henry IV. (in Italy, III.) the policy of the popes, directed by the monk Hildebrand (afterward Gregory VII.), succeeded in creating an opposition which soon became formidable to the secular power. (See POPES.) The Normans also contributed to this result. As early as 1016 warriors from Normandy had established themselves in Calabria and Apulia. Allies sometimes of the Lombards, sometimes of the republics, sometimes of the Greeks against each other and against the Saracens, they constantly became more powerful by petty wars. The great preparations of Leo IX. for their expulsion terminated in his defeat and capture (1053). Nicholas II. united with the Norman princes, and, in 1059, invested Robert Guiscard with all the territories conquered by him in Lower Italy. From that time the Pope, in his conflicts with the imperial power, relied on the support of his faithful vassal, the duke of Apulia and Calabria, to which Sicily was soon added. While the small states of the south were thus united into one large kingdom, that in the north was dissolving into smaller states. The Lombard cities were laying the foundation of their future importance. Venice, Genoa, and Pisa were already powerful. The Pisanese, who, in 980, had given to Otho II. efficient aid against the Greeks in Lower Italy, and in 1005 boldly attacked the Saracens there, ventured, in connection with the Genoese (no less warlike and skilled in navigation), to assail the infidels in their own territory, and twice conquered Sardinia (1017 and 1050), which they divided into several large fiefs, and distributed them among their principal citizens.

Gregory VII. humbled Henry VII. in 1077. Urban II. instigated the emperor's own sons against their father. Conrad, the eldest, was crowned king of Italy in 1093, after whose death (1101) Henry, the second son, succeeded in deposing his father from the imperial throne. Henry V., the creature of the Pope, soon became his opponent; but after a severe conflict concluded with Calixtus II. the concordat of Worms (1122). A main issue which remained unsettled gave rise to new difficulties in the 12th and

13th centuries—Matilda, countess of Tuscany, who died in 1115, by a will, the validity of which was disputed by the emperor, bequeathed all her property to the Papal See. Meanwhile, in the south, the Norman state, under Roger II., was formed into a kingdom, from the ruins of republican liberty and of the Greek and Lombard dominion (1130). In the small republics of the north of Italy the government was in most cases divided between the consuls, the lesser council (*credenza*), the great council, and the popular assembly (*parlamento*). Petty feuds developed their youthful energies. Such were those that terminated with the destruction of Lodi by Milan (1111), and the 10 years' siege of Como by the forces of the same city, allied with those of nearly all the Lombard cities (1118-27). The subjugation of this city rendered Milan the first power in Lombardy, and most of the neighboring cities maintained an alliance with her. Others formed a counter-alliance with her antagonist, Pavia. In Rome the love of liberty, restrained by Gregory VII., rose in proportion as his successors ruled with less energy. The schisms between Gelasius II. and the antipope Gregory VIII., Innocent II. and the antipope Anacletus II., renewed the hopes of the Romans. Arnold of Brescia (q.v.), formerly proscribed (1139) for his violent attacks against the luxury of the clergy in that country, was their leader (1146). After eight years Adrian IV. succeeded in effecting his execution. Frederick I. of Hohenstaufen (called Barbarossa) crossed the Alps six times, in order to defend his possessions in Italy against the republicanism of the Lombard cities. Embracing the cause of the Pavian union as the weaker, he devastated (1154) the territory of Milan, destroyed Tortona, and was crowned in Pavia and Rome. In 1158 he reduced Milan, demolished the fortifications of Piacenza, and in a diet at Roncaglia extended the imperial prerogatives conformably with the Justinian code, gave the cities chief magistrates (*podestà*), and proclaimed a general peace. His rigor having excited a new rebellion, he reduced Crema to ashes (1160), compelled Milan to submission, and demolished the fortifications (1162). Nothing, however, but the terror of his arms upheld his power. When the emperor entered Italy (1163) without an army, the cities concluded a union for maintaining their freedom, which in 1167 was converted into the Lombard Confederacy. In 1176 he suffered a severe defeat at Legnano, and was obliged to conclude a concordat with Alexander III., and a truce with the cities at Venice. Some years afterward a peace, which secured their independence, was signed at Constance (1183). The republics instead of strengthening their league into a permanent confederacy were soon split into new factions, most cities being internally divided into Guelphs and Ghibellines (q.v.). After Frederick II. returned from his crusade (1229), for undertaking which contrary to the will of the pope he was excommunicated, he waged war, with varying success, against the cities and against Gregory IX., heedless of the excommunication. The plan of Gregory IX. to depose Frederick, was followed by Innocent IV. in the Council of Lyons (1245), whither the Pope had fled to be out of the power of Frederick. This greatly weakened the Ghibelline party; the hitherto faithful Parma revolted; and the war between

ITALY

Guelfs and Ghibellines raged with greater fury than ever. In 1250 Frederick died, and his sons Conrad IV. and Manfred, endeavored to maintain themselves in the possession of their hereditary dominions in Lower Italy; but Innocent IV., who now returned to Italy, excommunicated them, and his successor, Urban IV., offered the crown of Naples to Charles of Anjou, brother of Louis IX. of France, who accepted the offer and landed at the mouth of the Tiber in 1265.

With Charles I. of Anjou, king of Naples, senator of Rome, and Papal vicar in Tuscany, the names of Guelfs and Ghibellines acquired a new signification. The former denoted the friends, the latter the enemies, of the French. Although with the fall of Hohenstaufen the power of the German emperors in Italy was practically at an end for the time, yet in Lombardy, and to some extent also in Tuscany, their supremacy was still at least nominally recognized; many Ghibellines still looked forward to a restoration of the Holy Roman Empire in Italy as the only means of reestablishing order, and others wishing to gratify their own schemes of ambition, often sought to obtain a legal authority for their usurpations by purchasing from the empire the title of imperial vicars. In Sicily, by the so-called Sicilian Vespers (1282), the French were driven out, and the crown of the island was bestowed upon Peter of Aragon, the son-in-law of Manfred, with whose help the inhabitants successfully resisted all the attempts of Charles of Anjou to recover the island, which remained separate from Naples for nearly 150 years. Thus the house of Aragon came to be the natural allies of the Ghibellines, as the house of Anjou were the allies of the Guelfs. To the factions of Guelfs and Ghibellines were added in the republics the parties of the nobility and the people. Everywhere in Middle and Upper Italy there was anarchy and civil war. The noble exertions of Gregory X. (who died 1276) to establish peace were of no avail; those of Nicholas III. (1277-81), who feared the preponderance of Charles, were more efficacious; but Martin IV. (1281-5), servilely devoted to Charles, destroyed everything which had been effected, and persecuted the Ghibellines with new animosity. A different interest—that of trade and navigation—impelled the maritime republics to mutual wars. The Genoese assisted Michael Palaeologus (1261) to recover Constantinople from the Venetians; at Meloria, they annihilated (1284) the navy of the Pisans, and completed their dominion of the sea by a victory over the Venetians at Curzola (1298). In Tuscany the party of the Guelfs formed themselves under the leadership of Florence and the influence of the Church into a league for the maintenance of national freedom against imperial power. Only Pisa and Arezzo remained attached to the Ghibelline cause. In Lombardy many towns, such as Novara, Lodi, Vercelli, Asti, Cremona, and above all Milan, formed themselves into a Guelph confederacy; but there was on the one hand an equally strong Ghibelline confederacy, consisting of the cities of Verona, Mantua, Treviso, Parma, Piacenza, Reggio, Modena, and Brescia. Freedom seemed to have expired, when the people, weary of the everlasting feuds of their tyrants, rose in most of the cities, and expelled them (1302-6), including the Visconti,

who had supplanted the Della Torre (1277) in the government of Milan.

Henry VII., the first emperor who had appeared in Italy for 60 years (1310), restored the princes to their cities. Florence alone undertook the glorious part which she so nobly sustained for two centuries, as the guardian of Italian freedom, chose Robert of Naples, the enemy of Henry, her protector for five years (1313), and remained free while Italy swarmed with tyrants. Robert also held the dignity of Papal vicar in the States of the Church during the pontificates of John XXII. and Benedict XII., the popes then residing at Avignon under the influence of France in what is known as the second Babylonian captivity. In the other cities a rule of tyranny existed, frequently changing from family to family, and therefore more oppressive. These petty princes, especially Della Scala, Matteo Visconti, and Castruccio, were a counterpoise to the ambitious views of Robert of Naples, son of Charles II. of Naples.

About 1334 Martino della Scala, master of half Lombardy and of Lucca, began to menace the freedom of Lombardy. Florence led the opposition against him, and excited a war of the league, in which it gained nothing but the security of its liberty. After the baffled Martino had sold Lucca to the Florentines the Pisans arose and conquered it for themselves (1342). In Rome, still torn by the feuds of the nobles, Cola di Rienzi (1347) sought to restore order and tranquillity; he was appointed tribune of the people, but was forced, after seven months, to yield to the nobility.

In 1348 the emperor Charles IV. made an expedition into Italy from which may be dated the gradual extinction of the political parties of Guelfs and Ghibellines. Charles had himself crowned king of Lombardy at Milan, and emperor at Rome, but he saw that neither of the Italian parties really desired foreign domination, and that the Ghibellines merely gave the empire their support for their own party purposes, and he therefore did not seek to strengthen himself by attaching himself to either party, but was content to add to his resources for the government of the empire in Germany by selling to the towns and princes the imperial rights in Italy. In 1425 the Venetians in alliance with the Florentines conquered all the territory of north-eastern Italy as far as the Adda, which they retained in the Peace of Ferrara in 1428. Milan, Venice (which possessed half of Lombardy), Florence (wisely managed by Lorenzo Medici), the States of the Church (for the most part restored to the Holy See), and Naples (which was incapable of employing its forces in direct attacks on other states), constituted, in the 15th century, the political balance of Italy, which, during the manifold feuds of these states, permitted no one to become dangerous to the independence of the rest, till 1494, when Charles VIII. of France entered Italy to conquer Naples as the inheritance of the house of Anjou. After an unresisted march through Italy Charles took possession of Naples; but a league was formed against him by the leading Italian states, who were joined by Ferdinand of Aragon, and he was compelled hastily to retreat, leaving only a small body of troops to protect his new conquest. In 1496 the whole of Naples was reconquered from the French and the Aragonese dynasty restored. Louis XII. the successor of

ITALY

Charles VIII., resumed the plans of the latter, and with Ferdinand of Spain as ally, having conquered Naples, fell to disputing as to the division of their conquest. War was declared between them, the result of which was that Ferdinand managed to retain the whole conquest for himself, which was thus reunited to Sicily and Aragon (1501-4). Louis was more successful against Milan, which he subjected in 1500. The attempts of Cesare Borgia, the son of Pope Alexander VI., to acquire the sovereignty of Italy were frustrated by the death of his father (1503), when the war-like Pope Julius II. completed the subjugation of the States of the Church. He concluded with Maximilian I., Ferdinand the Catholic, and Louis XII. the league of Cambrai (1508) against the ambitious policy of the Venetians, who artfully succeeded in dissolving the league, which threatened them with destruction. The Pope then formed the so-called Holy League with the Venetians themselves, Spain and the Swiss, for the purpose of driving the French from Italy. Maximilian Sforza, who had reacquired Milan (1512), relinquished it without reserve to Francis I. (1515) after the battle of Marignano, but the Emperor Charles V. assumed it as a reverted fief of the empire, and conferred it on Francesco Sforza, brother of Maximilian (1520). This was the cause of violent wars, in which the efforts of Francis were always unsuccessful. He was taken prisoner at Pavia (1525), and, with his other claims, was compelled to renounce those on Milan. In 1530 Florence, which through inner demoralization had lost its ancient love of freedom, was converted into a regular principality under Alessandro de' Medici, who was imposed on the Florentines by Charles V. Genoa, subject to the French since 1499, found a deliverer in Andrea Doria (1528). In 1553, beside Milan Charles V. conferred Naples on his son Philip II., and for a century and a half the Austro-Spanish influence was predominant in Italy. In the second half of the 16th century the prosperity of Italy was increased by a long peace, as much as the loss of its commerce allowed. Misfortunes in Germany compelled Ferdinand II. to confer both countries as a fief on Charles of Nevers, the *protégé* of France, whose family remained in possession till the war of the Spanish Succession. The peace of Italy was not interrupted during the second half of the 17th century, except by the attempts of Louis XIV. on Savoy and Piedmont, and appeared to be secured for a long time by the treaty of neutrality at Turin (1696), when the war of the Spanish Succession broke out. Austria conquered Milan, Mantua, and Montferrat (1706), retained the two first (Mantua was forfeited by the felony of the duke), and gave the last to Savoy. In the Peace of Rastatt (1714) Austria obtained, moreover, Sardinia and Naples; Savoy obtained Sicily, which it exchanged with Austria for Sardinia, from which it assumed the royal title. The house of Farnese becoming extinct in 1731, the Spanish Infant Charles, son of Elizabeth Farnese, daughter of the eldest brother of Antonio, the last duke of the Farnese family, obtained Parma and Piacenza. In the war for the Polish throne, of 1733, Charles Emmanuel of Savoy, in alliance with France and Spain, conquered the Milanese territory, and received therefrom, in the Peace of Vienna (1738), Novara and Tortona.

Charles, infant of Spain, became king of the Two Sicilies, and ceded Parma and Piacenza to Austria. The Medici of Florence, entitled, since 1575, grand-dukes of Tuscany, became extinct in 1737; and Francis Stephan, duke of Lorraine, then received Tuscany by the preliminaries of Vienna, and, becoming emperor in 1745, made it the appanage of the younger line of the Austro-Lorraine house. In the war of the Austrian Succession the Spaniards conquered Milan (1745), but were expelled thence by Charles Emmanuel, to whom Maria Theresa ceded in reward some Milanese districts. Massa and Carrara fell to Modena in 1743 by right of inheritance. The Spanish Infant, Don Philip, conquered Parma and Piacenza in his own name, lost them, and obtained them again as a hereditary duchy by the Peace of Aix-la-Chapelle (1748). Thus in the 18th century the houses of Lorraine, Bourbon, and Savoy possessed all Italy with the exception of the ecclesiastical territories, Modena, and the republics, which beheld with apathy operations in which they had no share. A quiet of 40 years ushered in their downfall.

The French revolution had a great influence on the history of Italy. From 1792 to 1797 Italy was overrun by the victorious French troops under Bonaparte and in the latter year the Pope purchased peace by the cession of Bologna, Ferrara, and Romagna in Italy, and Avignon in France; the payment of a money indemnity, and the surrender of art treasures. Bonaparte then advanced into Austrian Germany, and a rising having taken place among the Venetians in his rear, he made this a pretext for overthrowing the Venetian state. In October 1797 the Peace of Campo Formio was concluded, by which the Cisalpine Republic (q.v.) was formed out of the Italian territories which had been surrendered by Austria and the Pope, together with some sections taken from other powers. Austria received in compensation Venetia and Dalmatia. A few days later Sardinia concluded a treaty of alliance with France. The French then advanced toward Rome, overthrew the ecclesiastical government, and erected a Roman republic (1798). In Genoa, in the same year, Bonaparte occasioned a revolution by which a democratic republic was formed after the model of the French, under the name of the Ligurian Republic; and Lucca also was obliged to accept a republican form of government. In 1798 the second coalition against France was formed, and the king of Naples, instigated by his wife, a daughter of Maria Theresa, sent a Neapolitan army to attack the French at Rome. The French were at first driven out, but soon returned, and repulsed the Neapolitan army, forcing it to retreat into its own territory, where they followed it, and having taken the capital after an obstinate resistance, erected Naples into the Parthenopean Republic. The French directory also compelled the king of Sardinia to surrender his territories on the continent, and Piedmont and Tuscany received a military administration. In consequence of the victories of the coalition, the French were again driven out of Rome, Naples, and the rest of Italy except Genoa, and the king of Sardinia and the Pope returned to their capitals; but in the brilliant campaign of 1800 Napoleon destroyed all the advantages gained by the allies in Upper Italy, the most of which he reconquered. By the Peace

ITALY

of Luméville the possession of Venice was confirmed to Austria. The Duke of Parma received Tuscany, and afterward from Bonaparte the title of King of Etruria. Parma was united with France. The Cisalpine and Ligurian Republics were guaranteed by Austria and France, and with the Ligurian territories were united the imperial fiefs included within their limits. The king of Naples, who had occupied the States of the Church, was obliged to conclude peace at Florence. By Russian mediation he escaped with the cession of Piombino, the Stato degli Presidj, and his half of the Island of Elba, together with the promise of closing his harbors against the British. The other half of Elba Tuscany had already relinquished to France; but the whole island was obstinately defended by the British and Corsicans, with the armed inhabitants, and not evacuated till autumn. In January 1802, the Cisalpine Republic was transformed into an Italian republic, formed on the model of the new French constitution, and Bonaparte became president. Genoa also received a new constitution, and Girolamo Durazzo for doge. Piedmont, however, was united with France. After Bonaparte had become emperor in 1804 he attached (17 March 1805) the royal crown of Italy to the new imperial crown; he promised, however, never to unite the new monarchy with France, and even to give it a king of its own. The new constitution was similar to that of the French Empire. Napoleon founded the order of the Iron Crown, and having placed the crown on his own head at Milan 26 May, appointed his stepson Eugène Beauharnais viceroy of Italy. No European power recognized expressly the Italian kingdom of Napoleon. The emperor continued to strengthen his power against the active enemies of the new order of things. He seized Dalmatia, and annexed it to the kingdom of Italy. Guastalla, the Ligurian Republic, Parma and Piacenza were made French provinces. The Pope was obliged to sanction the imperial coronation by his presence. Naples was occupied by the French, and Napoleon gave it as a kingdom to his brother Joseph; and afterwards, in 1808, when Joseph was nominated to the throne of Spain, to Joseph Murat, grand-duke of Berg; while the English secured the rightful king Ferdinand in the possession of Sicily. In 1808 Etruria was annexed to France, and in 1809 Tuscany was given to Napoleon's sister Elise as a grand-duchy. In the same year (1809) the States of the Church were entirely united to France. After the Peace of Venice, Istria and Dalmatia were separated from the kingdom of Italy, and incorporated with the newly-created kingdom of Illyria. Bavaria was obliged to cede to Italy the circle of the Etsch (Adige) in the Tyrol, a part of the circle of Eisack, and the district of Clausen.

The power of the French emperor was, to all appearance, as firmly established in Italy as in all Europe, but after the fatal retreat from Russia, Murat, whom Napoleon had personally offended, deserted the cause of France, and joined Austria, whose army penetrated into Italy under Bellegarde. After the truce of 21 April 1814, the French troops evacuated Italy, and most of the provinces were restored to their legitimate sovereigns. But before the Congress of Vienna had organized the political relations of Europe, Napoleon escaped from Elba and effected his return to France, 1 March 1815. At

the same time Murat, king of Naples, abandoned his former ambiguous attitude, and took up arms, as he pretended, for the independence of Italy. But his appeal to the Italians was answered by a declaration of war by Austria. Driven from Bologna by the Austrian forces, and totally defeated by Bianchi at Tolentino, he lost the kingdom of Naples, seven weeks after the opening of the campaign. Ferdinand IV. returned from Palermo, and Murat's family found an asylum in Austria. Murat himself made a descent in Calabria from Corsica, in order to recover his lost kingdom, but was taken prisoner at Pizzo, brought before a court-martial, and shot 14 Oct. 1815.

Meanwhile the Congress of Vienna had arranged the affairs of Italy, so that Austrian predominance was again more firmly established than ever in Italy.

The result was to leave the country in the same divided condition and among the people. The spirit of Carbonarism (see CARBONARI), having for its object the union of Italy under one government, threatened to subvert the political institutions. In Naples and Sicily, in 1820 Ferdinand I. (IV.) was compelled to promise a constitution similar to that granted to Spain in 1812; and in Sardinia, Victor Emmanuel abdicated in 1821 in favor of his brother Charles Felix. But Austria, as the power most nearly concerned, undertook, with the approbation of the other powers assembled at the Congress of Laibach, to restore despotism in Naples and Sicily as well as in Sardinia. The system of repression was carried out with the utmost rigor, and great cruelties were practised in Naples and Sicily, even on those who were only the objects of political suspicion.

The arbitrary proscriptions and imprisonments aroused a deep hatred of the government, and when, in 1830, in consequence of the French revolution, a general spirit of revolt spread itself throughout Europe, the Italians considered the state of events a favorable conjuncture for striking a blow for national and political freedom. But the hopes of the patriots were soon quenched. The risings in Modena, Parma, and Bologna were suppressed by Austrian troops, and the reigning princes who had been driven out of the first two states returned to their dominions. In the States of the Church the papal troops, recruited from banditti and criminals, were employed to put down the uprisen provinces, and they behaved with so much violence that Austrian forces were necessary to defend the government and country from their own soldiers. In order not to allow all the power in Italy to fall into the hands of the Austrians the French suddenly occupied Ancona in February 1832, and retained it for several years. In 1834 an invasion of Savoy from Switzerland by a band of Italian and Polish exiles under the Genoese Ramorino, undertaken with the purpose of overthrowing the Sardinian throne, and then in conjunction with the Italian patriots, headed by Mazzini, who gave themselves the name of "Young Italy," bringing about a revolution throughout the whole country, ended in a miserable failure.

But the unwearyed activity of the secret societies, more especially of Mazzini's "Young Italy," with its republican tendencies, diffused itself over a great part of the peninsula. In 1838 Ancona was evacuated by the French; and

ITALY

at the same time the Austrian troops quitted the Papal States, while the amnesty, proclaimed a short time previously in Venice and Lombardy, appeared to produce a lasting conciliatory effect on the minds of the people. Pope Gregory XVI. died in June 1846, and the election of Cardinal Mastai Ferretti to the papacy under the name of Pius IX. seemed to mark an epoch in the history of Italy, for the spirit of reform which he introduced into the government of the Papal States soon spread to Tuscany and Sardinia. But Naples and Austria strongly opposed the new system of politics. Naples suppressed the violent attempts made in the summer of 1847, without putting a stop, however, to the increasing ferment. In Lombardy, Austria maintained the old system, and by the investment of Ferrara in August 1847 made an unmistakable declaration against the papal policy. Throughout the whole of Italy a hatred of the Austrian sway was systematically cherished, and to the whole movement a hostile direction was gradually given against Austria. In January 1848 the inhabitants of the island of Sicily were in rebellion, demanding a constitution and ultimately the complete severance of the island from the continental government.

At this juncture occurred the French Revolution of 1848, and the reserve which had hitherto prevailed in Upper Italy was thrown aside, and the overwhelming intelligence of the insurrection in Vienna soon completed the universal eruption. The insurrection at Milan, on 22 March, followed by similar commotions throughout almost the whole of north Italy, compelled the Austrian army, under Field-marshal Radetzky, to evacuate the capital and retreat to Verona; while, at the same time, Venice, by the hasty capitulation of the authorities, recovered its independence, and the reign of despotism came to an end in Parma and Modena. Charles Albert, king of Sardinia, with the hope of making himself master of the Lombardo-Venetian kingdom, and carrying out his idea of a national Italian confederacy, declared war with Austria, and, supported by numerous Italian free companies during the first period of enthusiasm and surprise, drove back the enemy's troops to the northern frontier of Italy. But on 6 May Radetzky (then in his 82d year) successfully withstood the attacks of the Italians at Santa Lucia, not far from Verona, and on 25 July gained at Custoza a second bloody victory, which resulted in the reconquest of Milan and the whole of Lombardy. The king of Sardinia made his escape by night into his own territories, and then concluded an armistice with the victors. Pushed on by the democrats, Charles Albert renewed his attempts in the following year (1849), but in a campaign of five days (20-24 March) the old field-marshall put a speedy termination to the enterprise, and frustrated the hopes of the Italian patriots. Charles Albert, despairing of his fortunes, abdicated in favor of his son, Victor Emmanuel, and fled from his dominions. The young king then concluded a disadvantageous peace with Austria. Venice, favored by its position, resisted for some months longer the besieging army of the Austrians, but was at last obliged to surrender (25 Aug. 1849). In other parts of Italy events had meanwhile taken a similar course. In Rome, where Pope Pius IX., alarmed at the sudden outburst of revolutionary projects, checked himself in his career of reform,

the excitement grew to such a pitch that he lost all control of his subjects. In vain he promised a constitution and summoned an assembly of the states to the capital. His minister Rossi was assassinated in November 1848, whereupon the democrats took all the power into their own hands. The Pope fled in terror to Gaeta, leaving his capital in the hands of the populace and the insurgent volunteers, who proclaimed a Roman republic, and even laid hands on the Church property (February 1849). Mazzini, the active head of "Young Italy," and Garibaldi, the leader of the volunteers, ruled in Rome. The Pope appealed to the protecting states for help, and a French army under Gen. Oudinot marched up to the walls of Rome and demanded the restoration of the old order of things. When this was refused the French proceeded to lay siege to the city, but met with so determined an opposition that it was only after frequent bloody contests, extending over several weeks, that the city fell into their hands (July 1849). The republicans sought safety in flight, a French garrison was permanently posted in Rome, and under the protection of French bayonets the old condition of affairs was gradually restored. The insurgent Sicilians had no better success than the Lombards, Venetians, and Romans, being gradually subdued by the Neapolitan arms. In Tuscany, as in Rome, the democrats for a short period obtained the upper hand and compelled the grand-duke to flee, but the republican form of government lasted only a few weeks. Sardinia, therefore, remained the only state which preserved the constitutional benefits resulting from 1848, and strenuously withstood all requisitions to act otherwise. The Lombardo-Venetian kingdom entered the states of the Austrian union, whilst, notwithstanding some isolated conciliatory measures, such as the reestablishment of a free port at Venice, the system of military dictatorship was still maintained. In Rome, which the Pope again entered in April 1850, the new organization of the state restored the spiritual rule, with a silent abrogation of the constitution of 1848. In Naples the last miserable shadow of freedom was abolished, and against the originators and promoters of the insurrection of 1848 there was opened an array of legal proceedings, the tyrannies of which engaged deeply the attention of foreign countries. In Tuscany, which was occupied by Austrian troops and wholly bound to Austria by a military convention, despotism and priestly power returned in all their force. In Modena and Parma the returned princes, relying on the protection of Austria, pursued a policy of revenge and repression against the adherents of a free political life. In such circumstances the condition of Italy, harassed and unsettled, presented a most melancholy picture; nor could some important non-political improvements, including the formation of railways, the accession to the Austrian postal union, and the freedom of the navigation of the Po, effect any satisfactory amelioration. In Naples the cruelties exercised on political prisoners led to a cessation of intercourse between that state and Great Britain, and Austrian oppression in Lombardo-Venetia, the misgovernment of the Papal States and of the duchies, abetted by Austria, led to the war of 1859, when France, siding with Sardinia, defeated the Austrians at Magenta (4 June) and Solferino (24 June), and drove them out of Lombardy,

ITALY

after which Francis Joseph, emperor of Austria, in a personal interview with Napoleon III., emperor of the French, at Villafranca, agreed to the preliminaries of a peace, stipulating for the surrender of Lombardy, as far as the line of Peschiera and Mantua, by Austria to France, the formation of a confederacy of Italian states under the presidency of the Pope, and the return of the princes who had been expelled in the course of the war from their dominions by their subjects, provided that their return was not effected by foreign intervention, but only by the will of their subjects. Of these three preliminaries only the first was ultimately ratified by the Treaty of Zurich (10 Nov. 1859). Lombardy was ceded to France, who gave it up to the king of Sardinia, in return for which the latter ceded to France, some time later, Savoy, the ancestral domain of his family, and Nice. The other two stipulations of the preliminaries of Villafranca were not carried out. So far from inviting back their banished rulers, the inhabitants of the duchies hastened to summon assemblies to pronounce their deposition, and to annex themselves to Sardinia. Even Bologna withdrew from the papal rule, and put itself under the protection of Victor Emmanuel. In March 1860, popular votes were taken in Savoy, Nice, Tuscany, Parma, Modena, and the four northern papal legations constituting Romagna, in virtue of which the cession of the first two to France was carried into effect, and the remainder were incorporated in the kingdom of Sardinia. Neither the protests of Switzerland against the surrender of the districts on the south of the Lake of Geneva, nor the ban of excommunication pronounced by the Pope on the chief actors in these events, could prevent them from taking their course. Meanwhile the victorious career of Garibaldi in Sicily and lower Italy had led to the dethronement of the king of Naples, and the detachment of the provinces of Umbria, Urbino, and the Marshes, with Benevento and Pontecorvo, enclosed by the kingdom of Naples, from the states of the Church; and Sardinia intervening to complete the revolution, the whole of Italy and Sicily, except Rome and its vicinity and Venetia, was combined in a united realm, which, in 1861, was proclaimed as the kingdom of Italy, with Victor Emmanuel as its sovereign, the temporal power of the Pope being secured by French troops stationed in Rome. In the war which broke out in the spring of 1866 between Prussia and Italy combined on the one side, and Austria on the other, the Italian invasion of Venetia was repulsed in the battle of Custoza 24 June; but the Austrians, suffering heavy reverses from the Prussians, ceded Venetia to the emperor of France, by whom its destiny was put to the vote of its inhabitants. Their vote being in favor of union with Italy, the province was accordingly joined to it. There was still one part of the Italian territory not included in the kingdom of Italy, namely, the Papal States, where the Pope continued to maintain his temporal authority under the protection of French troops. According to a convention concluded between France and Italy, 15 Sept. 1864, these troops were to be withdrawn in the course of the year 1866. This was, indeed, actually done, but their place was taken by a corps levied in France and commanded by the French general Dumont, whom

Napoleon sent in July 1867 for the purpose. The protestations of the Italian government were of no avail, but on the outbreak of the Franco-German war the French troops were withdrawn, and after the fall of the empire in consequence of the defeat at Sedan, the Italian government could no longer resist the demands of the press and of popular feeling, and occupied the Papal States (September 1870), soon after which they were annexed to the kingdom of Italy. While the Pope was deprived of his temporal dominions, his spiritual independence was guaranteed. In 1871 the seat of government was removed to Rome from Florence (having until 1865 been at Turin). In 1878 Victor Emmanuel, the first king of united Italy, died, and was succeeded by his son Humbert. The acquisition of territory in Africa was pursued with vigor from 1880 until 1896, when a conflict with Abyssinia and a severe defeat of the Italian troops at Adowa checked colonial enterprise. Humbert was assassinated in 1900 and was succeeded by his son Victor Emmanuel III. Italy, with Germany and Austria-Hungary, form the Triple Alliance, having in view the preservation of the peace of Europe.

Language.—Ancient Italy is supposed to have had a common language of many dialects. That which is common in all these dialects is the heirloom of the Indo-European stem; while that in which they differ either belongs to other stems of languages, or is of later origin. Leonardo Bruni (15th century), Cardinal Bembo ('Prose, nelle quali si ragiona della volgar lingua,' Venice, 1525), Saverio Quadrio, etc., assert that it is as ancient as the Latin; that both were used in Rome, the Latin in public speeches, in legal documents, and by the learned, while the *Romanus rustica* was spoken by the people and in private conversation. The Latin, having been Grecized, became so to speak, stereotyped and sterile, and died away with the aristocracy; whereas the vulgar speech, carelessly spoken, and poor in grammatical forms, continued to live. Ciampi traces the use of the language to the 5th century. Gonzo (about 960) attests its use among the better educated portion of the inhabitants; and Wittekind mentions that the emperor Otho I. (936-73) spoke both the *lingua Romana* and the *lingua Slavonica*. Pope Gregory V. (996) instructed the people in the same. The opinion, therefore, that the Italian was formed as late as the 11th century, is groundless. In the 13th century the Italian improved rapidly in pliability, elegance, and soon also in regularity, so that in grammar and lexicology it approached in the 14th very much the form it has now. With the exception of the Icelandic, all other modern European languages were yet in their infancy. Dante did most of all toward developing and consolidating the native elements, in legitimizing the exotic accessions, and in polishing the whole language, which he calls *illustre*. Petrarch (died 1374) and Boccaccio (1375) rendered Dante's idiom more mellow and popular; the former by imparting to it the polished suppleness of the Provençal, the latter by emboldening it to express all shades of thought.

Little was done in promoting the language in the 15th century, but the 16th endowed it with choice terms of art, in consequence of antiquarian researches. Nicolo Macchiavelli (1469-1527) was

ITALY

the father of Italian prose. Pietro Bembo (died 1547), Giovanni Ruccellai (1526), Jacopo San-nazaro (1530), G. G. Trissino (1550), Ariosto, Tasso, Guarini, etc., raised it above all other European languages. Aug. Beolco di Ruzzante (Venice, 1565) wrote six comedies, in which each person speaks his native dialect; a method analogous to the use of Prakrit in Indian dramas. Benedetto Varchi ('L'Ercolano,' etc., Florence, 1570) reformed the orthography and established the grammar. Grazzini with Leonardo Salviati founded, in the *accademia della crusca* at Florence, a tribunal of the language (1582). The influence of French on European languages during the 17th century began to be exerted on the Italian, especially on its syntax. Algarotti was the chief fosterer of this influence. But Monti ('Correzioni al vocabolario della crusca,' and in other works) and Perticari strenuously and successfully resisted this denationalization, and restored to their cherished tongue the glorious direction imparted to it in the 14th century. The area of the Italian language comprehends the whole peninsula and the islands of Sicily, Sardinia, Corsica, etc.; the Swiss canton of Ticino, and parts of the Grisons and Valais; South Tyrol, some cities of Istria and of Dalmatia, and partly the Ionian islands. A rough idiom of Mediterranean navigators, and a jargon known as the *lingua franca*, are spoken in the Levant. Dante's *parlare illustre* (also *cardinale, aulico, cortigiano*) is common to all well educated Italians. Many of the dialects differ as much from it as it differs from Spanish, and some even more. This is owing to the ancient local varieties of the *Romana rustica* and of others, as well as to the tongues of foreign invaders. Dante ('De Vulgari Eloquio') speaks of 14 dialects, one class on the west, the other on the east of the Apennines. Those on the north approach the Provençal language.

Literature.—The Italian language molded into a peculiar shape, different from the Latin, and free from most of the rough and uncouth words and phrases which the invading hordes of northern barbarians had introduced into it, the Emperor Frederic II, who resided in Palermo till the commencement of his reign in 1212, made the language of his court. He gathered there many men who delighted in composing verses, and founded the university of Naples, and schools in Palermo and other Sicilian cities. More celebrated as a poet than either himself or his two sons, Enzio and Manfred, was his secretary Pietro delle Vigne, who was wont to go about singing his songs in the newly formed language, some of which have been preserved and are deserving of praise. From Sicily the taste for literature seems to have spread to other parts of Italy. Foremost among the succeeding authors were the Bolognese Guido Giuncelli (died in 1762), mentioned most honorably by Dante in many of his works, Guido Ghislieri, Fabricio, and Onesto. In Tuscany also appeared Guittone d'Arezzo (died in 1294), Bonagiunta da Lucca, Gallo Pisano, Mino Macato Sanese, Brunetto Fiorentino, and others. Several sonnets and songs of Fra Guittone are preserved, and also 40 letters to a friend, the oldest specimen of the epistolary style in Italian. Dante criticises his compositions as languid and unimpassioned.

Brunetto Latini (about 1260) was the teacher of Dante and the author of 'Il Tesoro,' written first in French and afterward translated into Italian, in which he aimed to give a cyclopædic view of the state of knowledge at that time. He also wrote the 'Tesoretto,' consisting of moral sentences in seven-syllabled rhyming couplets. Guido Cavalcanti (died in 1300), one of the best friends of Dante, was styled by Benvenuto da Imola the second eye of Italian literature, of which Dante was the first. He was a philosophic poet, and his verses gave him a reputation for learning, and show that he had a deep knowledge of human heart and was accustomed to moral reflections. The first book in Italian prose was the 'Chronica' by Matteo Spinnolo, a Neapolitan, relating the history of events from 1247-68. The honor of writing history in a neat style belongs also to Ricordano Malespini, a Florentine, who died about 1281. The 'Agricoltura' and other scientific works of Pietro Crescenzi, a Bolognese, show in several respects a thorough knowledge: but in attempting to explain vegetation and other natural phenomena after the theories of Aristotle, he fell into the errors prevalent in his age. In the 13th century began the glorious literary era of Dante, Petrarch, and Boccaccio. Dante (1265-1321) rose like a sun, and shone on Italy with an unparalleled splendor, giving to that nation almost a new life. He raised the language from comparative rudeness to the highest refinement, conceived a poem which is admitted to be one of the sublimest creations of the human mind, and charmed a people yet groping in ignorance and barbarism by the sweetness, beauty, and grandeur of his delineations, compelled them to listen to the dictates of morality and Christianity, and proclaimed the principles from which alone they could hope for rest from the desolation of civil wars. Involved in the intestine discords between the Guelfs and Ghibellines and the parties *dei bianchi* and *dei neri*, his works bear the impress not only of the ideas but of the conflicts of his time. His masterpiece is the 'Divina Commedia,' incomparably the greatest of Italian epics. It was so called because he conceived that there were three kinds of style, the sublime, the middle or comic, and the lowest of all, which he called the elegiac, and he selected the second of these for his poem. Even in this finest product of his genius he supported the emperor and the Ghibelline party against their enemies the Guelfs. He depicted an inferno in which were placed those petty tyrants and chieftains who had filled Italy with the horrors of civil war. He described a purgatory in which those men were punished who with too little heroism and firmness had maintained the cause of justice and their country. He finally pictured a paradise in which those were rewarded who had devoted themselves only to virtue, and had labored for the commonwealth with strong hearts and magnanimous deeds. There he imagined a throne to be raised, and a crown upon it, as a reward for that Henry who, he hoped, would restore Italy to her ancient power and splendor. This political aim of the 'Divina Commedia' was only incidental to its moral and religious meanings. The work displays an immense amount of theological as well as philosophical and historical knowledge, and contains some ingenious scientific

ITALY

views, which were fully developed and understood only after several centuries. It is for these that Redi, Magalotti, and other scientific writers quoted from him in preference to any other poet. The unfinished 'Convito' of Dante is called by Monti the first sound and sober prose writing that Italian literature can boast, and the first on moral philosophy. Dante abandoned the Latin language, in which he had begun to write, for the Italian, the perfection and embellishment of which he deemed would be of great advantage toward uniting Italy. In his Latin treatise 'De Vulgari Eloquio' he maintained that no one of the Italian dialects merited the name of the Italian language, which was rather the language spoken in all the cities, without belonging to any one in particular. Francesco Stabile, called also Cecco d'Ascoli (burned for heresy at Florence in 1327), wrote the 'Acerba,' a witty poem, directed against Dante and Guido Cavalcanti, and treating of natural and philosophical subjects with little wisdom or eloquence. It is in strophes of eight verses, the last two rhyming, and some have therefore ascribed to him the honor of inventing the *ottava rima*. More highly esteemed was Fazio Bonifazio degli Uberti (about 1367), who wrote in *terza rima* the long allegorical poem of 'Dittamondo' (*Dicia Mundi*). Cino da Pistoja (1270-1336) excelled both in jurisprudence and poetry. His songs were in praise of Selvaggia, a lady of whom he was enamored, but his legal work 'Il comento' is of greater importance, and displayed an erudition which gained him invitations to lecture in many universities. Dante commended him as an improver of the language, and Petrarch lamented his death in touching verses. Petrarch (1304-74) had seen Laura de Sade at Avignon, who was the inspiration of the charming verses to which he owes his immortality, and had produced his Latin poem of 'Africa,' on which by a strange misjudgment he chiefly prided himself, when in 1341 he received the laureate crown in Rome. The noble delicacy and tenderness of affection which make him so distinctively the poet of love were hardly his principal merits. All men who honor and cherish learning and patriotism, revere his name, who left as an heritage the precept and example of seeking to end the intestine discords of his country by elevating it to a worthier life. His principal philosophical treatises and poems, in Latin, demonstrate his erudition, justness of philosophical thought and sentiment, and exquisite skill in Latin composition. He has a greater celebrity as the father of Italian lyric poetry. In this department he surpassed all his predecessors, and has been equaled by none of his numerous successors and imitators. A less versatile author was Giovanni Boccaccio (1313-75), who abandoned successively commerce and law for literature, studied with ardor the 'Divina Commedia,' and cherished the friendship of Petrarch. He wrote several works in Latin, and made an expensive collection of Greek manuscripts, but is chiefly known as the author of the 'Decamerone,' and thereby as the father of Italian prose. The 'Decamerone' (ten days) is so called because each of the 10 persons introduced into it, seven ladies and three young men, relates 10 stories per day, 100 stories being thus told in 10 days. The scene is a villa in the vicinity of Florence, whither

they had fled from the plague (1348), and the description of that pestilence with which the work opens is admired as a masterpiece of eloquence. Its real object seems to have been to present a picture of the whole human family, and to encourage virtue by commendation and to correct vice by ridicule. Its beauty of composition is, however, sometimes expended on the most indelicate subjects. The 'Cento novelle antiche' are for the most part written from those of Boccaccio, but some are of earlier date. They relate short adventures in a graceful and simple style, free from indelicacy. Franco Sacchetti of Florence left 300 tales, of which 258 are preserved, written carelessly but with great purity. The 'Pecorone' of the Florentine Ser Giovanni, an imitation of the 'Decamerone,' contains about 50 tales. This was the age of chroniclers as well as novelists. Dino Compagni chronicled the history of Florence from 1270 to 1312 with truthfulness and elegance. More celebrated is the work of Giovanni Villani, containing the history of the city from its foundation till a few years before his own death by the plague in 1348. His work was continued with greater prolixity by his brother Matteo to 1363, when he also fell a victim to the plague; and to 1364 by Filippo the son of the latter, who also wrote a series of biographies of illustrious Florentines. The 'Specchio della vera penitenza' of Giacopo Passavanti (died in 1357) is the first example of an ascetic work in the vulgar tongue, and its style is comparable for excellence with that of Boccaccio. Various similar treatises were written by Domenico Cavalea of Pisa; the 'Ammaestramenti degli antichi,' by Bartolomeo da S. Concordio, merits particular praise; and the 'Trattato del governo della famiglia,' by Agnolo Pandolfini (1365-1446), is equally esteemed for its happy and useful choice of materials, and for its natural and graceful style, adorned with all the skill which the writers of his age may boast. Most of the men who flourished in the 14th and 15th centuries were not distinguished like Dante and Petrarch for creative genius, but delighted rather in reproducing and commenting on the authors of antiquity. The printing-press, invented in Germany, was most usefully employed in Venice, Bologna, and Rome, in multiplying copies of the ancient authors, corrected by learned scholars. To the passion for discovering and publishing new manuscripts was joined that of finding and interpreting ancient monuments, medals, inscriptions, and sculptures. Only the first steps toward a new civilization had been taken by Petrarch and Boccaccio. The introduction of the mariner's needle by Flavio Gioja had opened the ocean to the Europeans; the travels of Marco Polo had awakened that curiosity concerning the way to the East Indies which led Columbus to the discovery of the new world; the Arabic numerals had been substituted in Italy for the Roman; academies were established to nurture the love of letters, and courts became an asylum for the most distinguished men; and the popes in Rome, the Medici in Florence, the houses of the Visconti and the Sforzas in Milan, and of the Gonzagas and Estes in Mantua and Ferrara, became protectors of literature and the arts. Pope Nicholas V. is especially distinguished for the encouragement which he gave to every branch of learning, and for the generous sacrifices which he made in col-

ITALY

lecting books. It was under his liberal protection that Francesco Filelfo translated the 'Iliad' and the 'Odyssey' into Latin verse. His example was followed by numerous courts in Italy. Lodovico invited to his court in Lombardy many learned men, painters, and architects, among whom were Leonardo da Vinci and Bramante, founded the university of Pavia, granting it many privileges, and opened schools in Milan, to which most renowned professors gave distinction. But the most illustrious of the patrons of letters was Cosmo de' Medici. He founded one library in Venice and three in Florence, and established the first academy for the study and promulgation of the Platonic philosophy. Pico della Mirandola and Cristoforo Landino exercised the happiest influence in advancing and creating a popular esteem for knowledge, and especially in exciting the Florentine youth to an enthusiasm for it. The former was almost unrivaled in erudition, and seemed to possess a miraculous memory, being profoundly and prematurely versed in numerous languages, in metaphysics, and in mathematics. Lorenzo de' Medici (died in 1498) greatly and variously increased the glory which his uncle had acquired in the culture of learning. But it is lamentable, after the three great masters of the Italian tongue which the preceding age had presented, that the taste of the learned returned to the Latin language. To such a degree was Italian neglected, that it was hardly used at all in writing; it was even disdained for legal documents, and its development was arrested by a boundless reverence for antiquity. But Lorenzo the Magnificent may be considered the reviver of Italian literature, and was even called its father. Most esteemed for his virtues and manners, he enriched libraries, reopened the university of Pisa, collected numerous remains of antiquity, promoted the study of the popular poetry, and wrote himself many admired pieces for the improvement of the public taste. His 'Nencia da Barberino' is the first example of Italian rustic poetry, and his 'Compagnia del Mantellaccio' seems to have given the first idea of Italian satire in *terza rima*. Under him Florence became a new Athens. Angelo Poliziano (1454-94) enjoyed the friendship of Lorenzo, attained to great erudition, and was an elegant writer both in Italian and Latin. His most celebrated works are the 'Stanze,' which were imitated even by Ariosto and Tasso, and the 'Orfeo,' the first regular and consistent Italian drama. Contemporary poets of less note were Burchiello, Girolamo Benivieni, and Giusto de' Conti. To the various kinds of composition which have thus far appeared must now be added some epics. Of the brothers Bernardo, Luca, and Luigi Pulci, only the last (1431-87) achieved lasting eminence in poetry. His 'Morgante Maggiore,' burlesque and fantastic, opens the brilliant Italian series of romantic poems of chivalry. It belongs to the circle of legends concerning Charlemagne and his paladins, but degrades the primitive simple faith in them by persiflage. The 'Mambriano' of Cieco da Ferrara deserves to be mentioned and compared with the 'Morgante.' The best of the romantic poems of the 15th century is the 'Orlando innamorato' of Boiardo, which introduced materials so beautiful and so vast as to induce Ari-

osto to follow in the same path. To sustain the marvels of his subject, he employed magicians and fairies in connection with the classic divinities, and beneath the veil of poetry he represented the most useful truths of philosophy. The 'Orlando innamorato' was left incomplete, and the original has become rare even in Italy, on account of its rude and antique diction. Its tone is much modified in the elegant elaboration of it by Berni, which has enjoyed the most general favor. The prose literature was enriched by the writings of two artists: Leon Battista Alberti, the author of a dialogue 'Della famiglia,' containing philosophical precepts for domestic life and the education of children, and of treatises on painting and architecture which gained him the name of the Italian Vitruvius; and the renowned Leonardo da Vinci (1452-1519), at once painter, sculptor, architect, mathematician, musician, the best extemporeous poet of his time, and the author of a 'Trattato della pittura,' which reveals both his scientific and artistic knowledge, and is a classical authority on the use of terms pertaining to the arts and sciences. Numerous historians, also, belong to this age. Pandolfo Collenuccio was the first to write an esteemed history of the kingdom of Naples, revived and corrected the taste for comedy, founded the first museum of natural history in Europe, and wrote dialogues after the manner of Lucian, and the solemn poem of 'Inno alla morte.' Historians of travels were the Genoese Giorgio Interiano and the Venetian Cadamosto, who give the oldest narratives of the Portuguese discoveries, and the Florentine Amerigo Vespucci. Aldo Manuzio (Aldus Manutius) rendered signal services to letters, and gained a European repute by the care and taste with which he published the classics. The 16th century, in respect of Italian art and literature, is surpassed by none in modern history, and rivals the ages of Pericles and Augustus in antiquity. A family of great names occurs, each of which might form an epoch. Leo X. was the most illustrious of a series of papal patrons, bestowing liberal rewards not only on authors but on Raphael and Michelangelo. After the extinction of Florentine liberty, literature was again protected by various reigning families. Cosmo de' Medici commanded Varchi to write his history without any regard to persons, and we therefore owe to him a narrative of the crimes by which his own family attained the sovereignty. Under his son Francesco the learned institutions already in existence were advanced, and the academy *della crusca* was founded. The court of the Estes in Ferrara entertained Ariosto and Tasso; most of the other courts, great and small, as those of the Gonzagas in Mantua, of the dukes of Urbino, and of Manuel Philibert of Savoy, were hospitable to scholars and poets; and numerous literary academies with capricious names, as those *dei sonnacchiosi*, *degli storditi*, and *dei selvaggi*, were instituted. Pre-eminent among the poets of the age rose Ariosto (1474-1533), called the Ferrarese Homer, who aimed to celebrate in a great poem the origin of the house of Este. The loves and exploits of Bradamante and Ruggiero, imaginary ancestors of that house, form the basis of his romantic epic, the 'Orlando furioso,' the subject of which is the war of the Saracens against Charlemagne. The courtesies and hero-

ITALY

isms of knights, the loves of ladies, and the madness of Orlando give occasion for most various and always natural pictures, all the passions being delineated in appropriate colors, so that Tasso affirmed the excellence of Ariosto not only in versatility of invention but in propriety of treatment. Many of his similes are unsurpassed in simplicity and grace. Beside his masterpiece, he wrote satires on the politics and the rulers of his time, and his 'Negromante' and 'Zanotti' almost entitle him to be called the father of Italian comedy. Bernardo Tasso, the father of Torquato, was the author of the 'Amadigi' and other esteemed poems. His more renowned son (1544-95) strictly followed Virgil and Homer in the form of his 'Gerusalemme liberata,' but its finest ornaments belong to the romantic spirit of his age. To the classical mythology it adds the marvels of enchantment and magic. The greater merits of the 'Gerusalemme' have caused his 'Rinaldo' and his pastoral drama of 'Aminta' to fall into undeserved neglect. Some of his sonnets also, and other minor pieces, possess a rare beauty; and his prose letters and moral dialogues are remarkable for their eloquence and philosophical tone. Inferior to the epics of these great masters are the 'Girone il cortese,' treating the legends of King Arthur, and the 'Avarchide,' describing the siege of Bourges, by Alamanni, who also wrote the 'Coltivazione,' a specimen of monotonous harmony. Rucellai is the author of a short and carefully finished didactic poem, entitled 'Le api.' Valvagone wrote in the 'Angelede' a description of the battle between the good and rebel angels, from which Milton is supposed to have derived materials. The 'Italia liberata dei Goti,' by Trissino, is in every respect a wretched imitation of Homer; but his 'Sofonisba' is the first Italian tragedy of high merit. Leo X. himself witnessed the production of the 'Rosmunda' and the 'Oreste' of Rucellai. Better tragedies are the 'Tullia' of Martelli, the 'Canace' of Sperone Speroni, the 'Torrismondo' of Torquato Tasso, and the 'Epido' of Andrea dell' Anguillara, all of which display a too servile imitation of the Greek authors. The Latin comedy, meantime, was made too strictly the model of the Italian. The learned comedy (*commedia erudita*) was cultivated at almost the same time by Cardinal Bibbiena, Ariosto, and Macchiavelli. The best examples are the 'Cassaria' and 'Suppositi' of Ariosto, the 'Calandra' of Bibbiena, and the 'Madragola' and 'Clizia' of Macchiavelli, the last especially remarkable for their knowledge of men. The 'Pastor fido' of Guarini deserves especial mention as one of the pastoral poems with which Italy abounded, inferior at furthest only to the 'Aminta' of Tasso. At this period a new and brilliant step was taken by the Italians in the dramatic art, by the union of music with poetry. The invention of the opera belongs to the Florentines, the first having been the 'Daphne,' the words of which were by Rinuccini and the music by Peri, and which was represented in 1597. Orazio Vecchio of Modena produced melodramas, which Maturatori regards as the beginning of the modern opera. The attraction of this new style was so great that authors and musicians immediately devoted themselves to it in Italy, and it was soon introduced into Germany and France. Every variety of poetry seems to have been tried in

this age with success. Berni was the head of a school of burlesque poetry, called from him the Bernesca rhyme. The best of his pieces, the 'Orlando innamorato,' possesses grace, elegance, and originality. One of his imitators was Agnolo Firenzuola, who is more esteemed for the amenity of his prose writings. To Ariosto belongs the first place among the satirical as well as romantic poets of his age. Scarcely comparable with him are the satirists Ercole Bentivoglio, Nelli, and Luigi Alamanni. Pietro Aretino (1492-1557), the most indelicate of Italian writers, evinced a versatile and brilliant genius in almost every style of composition. The monk Folengo (died in 1544), better known under the name of Merlino Coccajo, was either the inventor or one of the first and happiest improvers of macaronic poetry. Superior to a crowd of rhymers, imitators of the ancients or of Petrarch, was the sculptor Michelangelo, whose style was influenced by the study of Dante. Pietro Bembo (died in 1547) was the restorer of elegance and correctness to the native language, and revived its popularity among the learned. Francesco Maria Molza excelled in thoughtful and humorous poetry. The 'Galateo' and other writings in prose and verse of Giovanni della Casa are still esteemed for vigor of thought and beauty of expression. The translations of many of the classics into Italian by Annibale Caro (1507-66) are accounted by some critics superior in style even to the compositions of Petrarch. His versions have an air of originality, and it was said that Virgil would hesitate whether to give the palm to his own work or to that of his translator. His original writings obtained the highest praise for elegance. The sonnets of Angelo di Costanzo have been said to combine every merit of which the sonnet is capable. He wrote also a history of Naples. The most eminent poetess of this age was Vittoria Colonna, highly applauded by Ariosto. The 'Arcadia' of Sannazaro holds the first rank among the bucolics, written in alternate prose and verse in a vigorous, correct, but constrained style. The eclogues of Baldi are philosophical maxims versified. An important place in the literature is held by political writers, foremost among whom was Macchiavelli (1469-1527). A dramatist and historian of Florence, he is chiefly known as a profound and philosophical statesman by his discourses on Livy, his dialogues on the art of war, and especially by his 'Principe,' a manual of government, which was constantly in the hands of such sovereigns as Charles V. and Sixtus V., and the real intent and character of which has been long in dispute. His style is marked by simplicity, strength, thought, and a rare but felicitous use of ornament. Other political writings were the 'Ragione di stato' of Botero, and the 'Repubblica Fiorentina' of Giannotti. Nearer to Macchiavelli in merit was Paruta (1540-98), the author of 'Discorsi politici,' and of a treatise 'Della perfezione della vita civile.' The most renowned of Italian historians is Guicciardini (1482-1540), whose work embraces the period from 1494 to 1534. It is esteemed for impartiality and for its moral and political reflections, but is so diffuse and tedious that it is hard to read. Paolo Giovio wrote in Latin a partisan history of his own time. Historians of Florence were Nardi, Varchi, Nerli, Segni, Capponi, and Scip-

ITALY

ione Ammirato; the 'Storie Fiorentine' of the last includes the events from the foundation of the city to 1574. Historians of Venice were Bembo, Paruta, and Contarini; of Genoa, Giustiniani, Bonfadio, and Foglietta; of Ferrara, Cinzio and Falletti; and of Naples, Costanzo, Porzio ('La congiuro dei baroni,' etc.), and Summonte. General histories were written by Giambullari and Adriani. Davanzati translated Tacitus to prove the conciseness and energy of the Italian language, and made his version shorter than the original. He also wrote a history of the reformation in England. The splendor of the fine arts in this century gave occasion for historians of art, the principal of whom was Vasari (1512-74), whose lives of the most excellent painters, sculptors, and architects of Italy are written with naturalness and grace, and contain interesting notices of prominent Italian works of art. The autobiography of the Florentine goldsmith Benvenuto Cellini, one of the liveliest books in the literature, not only recounts his own fortunes, but gives curious notices of the courts of Rome, Florence, and France. He wrote also valuable treatises on jewelry and sculpture. Works on painting were written by Bernardino Campi of Cremona, Lomazzi of Milan, and Armenino of Faenza. Vignola and Palladio gained distinction as writers on architecture, and Marchi by a treatise on military architecture. Philosophy now began to assume an independence of the scholastic and ecclesiastical systems, and Girolamo Cardan and Giordano Bruno ventured upon the boldest speculations. The mathematics were cultivated by Tartaglia, Cardan, and others. The 'Institutione di tutta la vita dell'uomo' of Alessandro Piccolomini treats of education, marriage, the government of a family, and the chief end of man. The 'Cortigiano' of Castiglione has rare literary merits, making courtesy the theme of many learned and weighty reflections. Numerous novelists now flourished, among whom Bandello holds the first rank, his *novelle* being chiefly founded on real and common events. The novels of the monk Firenzuola and the 'Cene' of Lasca are both elegant and indelicate. Vettori and Salviati commented on the older poets, and the latter was engaged in compiling the 'Vocabolario della Crusca,' then the most important philological work in the language. All words not used by the great Forentine authors were excluded from it; even Tasso was not admitted as an authority. In the 17th century the natural sciences especially flourished. Under able patrons, the principal of whom was Duke Ferdinand of Tuscany, the Italian universities attained unprecedented celebrity. Scientific academies were founded in Rome, Florence, Bologna, and Naples; the Florentine *accademia del cimento* embraced the most illustrious savants of the time, and published important accounts of its researches. Preeminent among philosophers was Galileo (1564-1642), who was denounced as an innovator, and maintained the Copernican system only at his peril. His 'Diagnosi' and other works are written with elegance, his style and taste having been formed by reading Ariosto. His most noted pupils were Viviani, Torricelli, and Castelli, and contemporary physicists were Borelli, Malpighi, Bellini, and Francesco Redi. The learned and philosophical jurisconsult Vincenzo Gravina at-

tracted scholars from all parts of Europe to his lectures in Rome on public law, contained in his 'L'origine de diritto civile,' and other publications. The greatest historians were Sarpi, Davila, Bentivoglio, and Pallavicini. Sarpi (died in 1623), the defender of the republic of Venice in its contest with the Holy See, wrote an anti-papal and spirited history of the Council of Trent, which was replied to by Pallavicini in a work on the same subject. Davila, after 16 years' residence in France, narrated the civil wars of that country in a work esteemed for its truthfulness, and in respect of style one of the best Italian histories. Bentivoglio, the papal nuncio in Flanders, wrote of the Flemish wars of his time, many of the heroes of which he knew personally. Baldinucci, Dati, and Scamozzi were historians of the fine arts, and Cinelli and Boccalini of literature, while Bianchi treated important historical problems as to migrations, colonics, voyages, and the origin of monarchies and republics. Montecucculi, the military antagonist of Turenne, acquired distinction as an author by his aphorisms on the art of war. The Jesuit Bartoli wrote the history of his Society, and the sermons of the Jesuit Segneri were unrivaled in eloquence. The first Italian literary journal, the 'Giornale de' letterati,' was established in Rome in 1668. A want of naturalness and truthfulness marked the poetry of the age. External delineations, trifling details, conceits, and plays upon words were the leading objects of the poets. At their head was Marini of Naples (died in 1625), who was admired not only in Italy but in France and Spain, and originated the poetical school of the Marinists, by which only his faults were imitated. Among his contemporaries and successors were Chiabrera, Guidi, Tassoni, and Marchetti. The foundation of the academy of Arcadians in Rome in 1690 by Crescimbini and Gravina introduced an affectation of pastoral sentiments and habits in place of Marinism. Menzini, Zappi, Maggi, De Lemene, Salvator Rosa, and Bracciolini wrote satirical, erotic, and facetious verses. Throughout the 17th and 18th centuries the opera was the favorite Italian exhibition. It had long been produced with theatrical and musical splendor, when Zeni of Venice (died in 1750), and especially Metastasio (died in 1782), wrote operatic plays having remarkable poetical merits. When near the beginning of the 18th century the war of the Spanish Succession raged in Italy, and the kingdom of Naples fell beneath the sceptre of the infante Don Carlos, and afterward of Ferdinand III., literature and the sciences were cultivated with renewed vigor. Naples produced Giannone, distinguished in the department of history, Capasso in literature, Cirillo in medicine, Mazochi in archaeology, Genovesi in political economy, one Gagliani in architecture, and another in domestic economy and philology. Filangieri rivaled Montesquieu in the philosophy of legislation; Pagano wrote on the criminal law; Poli distinguished himself in the positive sciences; Maffei and Calsabigi devoted themselves to poetry. The university of Bologna was now in its splendor, its academy of sciences taking the name of "The Institute." Marsigli, Stratico, Cesaretti, Foscarini, the brothers Gozzi, Morelli, Maffei, Pompei, Lorenzi, Mazzuchelli, and Serassi made the city of Venice illustrious; but political jealousy prevented the culture of the

ITALY

economical and legislative sciences there, which under Beccaria and others were making great progress in other parts of Italy. In Tuscany, the famous French Encyclopædia was republished. In the cities of Lombardy flourished Scopoli, Fontana, Frank, Tissot, Spallanzani, Bertola, Villa, Natali, Volta, Scarpa, Tamburini, Parini, Beccaria, Verri, Landriani, Agnesi, Carli, and others devoted to literature, art, science, and the development of political and ethical principles. Bodoni raised the art of typography to an admirable elegance. Prominent among the patrons of literature was Victor Amadeus II. of Savoy. The Italian drama had as yet attained to excellence only in the opera, and lacked superior tragedies and comedies. It received an impulse in the 17th century from the French theatre, Martelli of Bologna (died in 1727) being the first who attempted to naturalize not only the French tragedy but the Alexandrine verse. The 'Merope' of Maffei was the best tragedy produced in the early part of the century. A greater influence was exerted upon his age and upon literature by Alfieri (1749-1803), the head of an important school of tragedy. He was the poet of energetic action and profound thought and feeling, as Metastasio was of love. Abandoning the customs of the court of Louis XIV, he revived the simple sublimity of the Greek stage, which had been the object of his favorite studies, and which was removed alike from French effeminacy and Spanish extravagance. A reformation in the Italian comedy was meantime effected by Goldoni (1707-93), the only genuine comic poet that Italy can boast, who sought in imitation of Molière to substitute for the *commedia dell' arte* a natural comedy of manners. In his efforts to give to the stage a more human and real character by ridding it of the traditional masks of the harlequin, pantaloon, and other stock characters, he had to contend especially against Chiari and Carlo Gozzi. The example of Kotzebue and Iffland gave rise to a lachrymose school of dramatic composition, maintained by Avelloni, Gualzetti, Greppi, and especially by Federici. The most illustrious historians were Muratori (died in 1750), Maffei, Denina, Mazzucchelli, Tiraboschi, and Lanzi (died in 1810). The 'Annali d'Italia,' 'Verona illustrata,' 'Revoluzioni d'Italia,' 'Scrittori d'Italia,' 'Storia della letteratura d'Italia,' and the 'Storia pittorica d'Italia' were respectively their best works. The writings of Muratori and Tiraboschi still maintain their reputation both for erudition and criticism. In archaeology, the names of Fabretti, Gori, Mazzocchi, Martorelli, Passeri, and Carli were distinguished. Campanella continued the philosophical movement of Bruno in opposition to scholasticism, and Vico (1690-1744) founded the new science of the philosophy of history. His 'Scienza nuova' is a view of general history, founded on the idea of Divine Providence and the essential elements of the common nature of man. Algarotti, Bettinelli, Buonafede, Vantetti, Tartarotti, and Alessandro Verri also added to the glory of the literature by abandoning the pedantic style that had been in vogue and introducing an acquaintance with foreign ideas and productions. Baretti contributed to the revival of good taste by ridiculing the Arcadians. Parini (1720-99) excelled in satirical poetry, his 'Giorno' being as remarkable for elegance

as for severity upon the effeminate life of the wealthy Milanese nobles. Among the works of Cesaretti was a translation of Ossian, esteemed in many respects among the happiest productions in the language, and which Alfieri confessed had been of service to him in the composition of his tragedies. The political and military movements in Europe of the last decade of the 18th century occasioned a regeneration not only of the literature but of the national spirit of the Italians. The early part of the 19th century rivals the age of Leo X., presenting Canova, Longhi, Cicognara, Appiani, and Beltrami in the fine arts; Monti, Foscolo, Pindemonte (partially contemporary with whom was Alfieri) in literature; and Volta, Melchiorre Gioja, Romagnosi, Scarpa, Spallanzani, and Oriani in the sciences. The author who doubtless exerted the greatest influence on the regeneration of poetry was Vincenzo Monti (1754-1828), who in the contest between the classic and the romantic tendencies favored the former, and in the contest between the Gallicists, or imitators of the French literature and idioms, and the Purists, who made Petrarch, Dante, and the other old Italian masters their models, sided with the latter. His poems, as 'Basilliana' and 'Feroniade,' his tragedies, as 'Galeotto Manfredi,' his elegy 'Mascheroniana,' the 'Proposta,' in which he disputed the restrictions which the Della Cruscani had fastened upon the language, and his translation of the 'Iliad' alike display an admirable and nervous style. Pindemonte also made a light and graceful version of the 'Odyssey,' and in his original poems especially lamented the desolation of his country. Ugo Foscolo (1777-1827) belongs to the school of Alfieri. His 'Ultime lettere di Jacopo Ortis,' a political and passionate romance in imitation of Goethe's 'Werther,' is supposed to describe his own troubled life. He wrote the lyric 'I sepolcri,' and other works in prose and verse, remarkable both for power and beauty. Mezzanotte celebrated in verse the struggle of the modern Greeks for liberty, regarding it not only as a political but as a religious conflict between Christianity and Islamism. The lyrical poems of Leopardi are highly esteemed. Among the epic and didactic poets were Botta, Ricci, Bagnoli, Arici, Grossi, Sestini, Pananti, and Lorenzi. Antonio Cesari (died in 1828) was the chief of the Trecentists, a school which carried its love of the Italian authors of the 14th century to affectation. Stratton published a dictionary containing only the words used by the Marinist authors. Mameli had exhibited the greatest promise in his ode to Venice, before he fell in the conflict at Rome in 1848-9. Prati, Aleardi, and the versatile priest, dramatist and journalist, Dall' Ongaro, were among the best lyric poets of Italy of the last half-century, and among contemporary lyric poets are Graf and Ada Negri. For the revival of pure and unaffected writing Italy was much indebted to the example of Carlo Botta, called by his countrymen the modern Thucydides. He wrote histories of the war of American independence and of Italy during the last three centuries. Vacani was a historian of the Peninsular war. Pietro Colletta wrote the history of Naples from its conquest by Charles III. of Spain in 1734. Amari wrote the history of the Arabs in Sicily and of the Sicilian Vespers, illustrating obscure periods in an age of national

ITALY

glory. Both were reflective or philosophical historians. Cesare Cantu wrote an immense universal history, a work of critical and artistic merit, which has been translated into several languages. He has also written novels, poems, critical essays, and other histories, one of the most important of which is 'La Storia di cento anni' (1851). Bianchi Giovini, a prominent and anti-Catholic journalist, wrote a history of the popes, a biography of Fra Paolo Sarpi, a history of the Hebrews, and a work on the supposititious Pope Joan. The political writings of Mazzini consist chiefly of articles in journals. Cesare Balbo wrote historical meditations, a life of Dante, and a summary of the history of Italy. Franscini wrote an accurate and authoritative statistical work on Switzerland (1847-51). La Farina is the author of a history of Italy from the most ancient to recent times; Federico Sclopis, of a history of Italian legislation (completed in 1857); Luigi Zeni, of an excellent compendium of Italian history; Romanin, of a learned history of Venice, written in opposition to that of Daru, and of a work on the Venetian inquisitors; Carlo Gemelli, of a history of the Belgian revolution of 1830; Giuseppe Rubini, of a history of Russia from 862 to 1725; Canette, of a history of Amadeus II. of Savoy; Canale, of a history of the Crimean war of 1854-5; Gallegna, of a history of Piedmont; Angelo Brofferio, of a history of Piedmont from 1814 to 1849, and of other works interesting from their patriotic spirit as well as literary merit; Anelli, of a history of Italy from 1814 to 1850; Carlo Catteneo, of a history of the insurrection at Milan in 1848 (he was a member of the committee that directed the operations against the Austrian militia, and a participant in the struggle); he also compiled the 'Archivio triennale,' an elaborate and most careful and valuable collection of authentic documents relative to the events that occurred in Italy from 1848 to 1850; Federico Torre, of a history of the French expedition to Rome in 1849; Ferrari, in a work on republican federation, treated the question under what form of government Italy ought to be reorganized; L. C. Farini wrote a history of the Papal States from 1814 to 1850; Gualterio, of the last Italian revolutions (1852); Vecchio, of the events in Italy in 1848-9; among more recent historians were Giudici (1812-72), Settembrini (1813-76), and De Sanctis (1818-83). A taste for illustrating the national antiquities also arose and Inghirami published 'Monumenti Etruschi,' Delfico his 'Origini Italiche,' Fanucci his 'Storia dei Veneziani,' 'Genovesi e Pisani,' Manno his 'Storia di Sardegna,' Bres 'Malta illustrata,' and Pompeo Litta his learned 'Famiglie celebri d'Italia,' containing interesting studies on every period of the national history. Visconti (1751-1818) was distinguished in classical archaeology, and Sestini was unrivaled in numismatics, making medals illustrate geographical questions. The natural sciences were advanced by four illustrious savants, who were nearly contemporary, Volta, Galvani, Scarpa, and Spallanzani. The discussions of Galvani and Volta concerning their new discoveries in electricity divided the scientific men of Europe into two factions, and the poets followed their example. Scarpa, a learned disciple of Morgagni, reduced anatomy to a positive science. Spallanzani wrote on physics and physiology in a style worthy of one

who declared philosophy itself imperfect unless its principles were elegantly expressed. Gioja and Romagnosi treated philosophical questions and the economical and political sciences, the 'Filosofia della statistica' being the principal work of the former, and the 'Genesi del diritto penale' of the latter. Manzoni produced new models of lyric verse, and examples of historical dramas and novels in his 'Adelchi,' 'Il conte di Carmagnola,' and 'I promessi sposi.' To the modified classical school of Monti belong the dramas of Silvio Pellico, chiefly known by his 'Francesco da Rimini' and 'Le mie prigioni,' and those of Nicolini, often founded on the history of his country, and strongly marked by patriotic feeling. The example of Sir Walter Scott in the production of historical romances had many followers in Italy. 'I promessi sposi' of Manzoni (1825) was succeeded by the 'Monaca di Monza,' 'Luisa Strozzi,' and 'Il conte Ugolino della Gerardesca' of Rosini; the 'Margherita Pusterla' of Cesare Cantu; the 'Marco Visconti' of Grossi; the 'Ettore Fieramosca' of Azeglio; and the 'Battaglia di Benvento,' 'Assedio di Firenze,' 'Isabella Orsini,' and 'Beatrice Cenci' of Guerrazzi. Italy received with enthusiasm these romantic delineations from her ancient history. The romance entitled 'Famiglia' (1850), by Bersezio, is one of the best late Italian novels. The 'Dr. Antonio' of Ruffini is esteemed for its pictures of Italian scenery. Accomplished women have taken a considerable part in recent Italian literature. The 'Morte di Adone' of Teresa Bandellini was followed by the learned philosophical and religious poems of Diodata Saluzzo, with which she intermingled slight lyrical pieces. Cecilia de Luna Foliero wrote on the education of girls and the moral influence of music. Giustina Rimier Michiel celebrated in song the festive days and commemorated events of Venice. Isabella Teotochi Albrizzi wrote a graceful and truthful biography of Canova. The work of the Signora Ferucci on the education of girls received the encomiums of Gioberti and other distinguished thinkers. Other female authors are Lucrezia Marinella, Sabina Rasori, Silvia Curtoni Verza, Costanza Moscheni, and Leonora Fonseca Pimentel. In philosophy, the names of Gioja and Romagnosi were succeeded by that of Pasquale Borelli (Lallebasche), the author of an introduction to philosophy, and of works on the nature and genesis of thought, in which he opposed the empiricism of Romagnosi. Pasquale Galuppi (1770-1846), in elaborate works, combated the philosophical tendencies of the 18th century by doctrines founded on the philosophy of the Fathers of the Church. He was a student of the German philosophers, and one of his most interesting works was on the changes of modern philosophy from Descartes to Kant. Mamiani (born in 1802) published his 'Rinnovamento dell' antica filosofia Italiana' with the design of restoring the philosophical method of the Church Fathers, which he regarded as the national philosophy of the Italians, and of reconciling the extreme conclusions of speculative philosophy with the dictates of common sense. Rosmini (1787-1855) and Gioberti (1801-52) developed ideal Catholic theories, and founded a school in which, according to Rosmini, the only necessary and innate idea is that of the possibility of being. Gioberti, a more brilliant and learned

ITALY

author, denounced psychology, and made the formula *L'ente crea le esistenze* the ontological basis of philosophy. Among contemporary literary celebrities are Annunzio, poet, dramatist and novelist; Carducci and Rapisardi, poets and critics; Cossa, Ferrari, Giacometti, Pulle ("Castelnuovo"), dramatists; De Amicis, Barrili, E. Castelnuovo, Farina, Matilde Seras, and Verga, novelists. Among modern scientific authors and critics are D'Ancona, Ascoli, Comparetti, De Gubernatis, Lombroso, Rajna, and Villari.

Art.—For *Italian Architecture* see ARCHITECTURE.

Painting and Engraving.—The 12th century is generally taken as the period of the beginning of the history of painting in Italy, but before that time it had been the scene of the labors of Greek and Byzantine artists. During the pontificate of Leo the Great (440–461) a large picture in mosaic was executed in the Basilica of St. Paul, on the road to Ostia, and the portraits of the first 42 bishops, which are seen in the same church, date their origin from the same time. Mosaic and encaustic painting was then the prevalent mode. Painting in distemper was afterward introduced. About the end of the 6th century there were many paintings which were not believed to be the work of mortal hands, but were attributed to angels or blessed spirits. To this class, called *Acheiropoietia* (not made with hands) belongs one of the most famous representations of the Savior, in wood, at Rome, of which a sight can be obtained only with difficulty, in the *sanctum sanctorum*. In the 8th century painting on glass, mosaic on a ground of gold, and painting in enamel, were zealously prosecuted in Italy. There were already many native artists. One of the oldest monuments of art is the celebrated Christ on the Cross, in the Trinity church at Florence, which existed there as early as 1003. About 1200 a Greek artist, Theophanes, founded a school of painting in Venice. The art was first pursued with zeal in Pisa. The only artist of eminence who preceded Cimabue, who was born at Florence in 1240, was Guido of Siena, whose most celebrated work is a madonna, executed in 1221 for the church of San Domenico in his native place, where it is still to be seen. Cimabue, who was regarded as a prodigy by his contemporaries, first introduced more correct proportions, and gave his figures more life and expression. His scholar Giotto (died 1336) excelled him even in these respects, and exhibited a grace hitherto unknown. He was the friend of Dante and Petrarch, and practised with equal success historical painting, mosaic, sculpture, architecture, and portrait and miniature painting. He first attempted foreshortening and a natural disposition of drapery, but his style nevertheless remained dry and stiff. Boniface VIII. invited him to Rome, where he painted the still celebrated Navicella. He was followed by Gaddi, Stefano, Maso, and Simone Martini (Memmi). But Masaccio (properly Tommaso Guidi, born 1402) first dispelled the darkness of the Middle Ages, and a brighter dawn illuminated the art. The Florentine Republic in the beginning of the 15th century had attained the summit of its splendor. Cosmo de' Medici patronized all the arts and sciences; Brunelleschi then built the dome of the cathedral; Lorenzo Ghiberti cast the famous doors of the baptistery in bronze;

and Donatello was to statuary what Masaccio was to painting. Paolo Uccelli laid the foundation for the study of perspective. Luca Signorelli, who first studied anatomy, and Domenico Ghirlandaio, who combined noble forms and expression with a knowledge of perspective, and abolished the excessive use of gilding, were distinguished in their profession. Leonardo da Vinci (1452–1519), who was a master in all the arts and sciences, infused so much philosophy and feeling into the art that, by his instrumentality, it quickly reached maturity. From him the Florentine school acquired that grave, contemplative, and almost melancholy character to which it originally leaned, and which it afterward united with the boldness and gigantic energy of Michelangelo. The Roman school already enumerated among its founders the miniature painter Oderigi, who died in 1300. He embellished manuscripts with small figures. Guido Palmerucci, Pietro Cavallini, and Gentile da Fabriano were his most distinguished successors. Almost all the painters of this time were accustomed to annex inscriptions to their pictures: the annunciation to the Virgin Mary was their favorite subject. Perugia was the principal seat of the Roman school. As early as the 13th century there was a society of painters there. Pietro Vanucci, called "Perugino" (1446–1524), first introduced more grace and nobler forms into this school, whose character acquired from him something intellectual, noble, simply pious, and natural, which always remained peculiar to the Roman school. Perugino's great scholar Raphael soon surpassed all former masters, and banished their poverty, stiffness, and dryness of style. Taste came into Venice from the East. Andrea Murano and Vittore Carpaccio are among the earliest artists of that city. Giovanni and Gentile Bellino are the most distinguished painters of the earlier Venetian school. The latter labored some time in Constantinople under the reign of Mohammed II. They introduced the glowing colors of the East; their style was simple and pure, without rising to the ideal. Andrea Mantegna (died 1506) was the first to study the ancient models. Padua was the principal seat of the Venetian school. Mantegna afterward transferred it to Mantua, and his style formed the transition to the Lombard school. Schools of painting flourished in Verona, Bassano, and Brescia. Giovanni da Udine (who was so distinguished by his faithful imitation of nature in secondary things that he painted for Raphael the garlands around his pictures in the Farnesina), Pellegrino, and Pordenone were the most able predecessors of the two great masters of the Venetian school, Giorgione and Titian. No capital city served as the central point of the Lombard school. Bologna subsequently became the centre. Imola, Conto, Ferrara, Modena, Reggio, Parma, Mantua, and Milan were afterward considered the seats of this school. Galasio (who lived about 1220), Alighieri, Alghisi, Cosimo Tura, Ercole Grandi, and especially Dosso Dossi (died 1560), were the principal painters of Ferrara. The last, a friend of Ariosto, possesses a remarkable grandeur of style, united with a richness of coloring which may bear comparison with that of Titian. Bramante (died 1514), who was likewise a great architect; Lippo Dalmasi; and especially Francesco Raibolini (died 1517), called "Francesco Francia," were

ITALY

highly distinguished among the Bolognese masters. Here also belongs the charming Innocenzo da Imola.

We now come to the greatest masters of any age, called "Cinquecentisti," from the century in which they flourished. After Leonardo da Vinci, in the Florentine school, had settled the proportions of figures, and the rules of perspective and of light and shade, and his scholars, Luini, Salaino, and Melzo, besides the admirable Baccio della Porta ("Fra Bartolommeo," d. 1517), Andrea del Sarto (d. 1530), the gifted Baldassare Peruzzi and the gay Razzi had made this school distinguished, there arose the most extraordinary of all masters, Michelangelo Buonarotti (1475-1564). His gigantic mind grasped, with equal power, statuary, architecture, and painting. His fire of composition, his knowledge of anatomy, the boldness of his attitudes and foreshortenings, leave him without a rival; but, as a model, he was detrimental to the art, because his imitators necessarily fell into exaggeration and contempt of a simple style. In grandeur his fresco painting, the 'Last Judgment,' in the Sistine chapel at Rome, is imimitable. Beauty was never so much his object as power and sublimity, especially since, in the former, he could never equal Raphael, but in the latter stood alone. Dante was his favorite poet. In his later years the erection of St. Peter's church almost entirely engrossed his thoughts. Rosso de' Rossi, Daniele da Volterra, Salviati, Angelo Bronzino, Alessandro Allori, and many others were his scholars and imitators. If we turn our attention to the Roman school we find at its head the first of artists, Raphael Sanzio da Urbino (1483-1520). His genius showed itself as elevated in his fresco paintings, in the *stanze* and *loggias* of the Vatican (the former of which contain the 'School of Athens,' the 'Par-nassus,' and the 'Conflagration of the Borgo,' while the latter contain Scriptural scenes from the creation through the whole Old Testament), as it appears lovely, spiritual, and original in the frescoes of the Farnesina (representing the life of Psyche). No less superior are his oil paintings, of which we shall only mention his madonnas, celebrated throughout the world, especially the 'Madonna del Sisto' (in the Dresden gallery), the 'Madonna della Sedia' (in Florence), 'Madonna della Pesce' (in Madrid), 'Maria Giardiniere' (in Paris), 'Madonna di Foligno' (in Rome), his 'St. Cecilia' (in Bologna), and his last work, the 'Transfiguration of Christ.' His scholars and successors—the bold Giulio Romano (d. 1546), the more gloomy Gianfrancesco Penni, called "il Fattore" (d. 1528), the lofty Bartolomeo Ramenghi, surnamed "Bagnacavallo," Pierino del Vaga (properly Buonaccorsi), Polidoro da Caravaggio, Gemignani, Benvenuto Tisio da Garofalo, and many others—were skilful masters; but they forsook the path of their great pattern, and degenerated into mannerism. Federico Baroccio (d. 1612) endeavored to counteract this tendency. In spirit he belonged to the Lombard school, as he aimed at, and in part attained, the grace of Correggio. With his scholars Francesco Vanni and the brothers Zuccheri he infused a new life into the Roman school, though the latter produced pleasing rather than great works, and fell into mannerism. Muziano was distinguished in landscape-painting, and Nogari and Facchetti in portrait-painting. At the head of the Vene-

tian school we find the two excellent colorists Giorgione Barbarelli di Castelfranco (d. 1511) and Tiziano Vecelli (d. 1576). The portraits of the former are celebrated for their warmth and truth. The latter was great in all the departments of art, inimitable in his carnation, or painting of flesh tints, excellent as an historical and portrait painter, and the first great landscape-painter. Even in extreme old age his powers were unimpaired. Ariosto and Aretino were friends of the gay, happy Titian. Some of his most famous works are the altar-piece of St. Pietro Martire, his pictures of 'Venus,' his 'Bacchanal,' and his 'Children Playing,' in Madrid, his 'Cristo della Moneta,' etc. He first understood the art of painting with transparent colors. In groups, he selected the form of a bunch of grapes for a model. His successors—Sebastiano del Piombo, Palma Vecchio, Lorenzo Lotto, Paris Bordone, Pordenone—are distinguished especially in coloring. Schiavone, whose *chiaroscuro* and richness of color are truly remarkable; Giacomo da Ponto, called "Bassano," who imitated reality, even in common things, to deception, and who was the head of a whole family of painters; the ardent, inspired Robusti, called "Il Tintoretto" (d. 1594), and the fantastic, splendid Paul Veronese, properly Paolo Cagliari (d. 1588), who painted boldly and brilliantly with a free pencil, but neglected all propriety of costume, and frequently mingled masks in historical paintings, were ornaments of the Venetian school. It likewise degenerated, and its mannerists were worse than those of the other schools, because they did not study the antiques and the ideal. At the head of the Lombard school we find the charming Antonio Allegri da Correggio (d. 1534), whose works are distinguished for harmony of colors as well as for expression and grace. His successors and scholars were Francesco Rondani, Gatti, Lelio Orsi, and especially Francesco Mazzola, called "Il Parmigianino" (d. 1540). This artist possessed much ease, fire, and a peculiar grace, which frequently borders on mannerism. Gaudenzio Ferrari and many others are the ornaments of the Milanese school. In Bologna we find Bagnacavallo (d. 1542), a distinguished artist of this period, whom we have already mentioned as one of Raphael's scholars. Francesco Primaticcio (d. 1570), Niccolò dell' Abbate, Pellegrino Tibaldi, Pasarotti, and Fontana were also celebrated Bolognese artists.

They were followed by the three Carracci, who endeavored to restore a pure style, and, by the combined study of the ancient masters of nature and science, to give a new splendor to the degraded art. Their influence was powerful, and Italian art became divided between the followers of the Carracci, who were called eclectics, and the followers of Michelangelo da Caravaggio, called naturalists. Lodovico Carracci (1555-1619) was, according to some accounts, the uncle, according to others the cousin of the two brothers Agostino (1558-1601) and Annibale (1560-1609). In 1589 all three united in establishing at Bologna an academy for painting, which was called *accademia degli incamminati*, and soon became so famous that all other schools for painting in the city were closed from want of attendance. The scholars of the Carracci are numberless. The most famous endeavored to unite the grace of

ITALY

Correggio with the grandeur of the Roman masters. Cesare Aretusi was distinguished for the most faithful copies of Correggio and Guido Reni (d. 1642), especially for the ideal beauty of his heads, the loveliness of his infant figures and the uncommon facility of his pencil. The Bolognese Francesco Albani (d. 1660) lived in constant rivalry with Guido. He produced many large church paintings, but was most celebrated for the indescribable charm with which he represented, on a smaller scale, lovely subjects from mythology, and especially groups of Cupids. His paintings in the Verospi gallery, and his 'Four Elements,' which he painted for the Borghese family, gained him universal reputation. The background of his landscapes is excellent. All his works breathe serenity, pleasure, and grace. The third great contemporary of those already mentioned, Domenico Zampieri, called "Domenichino" (d. 1641), was at first little esteemed by them, on account of his great modesty and timidity. Thrice were prizes awarded by Lodovico to drawings, the author of which no one could discover. At last Agostino made inquiries, and the young Domenichino timidly confessed that the drawings were his. His industry and perseverance rendered him the favorite of his master. His works evince the most thorough knowledge, and are rich in expression of character, in force, and truth. His 'Communion of St. Jerome,' his 'Martyrdom of St. Agnes,' and his fresco in the Grotta Ferrata, are immortal masterpieces. Giovanni Lanfranco (d. 1647) was especially distinguished for the effect of his light Bartol. Schidone is one of the best colorists of this school. The Bibienas, the Molas, Al. Tierini, Pietro da Cortona, Ciro Ferri, also deserve mention. At the head of the naturalists, who, with a bold and often rash pencil, imitated nature, without selection, stands Michelangelo Merighi, or Amerighi da Caravaggio (d. 1609). The chief of those who in a later age took him as a model was Salvator Rosa (d. 1673), to whose name may be added those of Preti "il Calabrese" and Giuseppe Crespi, called "Spagnuolo." His chief opponent in Rome was D'Arpino, who stood at the head of the idealists, or rather of the mannerists. Caravaggio and his successors, Manfredi, Leonello Spada, Guercino da Cento, etc., often took common nature for a model, which they servilely imitated, thus profaning the genuine dignity of the art, though they cannot be denied strength and genius. About this time, the beginning of the 17th century, the *bambocciate* were introduced. (See LAAR, PETER.) Many artists, especially Michelangelo Crequozzi, surnamed "delle battaglie" and "delle bambocciate," followed this degenerate taste. Andrea Sacchi made great efforts to oppose him. His drawing was correct and grand; Raphael was his model.

Italian art, already in the 17th century very far sunk below the purity of style and the nobility of composition which distinguished it in the time of Raphael, during the 18th century fell into a complete decay. Three or four names of this epoch, those of the Neapolitan Solimena, the Venetians Tiepolo and Canaletto, and the Lucchese Pompeo Battoni, alone deserve to be saved from oblivion. During the first half of the 19th century the artists of Italy still confined themselves to dull imitations of the ancient masters and to academical commonplaces. The

Milanese Andrea Appiani is the only one that need be separately distinguished among the crowd. The other more tolerable painters of this period are Francesco Hayez, Vincenzo Camuccini, Pietro Benvenuti, and Giuseppe Bezzuoli. At the present day an improvement is discernible in the position of Italian art, and serious efforts are being made to rise above the standard of academic conventionality. Among the chief artists are Ussi of Florence, Andrea Gastaldi of Turin, Federigo Faruffini of Sesto, Domenico Morelli, Francesco Castiglione, Camillo Miola, and others belonging to Naples, Pompeo Molmenti of Venice, etc.

In the art of engraving the Italians acquired great eminence. Tommaso Finiguerra, who flourished 1460, was the first celebrated master of this art, which he taught to Baccio Bandini. They were succeeded by Mantegna; but Marco Antonio Raimondi, of Bologna, who lived in 1500, was the first to introduce greater freedom into his engravings. His copies of Raphael have always been highly valued, on account of their correctness. His manner was imitated by Bonasone, Marco da Ravenna, Ghisi, and others. Agostino Carracci, Parmegiano, Carlo Maratti, and Pietro Testa etched some excellent works. Stefano della Bella was distinguished for his small, spirited, and elegant pieces. Among the moderns, Bartolozzi deserves mention in stippled engraving. Cunego, Volpati, and Bettolini are also distinguished; but, above all, Giuseppe Longhi (d. 1831) and the Florentine Raphael Morghen (d. 1833), who carried the art of engraving to a degree of perfection never before anticipated. Among the most celebrated Italian engravers subsequent to these two are Faustino, Pietro Anderloni, Domenico Marchetti, L. Calamatta, Giuseppe Bianchi, Pietro Fontane, Cremonesi, Michele Bisi, Filippo Caporali, Locatelli, and Faruffini.

Sculpture.—Although Italy has possessed some eminent sculptors, this branch of art (apart from some great works of Michelangelo) never attained so high a position in that country as painting. Nothing need be said of the sculptures which decorate the monuments erected during the Romano-Byzantine period of Italian art. For the most part they merely reproduce conventional types, and they are uniformly very roughly executed. To Niccolò da Pisa in the 13th century belongs the honor of having first broken loose from the barbarous manner of the early carvers in stone, and to have taken as models the masterpieces of ancient art. His numerous works (among others the pulpit in the baptistery of Pisa and the tomb of Saint Dominic at Bologna) clearly reveal the new source of inspiration. Niccolò had a worthy successor in his son (according to other accounts brother), Giovanni da Pisa, who in his turn trained up a school of sculptors in the true principles of the art. The most famous of these are the brothers Agnolo and Agostino da Siena and Andrea da Pisa. The influence of Giovanni da Pisa may also be traced in the magnificent works of Masuccio, Pietro, Stefanoni, and others, all of whom were distinguished in architecture as well as in sculpture, for it must not be forgotten that at that time, and even as late as the 15th century, sculpture and even painting were rather regarded as handmaids of architecture, than as separate arts regulated by laws of their own. Hence it was necessary for the archi-

ITALY

tect to possess a thorough knowledge of all the three arts, and thus we find that several masters, such as Giotto, Andrea, Orcagna, Leonardo da Vinci, Michelangelo, and Raphael were at once architects, painters, and sculptors, that others were architects and painters, and still more architects and sculptors. During the 15th century the sculptors of Florence, then the metropolis of the arts, excelled all their rivals, as much as her painters and architects did theirs. At their head stand Lorenzo Ghiberti (d. 1455), and Donatello (d. 1466), both of whom instead of contenting themselves with a mere imitation of the works of antiquity, only looked to them for lessons as to the manner in which nature was to be understood and interpreted, while in other respects they followed an independent path. Among the other great artists of the period were Filippo Brunelleschi, Giacomo della Quercia, and Niccolò d'Arezzo, all of whom besides Donatello were competitors with Ghiberti in the case of the famous bronze doors of the baptistery of the church of San Giovanni at Florence. (See *GIBERTI*.) Giacomo della Quercia afterwards rendered himself celebrated by executing the central door of the cathedral of Bologna. Brunelleschi was so much devoted to architecture that he has left behind him but a small number of sculptures. Luca della Robbia was also eminent among the masters of that time, but his works are chiefly in enameled earthenware, the secret of making which he discovered. The best pupils of Donatello were Desiderio da Settignano (d. 1485), and Andrea Verrochio, a jeweler, sculptor, engraver, painter, and musician, celebrated as the sculptor of one of the most admirable equestrian statues in bronze anywhere to be seen, that of Colleone at Venice, and no less so as the teacher of Leonardo da Vinci and Michelangelo. The other chief sculptors of the 15th century are Matteo Civitali, Benedetto da Rovezzano, and Lorenzo di Pietro (called "Il Vecchietta"), the last also celebrated as a painter and an architect. In Michelangelo the Italian renaissance in statuary reached its highest point. That great artist gave to the human form a character of force and majesty, and in action a fulness and vehemence which he did not always keep within the limits of reality, but which constitute the sublime and truly original aspect of his works. His great misfortune was to be followed by a crowd of imitators, who exaggerated the majesty of his style to a ridiculous extreme. The two most illustrious of his pupils were Montorsoli and Baccio da Montelupo. Sansovino (d. 1570) was able to preserve himself from a servile imitation, and became the founder of a school at Venice, from which proceeded Cattaneo, Pietro da Salo, Jacopo Colonna, and others. Besides these the 16th century numbers among its celebrated masters of the chisel Benvenuto Cellini, more famous as a designer in metal than as a sculptor in marble, Tribolo, Vincenzio Danti, Giovanni Merliano da Nola, called the Michelangelo of Naples, etc. With Bernini in the 17th century statuary underwent a complete decline similar to that which befell the other arts as well as literature during the same period, from which condition it did not rise again till about the end of the 18th and the beginning of the 19th century, when a renewed lustre was shed on the Italian school of sculpture by Antonio Canova (d. 1822), who acquired an immense reputation,

partly justified by the grace of his figures and the delicacy of the execution. After him Lorenzo Bartolini (d. 1850) acquired distinction by the excellence of his works. The chief defect of this artist and of the Italian sculptors of the present age generally is the want of originality of conception and breadth of execution.

Music.—In Italy the imperfect forms of ancient music were first lost in the modern. Here we first find the proper choral song, the foundation of modern church music, which was at first sung in unison, chiefly in melodies derived from the old Graeco-Roman music, and adapted to Christian hymns and psalms. (See *MUSIC*.) It seems to have had its origin when Bishop Ambrosius, in the 4th century, introduced into the Western Church songs and hymns adapted to the four authentic modes of the Greeks, and appointed psalmists or precentors. Gregory the Great, in the 6th century, enlarged the choral song by the plagal modes. From this time singing-schools were multiplied, and much was written upon music. The most important inventions for the improvement of music generally we owe to the 11th century, and particularly to the Benedictine Guido of Arezzo, who, if he did not invent the mode of writing musical notes and the use of the clef, improved and developed them, determined the exact relations of the tones, named six of the tones of the scale, and divided the scale into hexachords. In the 13th century the invention of music in measure was spread in Italy, dependent upon which was that of counterpoint and figured music. Instruments were multiplied and improved in the 14th and 15th centuries. Many popes favored music, particularly vocal, and consecrated it by their briefs; yet the ecclesiastical ordinances restrained the independent development of music. Much instruction was given in singing in the 15th century, and not entirely by monks. Music acquired the rank of a science, and vocal music in counterpoint was developed. In the 16th century we discover distinguished composers and musicians—Palestrina (chapel-master to Pope Julius III.), whose works possess great dignity and scientific modulation; his successor, Felice Anerio; the celebrated contrapuntist and singer, Gregorio Allegri; and the writer upon harmony, Giuseppe Zarlino, chapel-master at Venice. Music was cultivated at Rome and Venice with the greatest zeal. Hence it spread to Naples and Genoa; and all Italy, Schubert says, was soon a loud-sounding concert-hall, to which all Europe resorted to hear genuine music, particularly beautiful singing. About the end of the 16th century we first meet with the opera. The first operatic composer was Jacopo Peri. The taste for this new kind of composition spread so quickly, that composers were soon unable to supply the demands of the people, and from 40 to 50 new operas appeared yearly in Italy. This caused great competition among the Italian musicians. Thus the peculiar character of the Italian music, not to be changed by foreign influence, was developed the more quickly, because this species was cultivated independently, and unrestrained by the church. Already, in the middle of the 17th century, when the music of the theatre was continually advancing, simplicity began to give place to pomp and luxuriance, and the church style to decline. Music (says Schubert) united the profane air of the drama with the fervor of the church style, and

ITALY—ITASCA LAKE

this was the first cause of the decline of the latter. Let us now consider the principal periods of the former. Vocal music must have been first; it was regulated by the discovery and improvement of instruments; thence arose the simple, grand church music of the 15th and 16th centuries; with it various forms of national song were developed. On the stage the higher style of music flourished independently. Here the Italian, without much attention to the poetical part of the performance, which was, as a rule, only the hasty work of a moment, though an exception must be made in favor of the operatic texts of Metastasio, followed his inclination for melody and sweet sounds, which appears even in his language. All the southern nations show a great sensibility, and melody is to them as necessary as harmony to the inhabitants of the north; but to no nation so much as to the Italians, whose beautiful climate and happy organization for song (Italy produces the most beautiful alto and tenor voices—few bass) made melody their chief aim in their music. On the other hand, the simplicity of melody degenerated into effeminacy and luxuriance, from the time when vocal music developed itself independently, and the voice, but little supported by the instrumental music, began to be cultivated like an instrument; when, instead of poetical expression and truth, mere gratification of the ears, not deep emotion, but a momentary excitement, and a rapid change of tones, with the avoidance of all dissonance, were principally desired; when music began to predominate over poetry, which first took place on the stage and thus the musical part of the performance obstructed the improvement of the dramatic and poetic. This taste spread over other countries so much the more easily as Italian music had advanced by rapid strides far before that of the rest of Europe, as appears even from the predominance of Italian terms in the language of music. Among the best composers of the 17th century are Girolamo Frescobaldi, Francesco Foggia, Bapt. Lully, and the celebrated violinist and composer Arcangelo Corelli. To the singers, of whom the most were also composers, belong Antimo Liberati, Matteo Simonelli, both singers in the chapel of the Pope. In the beginning of the 18th century Ant. Caldara was distinguished. He increased the effect of the singing by the addition of instruments, but his style partook much of the theatrical. In the middle of this century Italian music, especially theatrical, flourished, particularly at Naples, Lisbon, and also in Berlin. This has been declared by some the most brilliant period of Italian music. There were some distinguished instrumentalists in Italy, as the organists Scarlatti and Martinelli, the violinist Tartini, Domenico Ferrari, Geminiani, Ant. Lolli, Nardini, and Clementi. Among the composers of the 18th century may be mentioned Traetta, who, through his refinements, injured the simplicity of composition; Galuppi, distinguished by simple and pleasing song, rich invention, and good harmony; Niccolo Jomelli, who gave greater importance to instrumental music; Nic. Porpora, distinguished for his *solfeggios* in church music; Pergolesi, whose music is always delightful from its simple beauty (for example, his *Stabat Mater*); Pater Martini, at Bologna; the sweet Piccini, rival of Gluck; the agreeable Sacchini Sarti. Of a later date are Paesiello, Cimarosa, the ornament of

the *opera buffa*, and Zingarelli (Romeo and Juliet), Nasolini, Paganini, Niccolini, Cherubini, Rossini, Bellini, Donizetti, Verdi, Mascagni, and Perosi.

Italy, Free Church in, a reformed religious sect founded by Alessandro Gavazzi in 1870 (see **GAVAZZI, ALESSANDRO**). In 1874 a confession of faith was formulated, an ecclesiastical constitution framed under a General Assembly; and the title of “Free Church in Italy” assumed. The confession scarcely does more than echo those of the Protestant Churches, and the constitution is based on the government by elders, like that of the Presbyterians, though the several congregations are practically uncentralized, as with the Independents. In 1891 by royal decree, the title “Chiesa Evangelica Italiana” was given to this body. The English sympathizers of Gavazzi bought and presented to the Free Church in Italy the old Church of San Jacopo in Florence, which city is the headquarters of the sect, and the meeting place of the General Assembly, and the present seat of the theological seminary which was originally established at Rome (1875), but transferred in 1891. Gavazzi, a remarkably eloquent man, was appointed professor of dogmatics, apologetics and polemics, as well as of pulpit oratory, a position he held till his death. The schools of the church in Florence are partially supported by the state. According to statistics for 1901 the General Assembly legislates for 30 congregations represented in it, of which there are 14 ordained ministers and 1,831 communicants.

Itasca Lake, farthest source of the Mississippi, in northern Minnesota. (The name is declared by Rev. W. T. Boutwell, a companion of H. R. Schoolcraft in his exploration, to have been barbarously formed in his presence from syllables of Latin *veritas*, truth and *caput*, head, as the “true head” of the Mississippi; but on Schoolcraft’s first map it appears as Itasco, a neighboring stream being named Itasca, and Schoolcraft was a college-bred man hardly capable of such a solecism.) An extremely irregular body of water occupying a glacier-made bowl-shaped depression, surrounded by heights covered with dense forests, interspersed on the slopes with streams, springs, and small lakes often with no apparent outlet. The ground has a substratum of sand and gravel, mingled with large boulders; the surface is spongy and swampy. This basin has been made a national

ITATA CASE—ITO

park of about 7 by 5 miles, containing 19,701.69 acres (30.78 square miles). In the centre, fed by sources so permanent and with a flood plain so small that it has actually risen in dry seasons (though it receded some feet during the 19th century), lies Itasca, a giant among the small ponds around it, but having an area of only 1,130 acres, or $\frac{1}{3}$ square miles. It is composed of a centre running east and west about a mile, whence extend north and south an east and a west arm about $1\frac{1}{2}$ miles long each, and another northward about a mile, the width varying from $\frac{1}{2}$ to $\frac{3}{4}$ of a mile. It has a shore line of 23,000 yards (over 13 miles). Depth, 4 to 50 and 60 feet; average, 20 to 35. The Mississippi flows from its north arm; a strong brook called by Nicollet the "Infant Mississippi" flows into the west arm. See MISSISSIPPI RIVER.

Itata Case, 1891, an important international imbroglio, resulting from the *coup d'état* of Balmaceda (q.v.) and the revolt of the constitutional party in Chile. The latter through an agent had bought a quantity of arms and ammunition in New York, which were shipped to San Francisco and then sent by a schooner to the southern coast, where it was met by the insurgents' vessel, the Itata, and the cargo transferred. The vessel had a few soldiers and a little artillery on board. The attorney-general issued a writ of detention on the ground that she was violating our neutrality laws; and this failing, our cruiser Charleston was sent in pursuit, overhauled and captured her, and placed her on trial before the United States district court at San Diego. The courts discharged her as not having been guilty of such violation. The real interest of the case was political. It was notorious that our government and many of its civil and naval representatives sympathized with Balmaceda against the insurgents, and it was charged with going out of its way in order to cripple the latter; while the other party were ready to make war on the Chilean constitutionalists for defying our authority.

Itch, a contagious disease of the skin (scabies) due to its invasion by the itch-mite (*Sarcoptes scabiei*), now rather rare in civilization. Even the adult mite is so small as to be barely visible, the female being about one sixteenth of an inch long and not quite as wide, while the male is still smaller. It has eight legs, two on each side of the head, to which suckers are attached, and four behind. (See MITE.) The female burrows into the skin and deposits her eggs, about 50 in number, and dies after a period of six weeks. After the eggs hatch out, the young make their way to the surface, and the impregnated females again burrow into the skin, so keeping up the process. The most frequent sites selected by the bugs for their burrows are the web between the fingers, the front of the wrists, the umbilicus, the genitals in men, and the under side of the breasts in women. The first sign of the disease is itching, which forces the patient to scratch, particularly at night, as the warmth of the bed increases the itch. The skin soon becomes inflamed from scratching, and the discomfort is increased. Close examination may show the tiny burrow like a reddened pin-scratch about half an inch long. Many remedies are used with success, but sulphur in the form of an

ointment is the most common. As the bugs cannot be killed while still in the skin, a good plan is to take a hot bath with brisk rubbing, apply the ointment night and morning for three days, continuing to wear the same clothing and sleep in the same bed-clothes; at the end of that time another bath is to be taken, all clothing and bed-clothes changed, and another series of rubbings started. This must be continued as long as fresh burrows are found. Great care must be taken in washing the clothing of an affected person, thorough boiling or baking being necessary to kill the mites. Transmission from one individual to another on close contact is readily effected.

Itch due to varieties of this mite affects all the domestic animals and some wild ones, as the lion, wolf, wombat, etc.; and in Europe, where it occurs more often than in America, epidemics of it sometimes run their course through the dogs, cats, horses, etc., of a town or district, often causing the death of the smaller animals. An application of sulphur ointment is recommended. The itch-mite of fowls is a different species.

Ithaca, Mich., village and county-seat of Gratiot County, on the Ann Arbor railroad, 40 miles northeast of Lansing. It has a courthouse erected at a cost of \$75,000, high school and other public buildings; and manufactures of flour, lumber, wind-mills and agricultural machinery, and several large potteries and iron works. It is the centre of an important agricultural district. Pop. (1890) 1,627; (1900) 2,020.

Ithaca, N. Y., city and county-seat of Tompkins County, on Cayuga Lake, and on the Lackawanna and the Lehigh Valley R.R.'s; 70 miles southeast of Rochester. It derives water power from Fall Creek and has manufactories of autophones, glass, typewriters, drop forgings, calendar clocks, firearms, salt, wall paper, agricultural implements, iron castings, machinery, etc. The city is best known as the seat of Cornell University (q.v.) and the Cascadilla Preparatory School; and also as a popular summer resort. There are two national banks, trolley connection with East Ithaca, large farming trade with Tompkins, Tioga, Cortland, and Seneca counties; and an assessed property valuation exceeding \$7,000,000. In the immediate vicinity are numerous gorges and waterfalls, the most noted of the falls being Triphammer, Ithaca, Taughannock, and Buttermilk. The Taughannock is 215 feet in height and is the highest waterfall east of the Rocky Mountains. There is here the Cornell Free Library containing 21,000 volumes, the Ithaca Conservatory of Music and Renwick Park. Under the charter of 1888, the government is vested in a mayor and city council elected every two years. Ithaca was first settled in 1787 and was called at different periods, "Sodom," "The Flats," and "the city," until 1806, when Simeon Dewitt gave it the name it bears. It was incorporated as a village in 1821. Pop. (1890) 11,097; (1900) 13,136.

Ito, Hirobumi, hē-rō-boō'mē ē'tō, Marquis, Japanese statesman: b. in Choshū province, 1840. When the officer of the deck of the United States S. S. Mississippi, at midnight on 25 April 1854, heard the cry "American, Amer-

MARQUIS HIROBUMI ITO,
Ex-Premier of Japan.

ITURBIDE

ican! he found two Japanese gentlemen who had blistered their hands in rowing a fisherman's boat from the shore to get on board the American warship, hoping to be taken to America. Their clothing was stuffed full of writing paper and materials on which they expected to note down what they saw in foreign countries. One of these was Yoshida Shoin, who had long believed in breaking up the hermit policy of Japan and opening his country to human intercourse. Against his own sympathies, and despite their piteous appeal, Commodore Perry, keeping his word of honor, put the two men ashore. Seized as a prisoner, Yoshida was kept in domiciliary confinement in Choshui for five years, finally suffering decapitation and political martyrdom in Yedo, 31 Jan. 1859. He had for his pupils Ito Hirobumi and Inouye Kaoru. Thus early instructed, Ito determined to see the great world. Getting secretly on board a foreign ship, he reached Shanghai. While his other companions went to Europe by steamer, he and Inouye worked their way before the mast. In London he saw and learned much amid varied experiences, meanwhile making up his mind that Japan must change her entire civilization, cease being Oriental and become modern, or else go the way of India and the conquered Asiatic nations. Hearing that his feudal lord, having erected batteries commanding the straits of Shiminoséki, was about to defy the combined fleets of Great Britain, France, Holland, and the United States, he hastily left for Japan, but at home his efforts did not prevent that bombardment of 5 Sept. 1864 which so enlightened the eyes of the Choshui men, leading them to sink their clan feuds and join with Satsuma, Tosa, Echizen, and others for the restoration of the emperor's power and the unity of all Japan. Active as one of the younger men in the revolution of 1868, he saw the necessity of a uniform coinage. Visiting the United States, he studied American financial history, and on his return the decimal system of money and a mint at Osaka were established. He was one of the first to propose the abolition of feudalism, and in 1872-3 went round the world in the embassy to obtain from the Powers revision of the treaties. As minister of public works he established a college of engineering and secured the building of the railway from Yokohama to Tokyo. After serving as head of the Home Office he visited Europe in 1876 to study the constitutions of the various countries with the idea of forming a written constitution, in fulfilment of the emperor's oath of 1868 to create representative government. He became an intense admirer of the Bismarckian methods and system, and on his return inaugurated a radical plan for altering social customs. As minister president of state, he reconstructed the government, eliminating men of the older traditions and putting in men of modern training. He carried out drastic reforms in economy, besides reconstructing law and codes which, departing widely from those hitherto built on Chinese models, were made in harmony with the jurisprudence of Western countries. In 1888 there was a conservative reaction, and Ito retired to prepare, with three others, the constitution, which was finally promulgated 11 Feb. 1889. Though astonishingly liberal in matters of conscience and personal liberty, it follows the Prussian model in making the ministers responsible

not to the Diet but to the emperor, against which provision the Liberals, eager to follow American and English precedents, have made unceasing protest. This struggle is the key to Japanese politics. Ito wrote a volume of commentaries on the constitution, translated into English by Ito Myoji. Again called to the premiership, he averted a political crisis at home and directed the diplomacy of the Chino-Japanese war of 1894-5. Resigning the premiership, he traveled in Europe, and on his return was again called by the emperor to form a government, and besides working for the Anglo-Japanese alliance, sent 21,000 fully equipped soldiers to join the allies and relieve the legations at Peking. In 1901, after the fall of his "coalition cabinet," he was succeeded by Katsura and went abroad for travel. In the United States for health, he received at Yale University the degree of LL.D. In 1904 he was the emperor's special envoy in Korea to consummate the alliance of the two countries. Enjoying the full confidence of his sovereign, he is, despite his opportunist proclivities, probably the best all-round statesman in Japan's modern history, incarnating, as he does, her past, present, and future.

WILLIAM ELLIOT GRIFFIS,
Author of 'The Mikado's Empire.'

Iturbide, ē-toor-bē'dā, Augustin de, emperor of Mexico: b. Valladolid de Michoacan (now Morelia), Mexico, 27 Sept. 1783; d. Padiña, State of Tamaulipas, 19 July 1824. In 1810 he was lieutenant in the provincial regiment of his native city, but on the breaking out of the troubles in Mexico joined the royalist party, and in this cause displayed such valor and ability that in 1816 he rose to the command of what was called the northern army, which occupied the provinces of Guanaxuato and Valladolid. In 1820 the imprudent acts of the Spanish cortes produced so much exasperation among the clergy and the partisans of absolutism in Mexico, that these persons united to effect the independence of their country, selecting Iturbide as their agent, and appointing him commander of the army in the south. He quickly bore down all opposition, and became so popular that he had himself proclaimed Emperor of Mexico, in July 1822, under the name of Augustin I. The Congress declared the throne hereditary in his family, and voted him a yearly allowance of \$1,500,000. His troubled reign came to an end in less than a year, by his abdication in March 1823. Congress granted him on his abdication a yearly pension of \$25,000 on condition of his leaving the country, making sufficient provision for his family in case of his death. He resided in Leghorn for about a year, when he was induced to make an attempt to recover his lost crown. He landed with but a single attendant at Soto la Marina, and was arrested and shot. His family settled in Philadelphia, where his widow died in 1861. Several of his sons subsequently held positions under the Mexican government, the eldest, Prince Angel, dying in the City of Mexico in 1872, the youngest, Prince Augustin, dying in Paris in 1873. Prince Angel's son, Augustin, b. 1864, was adopted by the Emperor Maximilian as his heir, Maximilian himself being childless. The collapse of the second empire, however, destroyed his chances of a throne.

IUKA — IVORY

Iuka, Miss., a small village on the Memphis & Charleston railroad, in the northern part of the State, about 115 miles east of Memphis, was the scene of a severe engagement during the Civil War. Early in September, 1862, it was occupied by a small Union regiment as an outpost. On the morning of 13 September Gen. Sterling Price, moving north from Tupelo with a force of 14,000 men, to prevent Grant from sending reinforcements to Gen. Buell in Kentucky, drove the Union regiment from the village and occupied it, and on the 19th was about moving to Rienzi on the Mobile & Ohio Railroad to form a junction with Earl Van Dorn's army preparatory to an attack upon Corinth. Gen. Grant had been closely watching the movements of Price and Van Dorn, and when he heard that Price had occupied Iuka he determined to attack and cut him off before he could effect a junction with Van Dorn. Gen. Rosecrans, who was near Corinth with 9,000 men, was ordered to move south to Rienzi and Jacinto, then eastward, and, marching on the roads from Jacinto and Fulton, to attack Iuka from the south. Gen. Ord, with 6,500 men, was to move along the Memphis & Charleston Railroad to Burnsville, thence by roads north of the railroad, and to attack on the north and west of Iuka. Grant accompanied Ord, who reached Burnsville on the 18th, and encamped within six miles of Iuka, which he proposed to attack early in the morning; but Grant, hearing that Rosecrans had been delayed in his movements and would not probably be up in time to attack next day, instructed Ord not to move to the attack until the sound of Rosecrans' guns was heard south of Iuka. Rosecrans, with the two divisions of Hamilton and Stanley, moved from Jacinto at 5 o'clock in the morning of the 19th and, after a march of 18 miles, at 4 P.M. his advance division (Hamilton's), about two miles south of Iuka, encountered Little's division of Price's command, Maury's division remaining in the north of Iuka, to confront Ord. Little had about 4,000 men, with which he attacked Hamilton vigorously before the latter could complete his lines. After a very severe fight, Hamilton was driven back some 600 yards, abandoning nine guns; but, receiving three regiments of Stanley's division as a reinforcement, he rallied and regained part of his lost ground, when darkness ended the fighting. Gen. Price reports: "The fight began, and was waged with a severity I have never seen surpassed." Price prepared to renew the battle in the morning; but, convinced by his subordinates of the critical position he was in with Rosecrans in his front and Ord in rear, retreated southward by the Fulton road, which Rosecrans had failed to close as was intended. Ord did not hear the sounds of battle on the 19th, but, advancing on the morning of the 20th, found that Price had escaped. Price retreated southward and reached Baldwyn 23 September. Rosecrans and Ord returned to Corinth. Rosecrans reported a loss of 144 killed, 598 wounded, and 40 missing. Price reported a loss of 86 killed and 408 wounded; Union estimates placing it much higher. Consult: 'Official Records,' Vol. XVII.; Greene, 'The Mississippi'; the Century Company's 'Battles and Leaders of the Civil War,' Vol. II.

E. A. CARMAN.

Ivan, ē-vän', the name of several rulers distinguished in Russian history. The most celebrated are the Grand Dukes Ivan III. and Ivan IV., who laid the foundations of the Russian Empire, the latter (b. 1529; d. 1584) being commonly known as Ivan the Terrible. (See RUSSIA.) Ivan VI. was son of the Grand-princess Anna and of Antony Ulrich, duke of Brunswick-Wolfenbuttel. The Empress Anna, 1740, declared him her successor, and her favorite Biron was to be his guardian and regent. Biron caused the oath of allegiance to be taken to the prince, and when he was banished the parents of the child assumed the reins of government until the daughter of Peter I., Elizabeth, ascended the throne. The young Ivan was taken from his cradle by soldiers, and shared the fate of his banished and imprisoned parents.

Ivanhoe, the title of one of Sir Walter Scott's most famous novels, written and published in 1819. The manuscript is now at Abbotsford. Immediately after its appearance, 'Ivanhoe' became a favorite, and now ranks among the most brilliant and stirring of romantic tales. The scene of the tale is England in the reign of Richard I.

Ives, ivz, Brayton, American financier: b. Farmington, Conn., 1840. He was graduated from Yale in 1861, served in the Union army in the Civil War, attaining the rank of colonel, 5th Connecticut infantry, and brevet brigadier-general, in 1867-89 was a broker of New York, and in 1878-9 president of the New York Stock Exchange. At one time president of the Northern Pacific railway, he later was chosen to the presidency of the Metropolitan Trust Company of New York.

Ives, Frederic Eugene, American inventor: b. Litchfield, Conn., 17 Feb. 1856. He received a public school education; was director of the photographic laboratory at Cornell University in 1874-8, and has lectured before scientific societies in this country and in England. Among his inventions are the process of half-tone photo-engraving (1878); and the three-color printing process in the typographic press. He has published: 'Isochromatic Photography with Chlorophyll' (1866); 'A New Principle in Heliochromy' (1889); etc.

Ivory, properly the substance of which the tusks of the elephant consist, though the similar substance constituting the tusks of the hippopotamus and the horn of the narwhal is also so called. There is also a wholly different substance known as vegetable ivory (q.v.). Ivory is prized for its beautiful color, the fineness of its grain, and the high polish it is capable of receiving. That of the African elephant is most esteemed by the manufacturer for its density and whiteness. It is used as a material for knife-handles, pianoforte keys, combs, the backs of brushes, billiard balls, chess-men, carved figures, and ornamental articles of various kinds. Thin plates of ivory are used as panels for miniature paintings, and etchings are sometimes executed on such plates. The ivory of the hippopotamus is preferred by the dentist. The shavings and sawdust of ivory, by burning in a crucible, are converted into a black powder, from which is prepared a pigment known as ivory black. Ivory may be stained or dyed. The use of ivory was well known in very early

IVORY-BILL — IXION

ages. The ancients were acquainted with the art of sculpturing in ivory, of dyeing and inlaying it, and they often employed it in statuary. Some of the most famous Grecian statues were chryselephantine, that is, were overlaid with plates of gold and ivory in conjunction. To provide the world's supply of ivory it is estimated that 9,000 to 12,000 elephants are killed annually. The medium weight of a tusk is about 60 pounds, but some are found weighing as much as 170 pounds.

Ivory-bill, the great black-and-white, scarlet-crested woodpecker (*Campetherus principalis*), formerly numerous and greatly admired throughout the Southern States, but now surviving only in a few of the most secluded cypress swamps of the Gulf coast. Its extermination was begun by the Indians, who valued highly its splendid head-feathers as an ornament for warriors; and completed by sportsmen and plume-hunters. The books of Wilson, Audubon and early writers on American animals give many interesting facts as to its habits.

Ivory Palm, a South American palm-tree yielding corozo-nuts,—large white seeds called "vegetable ivory" (q.v.).

Ivory, Vegetable. See VEGETABLE IVORY.

Ivy, a popular name for various climbing, creeping, and drooping herbs and shrubs, the most widely known of which are the following: Common or English ivy (*Hedera helix*) is a tall climbing evergreen shrub of the order *Araliaceæ*, widely planted in Europe (where, as in Northern Africa and Eastern Asia, it is native), and in the warmer parts of the United States, its ornamental, abundant foliage being highly valued for covering walls, rocks, and trellises. Its small and inconspicuous greenish, perfect flowers appear late in the autumn and the small black fruits (three to five seeded berries) ripen the succeeding year. The fruits, which are devoured by birds, are bitter and pungent, and were formerly in medicinal repute. The gummy juice obtained from the stem, as also the fruit, contains the bitter principle hedelin and the hederic acid characteristic of the plant. It has been used in making varnish. Contrary to popular opinion, ivy is not parasitic upon such trees as support it. It merely clings to them by its numerous hold-fast roots produced along the entire length of its stems. Such trees as it injures are killed by constriction. The other popular notion that it makes the walls and houses upon which it climbs damp and unhealthy is also erroneous; in reality it dries them, the roots abstracting such water as reaches the wall through the dense foliage; yet exceptional cases of damage occur. It has numerous horticultural varieties which differ mainly in the form, color and markings of the leaves. These succeed best in rather moist, rich soils and shady positions and are not usually found to be hardy much farther north than New York unless well protected from the winter sun, as upon the north side of buildings, etc. As a cool greenhouse and a house plant it is very popular. Ivy leaves and ivy berries were formerly administered for various medicinal purposes, but they have been long out of use. The leaf and habit of the common ivy are so characteristic that reference is often made to them in the

specific names of other plants, "ivy-leaved" being common as a designation. The plant takes a prominent place in mythology and folk-lore.

Japanese or Boston ivy (*Ampelopsis tricuspidata*) and its near relative Virginia creeper (*A. quinquefolia*) of the order *Vitaceæ*, are probably the next best known species to which this name is applied. The former is the more graceful, and is gradually gaining in general favor over the latter, which demands more attention to keep it looking presentable. Both climb by means of tendrils, but the Boston ivy clings better to walls. It has three-lobed leaves; its rival, five-lobed. Both have brilliant autumnal colors in the north, where the Virginia creeper is the more hardy.

Among the herbaceous ivies Kenilworth ivy (*Linaria cymbalaria*), German ivy (*Senecio mikanooides*) and ground ivy (*Nepeta glechoma*) are best known in America. They are all popular greenhouse plants and are frequently planted in hanging-baskets because of their graceful habits. Poison-ivy or poison-oak is a climbing sumach whose leaflets somewhat resemble those of Virginia creeper, but are in threes instead of fives (see POISON-IVY).

Iwakura, Tomomi, Japanese reformer and statesman: b. in Kioto in 1825 of illustrious ancestry, one of the Kuge or court nobility, chamberlain of the imperial household, and at first in favor of the expulsion of foreigners. He never saw a foreigner until he was 43 years old. Becoming a Progressive, he was banished into exile and shaved his head, but his real aim was to restore the lustre of the imperial throne by the overthrow of the Yedo Shogunate. Entering into communication with the leaders of the confederation of southern daimios, he became the link between court nobility and the progressive samurai or gentry, and took a prominent part in the Restoration of 1868. He was one of the first to send his three sons to be educated under Verbeck and to America. He received high office and salary, and in 1870, as envoy of the mikado to the recalcitrant Satsuma leaders, led in the movement to abolish feudalism, and was prominent in securing the formation of a new national army. As minister of foreign affairs and junior premier, he was visited by his sovereign. He went to Europe and America as head of the great embassy of 1872. He admired greatly the government at Washington. He left a powerful impress on the nation and the sovereign, and received the highest honors due to a subject. Escaping all attempts at assassination, he died quietly in his bed 20 July 1883. Of his children, a son, Prince Iwakura Tomosada, of the House of Peers, is special attendant upon the emperor, and the other, a daughter, is at the head of the Red Cross work in Japan. .

WILLIAM ELLIOT GRIFFIS,
Author of 'The Mikado's Empire.'

Ixion, iks-i'ón, in Greek mythology, king of the Lapithæ in Thessaly, son of Phlegyas. He married Dia, daughter of Deioneus. He became enamored of Hera, and attempted to seduce her. Zeus made a cloud in the shape of Hera, and carried it to the place where Ixion had appointed to meet her. Ixion was caught in the snare, and from his embrace with the cloud were born the Centaurs. (See CENTAURS.) Zeus banished him from heaven:

IYAR — IZARD

struck him with his thunder, and ordered Hermes to tie him to a winged or fiery wheel in Hades.

Iyar, the eighth month of the Jewish year, corresponding, at the earliest, with April; but it may be as late as May; it has only 29 days.

Iz'ard, George, American general: b. Richmond, Surrey, England, 1777; d. Little Rock, Ark., 22 Nov. 1828. He was a son of Ralph Izard (q.v.). He was graduated from the College of Pennsylvania in 1792, and after a tour in Europe was appointed in 1794 a lieutenant in the regiment of artillerists and engineers in the United States army. Upon the breaking out of the War of 1812 with Great Britain he served as colonel of the 2d artillery, and was successively promoted to be brigadier-general and major-general. At one period of the war he held chief command of the northwest frontier. In 1825 he became governor of Arkansas Territory, in which office he died.

Izard, Ralph, American statesman: b. near Charleston, S. C., 1742; d. South Bay, near Charleston, 30 May 1804. He was educated at Christ's College, Cambridge, England, and, in-

heriting an ample fortune, established himself in 1771 with his family in London, whence the troubled condition of American politics induced him in 1774 to retire to the continent. He subsequently endeavored to impress upon the British ministry the ill-advised nature of the course they were pursuing, but without effect. In 1780 he returned to the United States, and found occasion to serve the country in various ways, having been instrumental in procuring the appointment of General Greene to the command of the southern army, and having once pledged his whole estate as security for funds needed in the purchase of ships of war in Europe. In 1781 he entered the Continental Congress, of which he remained a member until the peace; and upon the adoption of the Federal constitution he was elected a United States senator from South Carolina. As a legislator he was able and eloquent and in the senate possessed the confidence of all parties. The 'Correspondence of Ralph Izard from 1774 to 1804, with a Short Memoir,' was published by his daughter (1844).

Izard, the chamois (q.v.); so called in the Pyrenees.

J

J the tenth letter of the English alphabet, was unknown to the ancient Latins and Greeks as an alphabetic character and representative of a vocal sound.

Till the 16th century the Latin and other alphabets of western Europe had only the letter i to represent both the vowel sound i and the consonant sound now represented by j: at least in fonts of type of that century, and till the end of that century or later, the character i served to represent both the vowel and the consonant, though a distinction was made between them in manuscripts of the previous century by continuing the stroke of the i a little below the line when it stood for the consonant. This letter j from the first represented in English the sound of dzh, in French that of zh; in German and other languages its value is that of the consonant y; for example, Julius, pronounced yulius, jacio, pronounced yacio.

For speakers of the modern European languages the j in Latin has usually the same value as in their native tongues. But though for Spaniards j in Latin is equal to y, in their own speech j is a strong guttural aspirate that might be represented in English by kh. The sound of j in English is always represented in Italian by g: the French and English journal is in Italian *giornale*, the Latin *judex*, English judge is in *italian giudice*.

The sound of dzh is represented in English not only by its proper letter j, but also by g and by dg: jest, gem, edge.

Jabiru, jab'i-roo, a large species of stork (*Mycteria americana*), somewhat resembling the adjutant, found nearly throughout South America and northward into Mexico and Texas. It is about five feet high, with stilt-like legs, and massive, slightly upcurved beak; the plumage is white and the naked head and neck black. In habits it resembles the other storks (q.v.). Several related Oriental species have received the same name.

Jaborandi, a Brazilian shrub (*Pilocarpus pennatifolius*) of the order *Rutaceæ*, which yields a volatile oil from which is derived a principle (pilocarpin) in the form of an amorphous white powder having properties similar to atropine. It is the basis of the drug jaborandi, which is diaphoretic and sialagogic in its effects. Other "jaborandis" are obtained from species of *Serronia*, *Aubletia* and *Piper*.

Jac'amars, a group of small, gaudy, South American birds of the family *Galbulidae*, and related to the puff-birds and woodpeckers. Their plumage is highly colored, reds and bronzy

greens and blues predominating. They live mostly along the outskirts of forests, and feed upon large insects caught in flight. White eggs are laid in holes in earthen banks; and a whistling song is given during the breeding season.

Jaganas, zhä-sä'nä or jä-kä'na, a group of birds (*Parridae*) related to the rails, and remarkable for the extraordinary length of the toes, which are further extended, especially the hallux, by long, slender claws. There are four genera and about a dozen species, most of which inhabit the Old World—Africa, India, and Australia. The genus *Parra* is American, and one Mexican species (*Parra spinosa*) enters Texas. The beak is plover-like and the bend of the wing bears a stout and acute horny spur; the plumage is of a rich purplish brown with the wings green and black. The great spread of the toes enables these birds to walk with ease on the floating leaves of water lilies and similar plants, otherwise their habits are much like those of rails (q.v.).

Jacaran'da, a genus of tropical American trees of the *Bignonia* (q.v.) family. One (*B. brasiliiana*) yields the wood called jacaranda wood, or blue ebony, which is very hard and capable of receiving a fine polish. The name is carelessly applied to several other South American woods used in cabinet-work.

Jacaré, zhä-kä-ra' or jäk'a-rë, a South American name for an alligator of the genus *Caiman*, of which the large black species (*C. niger*) reaches a length of 20 feet and is called on the upper Amazon jacaré-nassu, while the jacaré-tinga (*C. trigonatus*) is only six feet long, and has a slender muzzle and black-banded tail. See CAYMAN.

Jack, a pike; in the United States, the common eastern pickerel (q.v.) is most usually meant. The wall-eyed pike (q.v.) is called "jack salmon" in some parts of the West. Several marine fishes are known as jack fish, amber jacks, etc., especially among the lively sea-bass, groupers, amber-fish and the like. The term, as in other cases, implies a quality in the animal exciting friendly interest and admiration.

Jack, or **Jack-tree** (native name *Jaca*), a tree (*Artocarpus integrifolia*), related to the bread-fruit (q.v.), a native of India and southeastern Asia. The fruit grows to a larger size than the bread-fruit of the Southern Pacific islands, often weighing more than 30 pounds, and containing from 200 to 300 seeds, each of them four times as large as an almond. The seeds or nuts are eaten after being roasted or boiled, and the sweet fleshy pulp of the fruit is also eaten. When the tree is young the fruit

JACK AND THE BEANSTALK — JACKDAW

grows from the twigs; in middle age it grows from the trunk; and when the tree gets old, from the roots. It forms a great part of the food of the natives in some portions of India, Ceylon, etc. The yellowish timber is used for almost every purpose, being strong and ornamental, and yields a yellow dye.

Jack and the Beanstalk, an English nursery tale relating to the heroism of a boy. Its analogue occurs in many national folk-lore legends. It is supposed to represent in a figure the restoration to the earth of those fertilizing and elemental activities, which are necessary to human life. The harp is the wind, which drives the ships and turns the mills to grind the wheat. The bags of treasure are the rain-drops that scatter wealth and plenty. The red hen is the sun that brings life to birth by its fostering heat.

Jack and Jill, the first words of an old nursery rhyme, of considerable folk-lore interest. Jill is a corruption of the French Julianne, once common in England under the form Gillian. It also appears in the legend of St. Kilian, where Geilana vindictively causes the good bishop's death. This incident of Jack and Jill is probably based on one of the moon myths of Scandinavia. The Norse peasant sees in the spots on the moon the two children rescued by the moon from their father, who had forced them to draw water all the day.

Jack the Giant Killer, the hero of an English nursery story, which reflects triumph of skill over strength and bulk such as makes the point of the story in David and Goliath, Ulysses and Polyphemus, etc. The English form is based upon the legend that St. Michael's Mount, in Cornwall, was once the fortress or castle of a giant, who was dislodged by the valor of an English knight. In adapting the story so as to claim the sympathies of children the knight is made to take the shape of a child.

Jack Horner, the first words of an old nursery rhyme. The rhyme is said to be based on a historic fact. Horner was the messenger whom the abbot of Glastonbury sent to Henry VIII. with the deeds of certain manors involved in the dissolution of monasteries. Horner obsequiously handed the parcel to the royal spoliator, but first of all managed to abstract the deeds of the manor of Wells, a "plum" indeed, and the abbot was afterward punished on the charge that he had withheld them.

Jack-in-the-Pulpit, or **Indian Turnip**, a perennial herb (*Anisoma triphyllum*) of the arum family (see *Araceæ*). Its name is derived from its spadix, which is upright, with the spathe surrounding and arching over it, suggesting a preacher in an old-fashioned pulpit with a sounding-board. It is common in the United States, east of the great plains, in damp, shady woods and in moist garden soil; and when the spathe falls away in early summer, the red berries are prominently shown in the form of a dense ovoid head. Its acrid tuber or corm is valued for its medicinal properties, and may be made edible by boiling.

Jack-snipe, a gunner's term for a shore-bird, also called grass or meadow snipe, which is in reality a sandpiper, named in books the pectoral sandpiper (*Tringa maculata*). The per-

version of names is due to its somewhat game-like habits of lying to a dog and flushing correctly from the grass, like a true snipe which render it an attractive object of pursuit; beside which, in the fall it becomes very fat, and it is then excellent eating. Unlike most sandpipers, it does not flock, at least to any extent, being oftenest found scattered singly or in pairs. In the United States it is chiefly, if not wholly, a bird of passage, breeding in Canada and wintering in the tropics. It is nine inches long, clay-colored, striped with blackish above; breast ashy and sharply streaked; belly white. Consult authorities mentioned under shore-birds.

The English "jack-snipe" is a true snipe (*Gallinago gallinula*) of very small size, and therefore also known as "half-snipe."

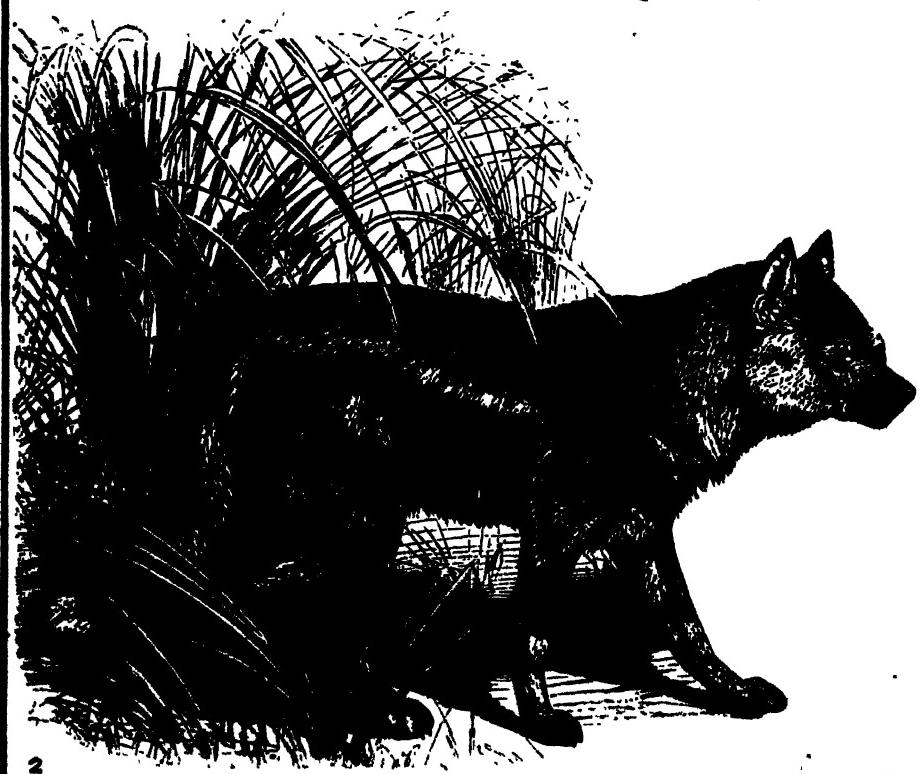

Jack' al, a small active wild dog or wolf of the warmer regions of the Old World, found in southeast Europe, Africa, Syria and southern Asia. The common jackal averages about 2 or 2½ feet in length, and about 14 inches in height, with a bushy tail about 8 inches long. The eyes are small, and the pupil is round. The general color of the body is a dirty yellow or brown, lighter on the throat and belly. Jackals inhabit holes and burrows whence they come forth in the evening to hunt in packs. Their cry consists of a series of prolonged howls, followed by shorter yelps, much like that of the American coyote. The jackal subsists largely upon carrion, often that left after the repast of the fiercer and larger carnivora: but it also kills prey for itself, a pack hunting down antelopes, deer, or other animals, besides getting much small fare, as mice, lizards, insects and the like. They also eat certain kinds of vegetable food, and sometimes they do considerable damage to sugar and other plantations. The jackal is susceptible of being tamed, but its odor makes it by no means a desirable domestic animal. It is believed to be exceedingly cunning, and in many Eastern tales, especially among the people of India, plays exactly the same part as the fox does in those of Europe. It is probable that jackals have contributed frequently to the commingled stock represented in our domestic dogs, some of which betray very jackal-like points. They inter-breed with domestic races.

The common jackal (*Canis aureus*) is the most widely distributed species: but another species, found mostly in southern Africa, is the blackbacked jackal (*C. mesomelas*). This latter form has the back and end of the tail black, the other parts mostly red or yellowish-red. A third species of jackal found in South Africa is the canduc (*C. adustus*), marked by a light stripe on the sides. Consult: Mivart, 'Dogs, Jackals, Wolves and Foxes' (London 1890).

Jackass Kingfisher, or **Laughing Jackass**, the name of a large inland kingfisher (*Dacelo-gigas*) of Australia, given by the colonists in allusion to its loud, hoarse cry. It is about 17 inches long, brown in general color, does not frequent water or catch fish, but lives on insects, small reptiles, etc., and lays its eggs in a hole in a tree.

Jack'daw, a small, black European crow (*Corvus monedula*), with black legs and feet

JACKALS.

2

1. Common Jackal.

2. Side-striped Jackal.

JACKMAN — JACKSON

and grayish neck. They inhabit towers, spires, and like elevated situations, and even in towns and populous cities are present and breed freely. The nests and eggs are like those of other crows (q.v.) which they resemble in general habits. Jackdaws are easily tamed, learn to pronounce many human words, and are most amusing pets, but are mischievous and thieving, like magpies.

Jack'man, Wilbur Samuel, American educator: b. Mechanicstown, Ohio, 12 Jan. 1855. He studied at Allegheny College (Meadville, Pa., 1880-2), was graduated from Harvard in 1884, and later became dean of the school of education in the University of Chicago, and head of the natural science department of the school. In 1899-1900 he visited Holland, France, and Germany for the study of educational methods. In addition to many articles on pedagogical topics, he has published: 'Nature Study for the Common Schools' (1891); 'Number Work in Nature Study' (1893); 'Field Work in Nature Study' (1894); 'Nature Study Record' (1895); 'Nature Study and Related Subjects' (1898); and 'Nature Study for the Grammar Grades' (1898).

Jackrabbit. See HARES.

Jack'son, Abraham Valentine William, American Indo-Iranian scholar: b. New York 9 Feb. 1862. Graduated from Columbia in 1883, he was Fellow in letters there (1883-6), instructor in Anglo-Saxon and the Iranian languages (1887-90), and, after study at Halle (1887-9), adjunct professor of English language and literature (1891-5). In 1895 he was appointed professor of Indo-Iranian languages at Columbia. By way of recognition of the instruction given by him in their ancient books, the Parsees made to the Columbia library the gift of an important manuscript collection of Zoroastrian works. He appeared also as a public lecturer, became one of the directors of the American Oriental Society, and in addition to numerous contributions to the 'Journal' of that society and other learned periodicals, wrote: 'A Hymn of Zoroaster, Yasna XXXI.' (1888); 'An Avestan Grammar' (1892); 'An Avestan Reader' (1893); 'Zoroaster, the Prophet of Ancient Iran' (1899).

Jackson, Abraham Willard, American Unitarian clergyman and author: b. Portland, Maine, 7 April 1843. He was graduated from Colby University (Waterville, Maine), entered the Union army as private in the 8th Maine volunteers, became captain in the 33d United States colored troops, in 1872 became pastor of the Unitarian Church at Peterboro, N. H., and subsequently of that at Santa Barbara, Cal. In 1894-5 he was acting professor of philosophy in the Meadville Theological School. Among his writings are: 'The Immanent God' (1880); 'James Martineau: a Biography and Study' (1900); 'Deafness and Cheerfulness' (1901).

Jackson, Andrew, seventh President of the United States: b. Waxhaw settlement, N. C., 15 March 1767; d. near Nashville, Tenn., 8 June 1845. He was of north of Ireland ancestry, his father emigrating to America from Carrick Fergus in 1765. As a boy Jackson was reckless, impetuous, quarrelsome, and passionate in temper; thoroughly disinclined to learning of

any sort, his favorite pursuits were racing, gambling, and cock-fighting, but he was possessed of invincible determination, dauntless courage, and excelled in marksmanship and riding, qualities which later served him well. After some desultory law study in Salisbury, S. C., he became in 1788 public prosecutor of the Western District of North Carolina (that is Tennessee). In 1791 he married Rachel Robards, both supposing the latter's husband, Lewis Robards, had secured a divorce by act of the Virginia legislature. This proving not to be the case, they were remarried in 1794. This incident was frequently used against Jackson in his political campaigns, but his only fault was in not ascertaining more surely the exact terms of the Virginia act. A member of the Knoxville convention which drafted a constitution for Tennessee, Jackson was elected the first Federal representative of that State after its admission to the Union, June 1796. Appointed U. S. Senator in 1797 he resigned in April 1798 to become judge of the Tennessee supreme court, holding the position until 1804 when he retired to devote himself to settling his private affairs which had become heavily involved in debt. Between 1806-11 he led the life of a planter, storekeeper and private citizen without noticeable incident. Upon the outbreak of the war of 1812 Jackson, then major-general of Tennessee militia, promptly offered his services with those of 2,500 volunteers. New Orleans being considered a probable objective of the enemy, Jackson was sent there, 7 Jan. 1813, but was soon ordered to dismiss his troops and return. Thoroughly enraged, he hired transportation on his own authority and marched his men home in a body, refusing to disband them without pay or rations, five hundred miles from home. In June the government reimbursed him for the expenses incurred. It was during this expedition his soldiers bestowed on him the affectionate name of "Old Hickory." On 30 Aug. 1813, the massacre of the garrison and refugees at Fort Mims, at the junction of the Alabama and Tombigbee rivers occurred. Tennessee at once voted men and money to aid in suppressing the Indian outbreak. Jackson, though suffering from a wound received in a tavern brawl, took the field, and in a whirlwind campaign completely crushed the Creeks at Horseshoe Bend, Alabama, 27 March 1814. On 14 March 1814, he ordered John Wood to be shot for insubordination and assaulting an officer, the first of the military severities afterward brought up against Jackson during his Presidential campaigns. On 31 May 1814 he was appointed major-general of the United States army, commanding the department of the South. In November, without orders from Washington he marched against the English Pensacola, easily stormed the town and compelled their withdrawal. Proceeding to New Orleans he began energetic preparations for defense, amid the greatest difficulties and who lacking in proper means and materials. On 28 Dec. 1814 and 1 Jan. 1815 he gained minor successes against the British. On 8 Jan. 1815 General Pakenham with 10,000 veteran troops delivered a grand assault upon Jackson's works. The result was a complete defeat and rout of the British, they losing over 2,600 in killed, wounded and prisoners, while Jackson's loss was seven killed and six wounded. The treaty of peace

JACKSON

had been signed at Ghent 24 Dec. 1814, but Jackson did not learn of it until 6 March 1815. Accordingly he relaxed none of his vigilance, but kept the city under martial law, during which his characteristic highhandedness brought him into sharp conflict with the civil authorities. For disciplinary reasons six soldiers were court-martialed and shot on 21 February. But Jackson's brilliant and unexpected victory, the one great land success of the War of 1812, set the country afire with enthusiasm. From an obscure planter he immediately became the most popular man in the country. Resolutions of thanks and praise poured in on him from State legislatures; Congress voted him its thanks and a gold medal, and his exploit was the political salvation of the tottering administration. During the Seminole war Jackson was ordered to take command in Georgia, December 1817. Within five months he broke the Indian power completely, established peace on the border, and practically conquered Florida. His hasty measures, undertaken on inadequate facts and information, caused considerable anxiety and discussion in the government. His invasion of Florida and capture of St. Marks, a Spanish possession, and his summary execution of Arbuthnot and Ambrister, two British subjects, seemed likely to raise delicate diplomatic situations. Upon the acquisition of Florida Jackson was appointed its first territorial governor, April 1821, with almost the powers of a Spanish captain-general, but, disgusted with the office, he resigned in October. Parton describes his conduct while governor as "arrogant and disgraceful." In 1823 he declined the mission to Mexico, and was an unsuccessful candidate for the presidency in 1824. But in 1828 backed by the powerful influence of Van Buren in New York and his own popularity in Pennsylvania, which thus assured him the support of the two largest eastern states, Jackson was triumphantly elected President, the first representative of the new West and the masses. In 1832 he was re-elected by a larger electoral vote than in 1828. His first cabinet was composed of almost unknown men. For advice and counsel he relied chiefly on a group of personal friends and intimates, among them being Wm. B. Lewis, Amos Kendall, a representative of all that was vicious in American political methods, Duff Green and Isaac Hill, partisan editors, and later Francis P. Blair, who edited the '*Globe*' in Jackson's interest. This group formed what came to be known as the "Kitchen Cabinet." In 1830 Jackson endeavored without success to enforce the social recognition of the wife of his secretary of war, John H. Eaton. The chief features of his administrations may be briefly summarized. That to him is due the shackling of the spoils system upon the country may be seen from the fact that between 1789 and 4 March, 1829, there were only 74 removals from office, while during Jackson's first official year there were some 2,000. He vigorously opposed the second bank of the United States, and vetoed the bill renewing its charter, 1832. He put a prompt end to South Carolina's nullification proceedings by his proclamation of 10 December 1832, declaring nullification contrary to the Constitution and incompatible with the existence of the Union, and his active preparations to execute the laws, by force

if needful. In 1834, as a result of his action in ordering the secretary of the treasury to cease making deposits of government funds in the Bank of the United States, the Senate censured him for usurpation of powers not conferred by the laws or Constitution. His Specie Circular of 11 July 1836 directing that only gold and silver be taken at the land offices in payment for public lands was an important factor in the causes leading to the financial crash of 1837. His foreign policy was firm and successful. The disputes with Great Britain over the northeast boundary and the trade between the United States and British colonies, and with France over the indemnity for spoliations committed on American commerce early in the century, were dealt with shrewdly and with success.

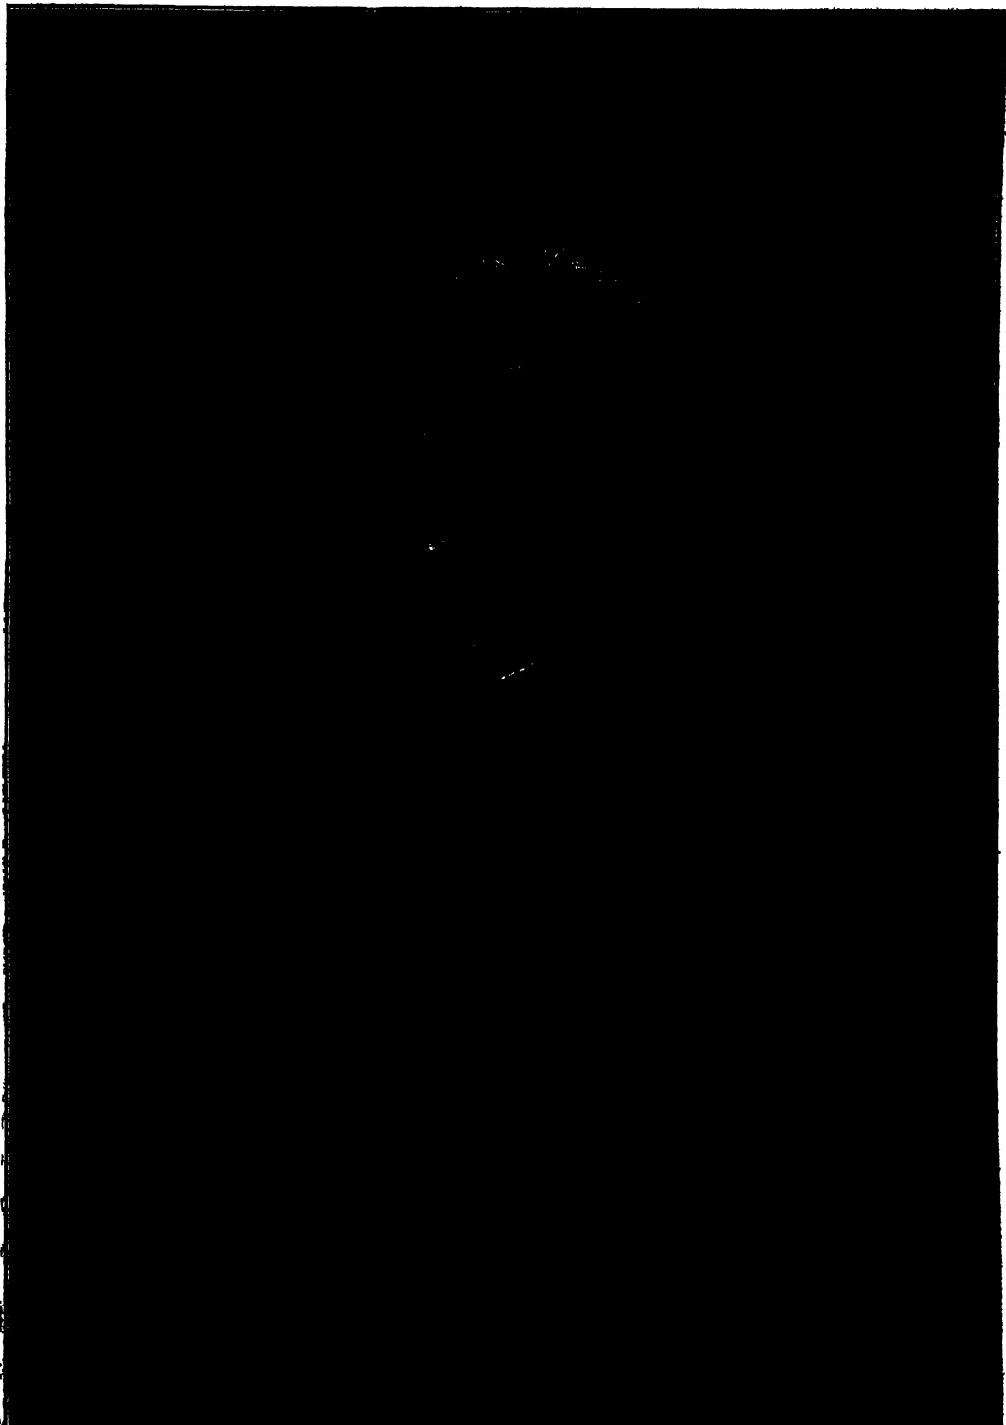

Opinions will always be divided regarding Jackson's character. For thirty years he was a popular idol and the typical man of the "Fourth of July" period in American history. His countrymen easily forgave his faults and warmly admired his incontestable virtues. Extraordinarily illiterate, irascible in the highest degree, intensely patriotic, absolutely honest, terrible in the inflexibility of his purposes, faithful and devoted in his domestic life, a firm friend and implacable enemy, reckless and unflinching in the performance of what he conceived to be his duty, restless under any restraint calculated to hamper him in the discharge of that duty, an autocrat by nature yet a sincere lover of the common people,—such are some of the qualities which will always make Andrew Jackson one of the most picturesque figures in American history.

Bibliography.—Numerous biographies of Jackson exist. The best is still that by James Parton (3 vols., New York 1861); the life by Prof. W. G. Sumner in the 'American Statesman Series' is a careful study of his career as a public man (Boston 1883); the lives by John H. Eaton (Philadelphia 1817), and by Amos Kendall (New York 1843) have value as being written by men who knew him intimately. An excellent working bibliography for the study of Jackson's life and time will be found at the end of Professor Sumner's work.

W. N. C. CARLTON,
Librarian, Trinity College, Hartford.

Jackson, Charles Thomas, American scientist: b. Plymouth, Mass., 21 June 1805; d. Somerville, Mass., 28 Aug. 1880. He was graduated at Harvard Medical College in 1829, and practised for a time in Boston. He claimed to have been the first to indicate, in 1832, the applicability of electricity to telegraphic use, and also claimed, in 1842, to have been the discoverer of the anaesthetic effects of the inhalation of ether. He received the monthly prize of 2,500 francs from the French Academy of Sciences in 1852. He published a 'Manual of Etherization, with a History of its Discovery' (1861), and several 'Reports.'

Jackson, Edward Payson, American educator and author: b. Erzerum, Turkey, 15 March 1840. He was educated at Amherst College; served in the Union army during the Civil War as private of the 45th and lieutenant of the 5th Massachusetts; was principal and superintendent of various educational institutions, and in 1877 was appointed master in the Boston Latin School. His works include:

ANDREW JACKSON,
SEVENTH PRESIDENT OF THE UNITED STATES.

JACKSON

'Mathematical Geography' (1873); 'A Demigod' (1886), a story published anonymously, and at first attributed to various well-known authors; 'The Earth in Space' (1889); and 'Character Building' (1892), to which was awarded a prize of \$1,000, offered by the American Secular Union, jointly with N. P. Gilman's 'The Laws of Daily Conduct,' with which it was also published in the volume, 'Conduct as a Fine Art' (1894). He also became the editor of 'The Bohemian,' a Boston magazine of short fiction.

Jackson, Frederick George, English Arctic explorer: b. Alcester, Warwickshire, 1860. He was educated at Denstone College and the University of Edinburgh, made journeys across the Australian deserts and the Great Tundra of Siberia, in 1894-7 was leader of the Jackson-Harmsworth expedition to Franz Josef Land, and during the second Boer war was in command of a company of mounted infantry. During his stay in Franz Josef Land he mapped the region, which he proved to be a collection of islands, and made valuable magnetic and meteorological observations. He was awarded the gold medal of the Paris Geographical Society in 1899, and wrote: 'The Great Frozen Land' (1895); 'A Thousand Days in the Arctic' (1899).

Jackson, Gabrielle Emilie Snow, American writer for young people: b. New York 13 Oct. 1861. She was married to J. W. Jackson in 1886. Among her many publications are 'Denise and Ned Toodles' (1897); 'The Colburn Prize' (1899); 'Pretty Polly Perkins' (1900); 'Laddie and Lassie' (1900).

Jackson, George Anson, American Congregational clergyman: b. North Adams, Mass., 17 March 1846. He was graduated from Yale in 1868, from the Andover Theological Seminary in 1871, was ordained to the Congregational ministry, and in 1872-97 held pastorates successively at Leavenworth, Kan., Southbridge, Mass., and Swampscott, Mass. In 1897 he became librarian of the General Theological Library of Boston. He wrote: 'The Apostolic Fathers' (1879); 'Fathers of the Third Century' (1881); 'Post-Nicene Greek Fathers' (1883); 'Post-Nicene Latin Fathers' (1883); 'The Son of a Prophet' (1894), a historical novel.

Jackson, Helen Maria Fiske Hunt, 'H. H.' American novelist and poet: b. Amherst, Mass., 18 Oct. 1831; d. San Francisco, 12 Aug. 1885. At 21 she married Captain Edward Hunt (d. 1863) of the United States army, and began the wandering existence of an army officer's wife. From 1867 to her death, 16 years later, her pen hardly rested. She wrote verses, sketches of travel, essays, children's stories, novels, and tracts for the time, generally over the pen-name 'H. H.' Her life in the West after her marriage to W. S. Jackson, a banker of Colorado Springs, revealed to her the wrongs of the Indian, which she set herself at once to redress. Newspaper letters, appeals to government officialism, and finally her 'Century of Dishonor' (1881), a sharp arraignment of the nation for perfidy and cruelty towards its helpless wards, were her service to this cause. Her most popular story, 'Ramona' (1884), a romance whose protagonists are of

Indian blood, was also an appeal for justice. This book, however, rose far above its polemic intention; the beauty of its descriptions, its dramatic movement, its admirable characterization, and its imaginative insight entitling it to high rank. Two novels in the 'No Name Series'—'Mercy Philbrick's Choice' (1876) and 'Hetty's Strange History' (1877)—show the qualities that infuse her prose: color, brilliancy of touch, grace of form, certainty of intuition, and occasional admirable humor. She had not the gift of construction, and lacked the power of self-criticism; so that she is singularly uneven. It is no doubt chiefly her poems which have gained for 'H. H.' a place in literature. They reveal genuine lyrical power, although at times marred by defective technique. Among books of hers not already named are: 'Bits of Travel' (1873); 'Glimpses of Three Coasts'; 'Sonnets and Lyrics.' To her have often been attributed the noted 'Saxe Holm' stories.

Jackson, Henry Rootes, American diplomat and soldier: b. Athens, Ga., 24 June 1820; d. Savannah, Ga., 23 May 1898. He was graduated at Yale in 1839, admitted to the bar in Georgia and for several years was district attorney. He served in the Mexican War, became judge of the superior court, and in 1853 went to Vienna as *chargé d'affaires*, and the following year was made minister resident there. Before the outbreak of the Civil War he seceded from the Charleston Convention and, when his state seceded, joined the Federal army. He eventually resigned, and joined the Confederate forces. Near the close of the war he was made a brigadier-general in Hood's army and was captured with his whole command at Nashville after the battle of Franklin. In 1885 he was appointed United States minister to Mexico. He was the author of 'Tallulah, and Other Poems' (1850).

Jackson, Howell Edmunds, American jurist: b. Paris, Tenn., 8 April 1832; d. West Meade, Tenn., 8 Aug. 1895. He was graduated from the University of Virginia in 1854, from the law department of Cumberland University in 1856, began practice in Jackson, and later in Memphis, and upon the organization of the Confederate government became receiver for property in West Tennessee confiscated to the purposes of the Confederacy. Subsequent to the war he became a member of the court of referees of Tennessee, a tribunal which acted as a provisional supreme court in the hearing of cases that had arisen during the war period. Elected to the State legislature in 1880, he took his seat in the United States Senate in 1881, afterward left the Senate to become United States circuit court judge for the West Tennessee district, and in 1893 was appointed an associate justice in the United States Supreme Court.

Jackson, James, American soldier and statesman: b. Moreton Hampstead, Devonshire, England, 21 Sept. 1757; d. Washington, D. C., 19 March 1806. He emigrated to America with his father in 1772, and studied law in Savannah. In March 1776 he aided in repelling a British attack upon that town, and subsequently was appointed brigade major of the Georgia militia. In 1781 he aided in the capture of the fort at Augusta, and was left in command of

JACKSON

the place, and upon the evacuation of Savannah by the British in 1782 was appointed by General Wayne to receive the keys of the town. In 1789 he was chosen a representative in Congress, and from 1792 to 1795 was a member of the United States Senate. He had the principal share in the framing of the Georgia constitution of 1798, and upon its adoption was elected governor of the State, and held that office until his reelection in 1801 to the United States Senate.

Jackson, James, American physician, brother of Charles Jackson (q.v.): b. Newburyport, Mass., 3 Oct. 1777; d. 1867. He was graduated at Harvard College in 1796; studied medicine in London, and on his return to Boston in 1800 commenced practice there, devoting himself entirely to medical practice, to the exclusion of surgery and other branches. In 1803 he became a member of the Massachusetts Medical Society. In 1810, with Dr. John C. Warren, he brought before the community a proposition for establishing a hospital in the city of Boston. The first result of this was the organization of the asylum for the insane at Somerville, then included in Charlestown, and afterward of the Massachusetts General Hospital in Boston. Dr. Jackson was the first physician, and Dr. Warren the first surgeon, to this institution. In 1810 he was chosen professor of clinical medicine in Harvard, and in 1812 professor of theory and practice, becoming professor emeritus in 1835. His principal publications were: '*On the Brunonian System*' (1809); '*Remarks on the Medical Effects of Dentition*'; '*Letters to a Young Physician*' (1855). Of the last work several editions were printed.

Jackson, Patrick Tracy, American merchant, brother of Charles Jackson (q.v.): b. Newburyport, Mass., 14 Aug. 1780; d. Beverly, Mass., 12 Sept. 1847. At the age of 15 he was apprenticed to a merchant of Newburyport, and subsequently established himself in Boston in the India trade, in which he acquired a handsome fortune. In 1812, at the invitation of his brother-in-law, Francis C. Lowell, who had recently examined the process of the cotton manufacture in England, he engaged in a project to introduce the power loom, then newly invented, and the mode of constructing which was kept secret, into the United States. After repeated failures they succeeded in 1812 in producing a model from which a machine was subsequently constructed by Paul Moody. In 1813 they built their first mill at Waltham, near Boston, the first in the world that combined all the operations for converting the raw cotton into finished cloth. In 1821 Jackson made large purchases of land on the Merrimack River near the Pawtucket canal, on which a number of mills were constructed by the Merrimack Manufacturing Company, a corporation organized under his auspices. This settlement formed the germ of the present city of Lowell. He procured in 1830 a charter for a railroad between Lowell and Boston, the construction of which he directed until its completion in 1835.

Jackson, Samuel Macauley, American church historian: b. New York 19 June 1851. He was graduated from the College of the City of New York in 1870, from the Union Theolog-

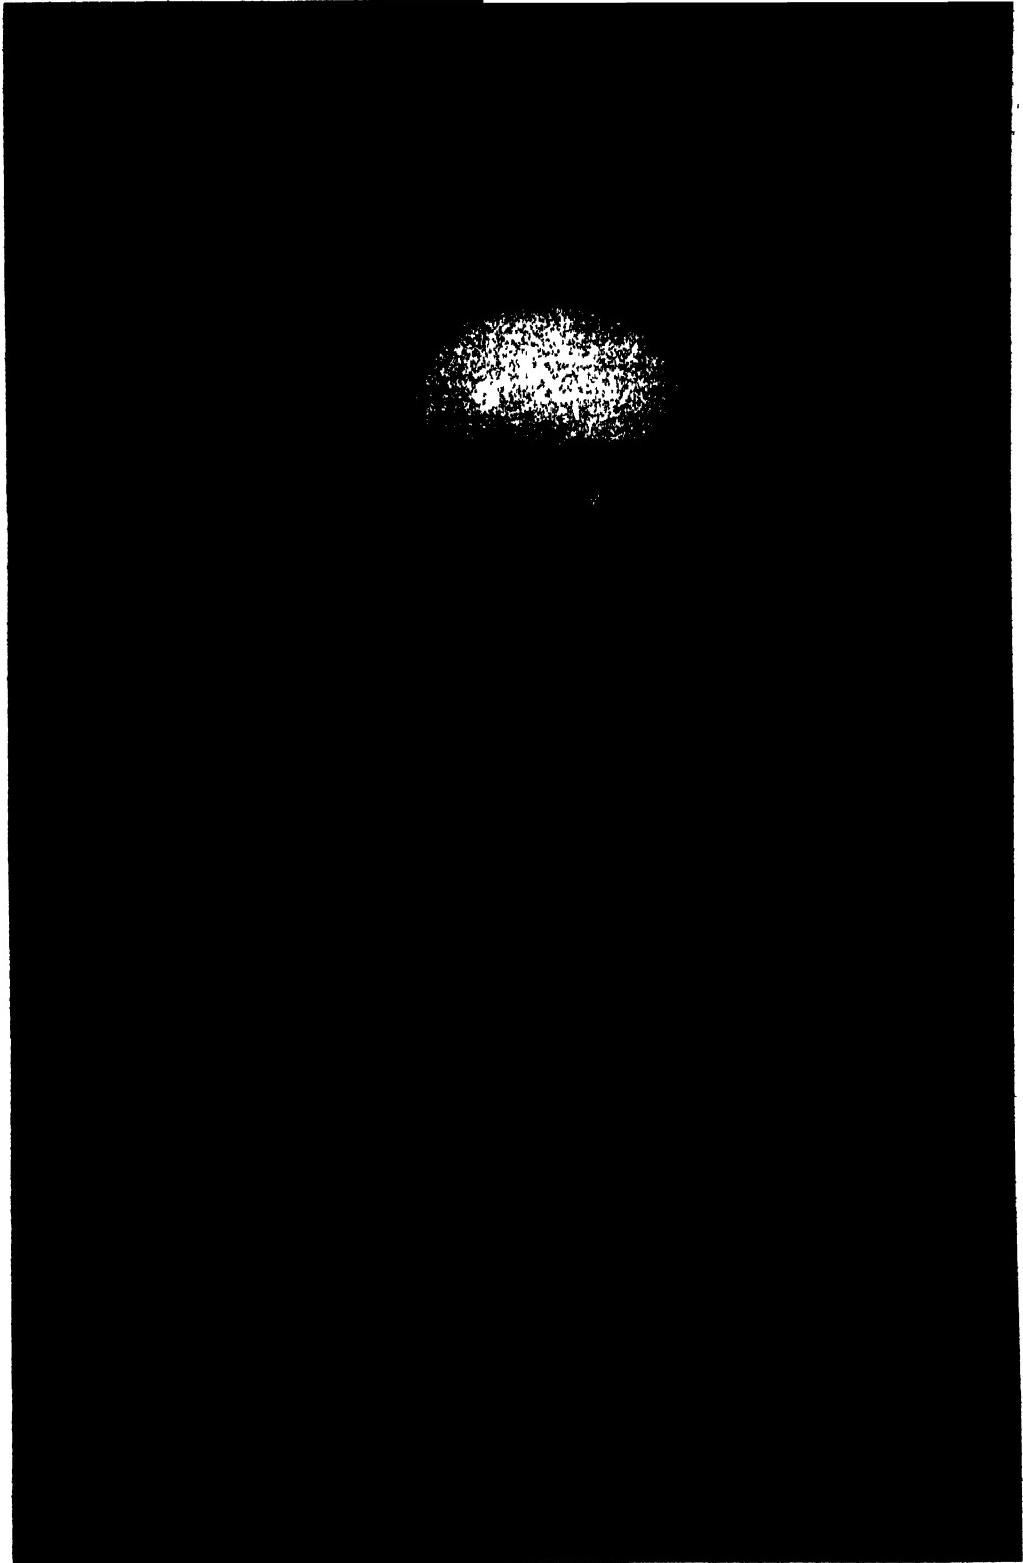

ical Seminary in 1873, and after further study at Leipzig (1873-6), held the pastorate of the Presbyterian Church at Norwood, N. J., in 1876-80. In 1895 he became professor of church history in New York University. He was assistant editor of Schaff's '*Bible Dictionary*' in 1878-80, associate and managing editor of the '*Encyclopædia of Religious Knowledge*' in 1880-4, and edited '*A Concise Dictionary of Religious Knowledge*' (1891). He also prepared the first important bibliography of foreign missions (1891), wrote '*Huldreich Zwingli*' (1901), the first original English biography of its subject, and was chosen secretary of the church history section of the American Historical Association.

Jackson, Sheldon, American educator: b. Minaville, N. Y., 18 May 1834. He was graduated at Union College in 1855, at Princeton Theological Seminary in 1858; was ordained to the ministry of the Presbyterian Church in the latter year; and was missionary to Western Wisconsin and Southern Minnesota in 1859-69. In 1869-82 he was superintendent of Presbyterian missions in western Iowa, Nebraska, the Rocky Mountain territories, Wyoming, Colorado, New Mexico, Arizona, Utah, and Montana, and from 1877 in Alaska. In 1885 he became United States general agent of education in Alaska, and in 1887 organized the Alaskan society of natural history and ethnology at Sitka. He aided in founding a Christian college in Utah in 1896, was moderator of the Presbyterian General Assembly in 1897, and wrote: '*Alaska and Missions on the North Pacific Coast*' (1880); '*Education in Alaska*' (1881); annual reports on '*Education in Alaska*' from 1886; and annual reports on the '*Introduction of Domestic Reindeer into Alaska*' (1891-1901).

Jackson, Stonewall. See JACKSON, THOMAS JONATHAN.

Jackson, Thomas Graham, English architect: b. Hampstead 21 Dec. 1835. He was educated at Oxford University and became the pupil of Sir George Gilbert Scott (q.v.) (1858-61), making a specialty of the Gothic style. He has designed most of the new buildings in Oxford, Cambridge, Eton, Westminster School, Rugby, Harrow, etc., and has restored Great Malvern Priory and Bath Abbey, besides building many new Gothic churches. He has written: '*Modern Gothic Architecture*' (1873); '*Wadham College, Oxford: its History and Buildings*' (1893); '*The Church of St. Mary the Virgin, Oxford: its History and Architecture*'.

Jackson, Thomas Jonathan, commonly called '*STONEWALL JACKSON*', American general: b. Clarksburg, Harrison County, Va., 21 Jan. 1824; d. near Chancellorsville, Va., 10 May 1863. Lieutenant-General Thomas Jonathan Jackson was one of the most unique, romantic characters of the War between the States, and crowded into the two years in which he served more brilliant achievements which won him wider fame than any other soldier on either side. Descended from Scotch-Irish stock and inheriting many of the qualities of his ancestry, he was left a penniless orphan when three years old, and soon showed "the stuff of which heroes are made," in his manly self-reliant efforts to

GEN. THOMAS J. (“STONEWALL”) JACKSON

JACKSON

support himself. Learning of a vacancy from his Congressional District in the military academy at West Point, he determined to make the journey to Washington and seek the appointment, and set out at once—traveling a part of the way on foot—appearing before the member of Congress from his district in his suit of homespun, and with his leathern saddlebags over his shoulders. The Congressman presented him to the secretary of war, who was so much pleased with the youth's determination that he at once made out his appointment to West Point. He was very badly prepared to enter the academy and barely "squeezed through" on his entrance examination, but by persevering work he gradually rose in his grade until in July 1846 he was graduated No. 17 in a brilliant class containing such men as McClellan, Foster, Reno, Stoneman, Couch, Gibbon, A. P. Hill, Pickett, Maury, D. R. Jones, Wilcox, and others; and one who knew him intimately expressed the confident belief that if the course had been longer "Old Jack" would have graduated at the head of his class. He immediately reported for duty in Mexico, and serving in the artillery won distinction on every field, always seeking the post of danger, being made first lieutenant at the siege of Vera Cruz, brevetted captain at Contreras and Churubusco, and major at Chapultepec, rising to this rank in seven months, and being promoted more rapidly than any other officer of his grade in the Mexican War. He was frequently and honorably mentioned in the official reports, and John B. Magruder, his immediate superior, wrote of him: "If devotion, industry, talent, and gallantry are the highest qualities of a soldier, then he is entitled to the distinction which their possession confers." In the City of Mexico, after its capture and occupation, he had under the influence of that earnest Christian soldier, Colonel Taylor, become deeply concerned on the subject of personal religion and made a profession of faith in the Lord Jesus Christ. At West Point he had adopted as his motto: "You may be whatever you resolve to be," and now he added to this motto the saying of the great Apostle: "I can do all things through Christ which strengtheneth me." These two mottoes were the keynotes of his life and led the penniless orphan boy to become one of the immortals.

On the earnest recommendation of his old comrade, D. H. Hill, whose brother-in-law he afterward became, Jackson was elected, in 1851, professor of natural science and instructor of military tactics in the Virginia Military Institute, Lexington, Va., being elected over McClellan, Reno, Rosecrans, and G. W. Smith, whose names were submitted by the faculty at West Point. He made little reputation as a professor, for while thoroughly acquainted with his subject he lacked that "aptness to teach" so essential to a successful teacher, and the cadets were always playing pranks upon him, and laughing at his eccentricities. But he became one of the most consecrated active members of the Presbyterian Church, and left his impress as a Christian upon the community. From his habit of instructing his own servants in Scripture lessons every Sunday afternoon grew his famous negro Sunday school to which he devoted so much time and thought, to which he contributed so liberally of his moderate means,—sending his pastor checks for it in the

midst of his most active campaigns,—and which made such an impress upon the negroes and gave Jackson so warm a place in their affections that the first contribution to his monument was made in 1887 by the negro Baptist Church of Lexington. Jackson was a Union man, opposed to secession as a remedy for Southern wrongs, though thoroughly believing in the abstract right of a State to secede, and greatly deprecated the war which he predicted would follow; but when the news reached the quiet little town of Lexington that Mr. Lincoln had called for 75,000 troops to coerce sovereign States, and that the Union Convention of Virginia had passed an ordinance of secession, Jackson said in a speech before a public meeting: "I have longed to preserve the Union and would have been willing to sacrifice much to that end. But now that the North has chosen to inaugurate war against us, I am in favor of meeting her by drawing the sword and throwing away the scabbard." Governor Letcher, his old neighbor and friend, who had a high estimate of his abilities, commissioned him colonel in the Virginia forces; but his brilliant record in Mexico had been forgotten—he was only thought of as the quiet, eccentric professor, and when his name was presented to the Virginia convention, a prominent member arose and asked: "Who is this Major Jackson, anyway?" and it required all the eloquence of the Rockbridge delegates to secure his confirmation.

Marching the corps of cadets to Richmond where he remained for a brief season assisting in organizing and drilling the raw recruits in the "Camp of Instruction," he was ordered to Harper's Ferry on 3 May, where the skill he showed in reducing the high-spirited rabble who had rushed to the front at the first sound of the bugle to the respectable Army of the Shenandoah, which he turned over to the command of General J. E. Johnston 23 May, showed clearly that he was a soldier. Placed in command of the Virginia brigade which afterward became so famous, he met the advance of General Patterson at Falling Waters on 2 July, gave them a decided check, and captured a number of prisoners. Soon after he received his commission as brigadier-general in the following characteristic letter from General Lee:

RICHMOND, 3rd July, 1861.

MY DEAR GENERAL:—I have the pleasure of sending you a commission of brigadier-general in the Provisional Army; and to feel you merit it. May your advancement increase your usefulness to the State.

Very truly,

R. E. LEE.

But it was in the battle of first Manassas (Bull Run) that Jackson won his new name and fame, and the ringing words of the gallant Bee: "There stands Jackson like a stone wall," changed the name of "Thomas Jonathan" into the immortal "Stonewall" Jackson. He was wounded in the hand but refused to leave the field, and while the surgeons were dressing his wounds President Davis rode on the field, and Jackson, pushing aside the surgeons, tossed his cadet cap in the air and exclaimed: "Hurrah for the President. Give me ten thousand men and I will be in Washington to-night!" In September he was made major-general, and was sent on 4 October to command the "Valley District" and enter in the early part of 1862

JACKSON

on that famous "Valley Campaign," which is now studied in military academies in Europe as illustrative of able strategy, rapid movements, and heroic fighting. In March he fell back before Banks' army of 35,000 men, and Banks reported him "in full retreat from the valley" and started a column to cross the mountains and attack Johnston in flank as he was falling back from Manassas, when Jackson suddenly turned, marched 18 miles in the morning, and with 2,700 men fought at Kernstown, near Winchester, 8,000 of the enemy, and though sustaining the only defeat that ever befell him he accomplished his purpose in recalling the column which was moving on Johnston's flank, quietly moved up the valley and took a strong position in Swift Run Gap from which he could easily defend himself or strike the enemy if he attempted to move on Staunton. Ewell's division coming to take his place, he left this grim soldier to watch Banks, and moved so secretly that neither friend nor foe had divined his plans until he thrilled the Confederacy and sent terror to the North by the following laconic and characteristic despatch:

Valley District, May 9th, 1862.

GEN. S. COOPER:—God blessed our arms with victory
at McDowell yesterday.

T. J. JACKSON, Major-General.

He had defeated the advance of Fremont under Milroy and driven it back in great confusion. Then followed in rapid succession the uniting of Ewell's division with his at Luray, the driving in of Banks' flank at Front Royal, the cutting of his retreating column at Middletown, and on 25 May the rout of Banks' army from the heights of Winchester, and driving him pell-mell across the Potomac. He was about to cross the Potomac into Maryland in pursuit of Banks when he learned that Fremont from the West, and Shields, the head of McDowell's column, from the East, were marching to form a junction in his rear at Strasburg. He at once put his army in motion and by forced marches (one of his brigades marched 52 miles in one day) he reached the point of danger in time to hold Fremont in check with one hand and Shields with the other until his whole army, prisoners, and immense wagon trains loaded with captured stores passed on in safety. He then moved leisurely up the valley, burning the bridges over the Shenandoah to prevent a junction between Fremont and Shields—his rear being protected by that chivalrous knight and brave soldier, General Turner Ashby, who filled the valley with the fame of his brilliant achievements, and whose fall in a severe fight near Harrisonburg on 6 June was sadly lamented as a great calamity to the Confederate cause. On 7 June, at Cross Keys, Ewell badly defeated Fremont, and on 8 June, at Port Republic, on the opposite side of the river, Jackson routed Shields, and the armies sent to "crush" him were soon rapidly retreating down the valley, while "Stonewall"—that name will cling to him, but "Thunderbolt," "Tornado," or "Hurricane," would be more expressive of his character,—remained master of the situation. This campaign may be thus summarized: In 32 days Jackson and his "foot cavalry" had marched nearly 400 miles, skirmishing almost daily, fought five battles, defeated three armies, two of which were completely routed, captured 20 pieces of artillery, 4,000 prisoners, and immense

quantities of stores of all kinds, and had done all this with a loss of fewer than 1,000 men killed, wounded, and missing, and with a force of only 15,000 men, while there were at least 60,000 men opposed to him. He had spread consternation throughout the North and had neutralized McDowell's 40,000 men at Fredericksburg, who were about to march to the aid of McClellan in investing Richmond. Jackson now rested for a brief season, was reinforced from Lee's army, made the impression on the enemy that he would advance down the valley again, and managed matters so secretly that Banks at Strasburg was busily engaged in fortifying against an expected attack from him at the very time he was thundering on McClellan's flank at Richmond over 200 miles away. The part he bore in the Seven Days around Richmond, the second Manassas campaign, and the Maryland campaign was so conspicuous and so important that it would be, indeed, to write the history of the army to give it in detail. His skill and daring in the Seven Days battles, his defeat of Pope's advance under Banks at Cedar Run, his flank march to Pope's rear, and the pertinacity with which he held him at bay along the Warrenton road until Lee could come up with Longstreet and drive him into the fortifications around Washington, his capture of Harper's Ferry with 11,000 prisoners, 13,000 stand of small arms, 73 pieces of artillery, and large quantities of provisions and stores of every description, and his conduct on the field of Sharpsburg, all added greatly to the fame of Stonewall Jackson and his grand old corps of "Foot Cavalry." It was the privilege of the writer of this sketch to be under Jackson during the whole of his brilliant career, and it may not be amiss to describe him as he appeared at the head of his victorious legions: About 37 years old, six feet high, medium size, gray-blue eyes, light brown hair, a rough mouth, iron jaw, and nostrils as big as a horse's. He wore a plain gray uniform which soon became faded and soiled, cavalry boots, and an old gray cadet cap with its rim tilting on his nose. He rode a raw-boned sorrel horse which the men said "could not run except toward the enemy," but whenever he appeared among the troops they would begin to give the Confederate yell, and he would take off his cap, put spurs to "Little Sorrel" and gallop away from them as rapidly as possible. This was so well understood that, when cheering was heard, some soldier would say: "There comes old Stonewall, or an old hare, one," and it was said that "the appearance of those personages never failed to elicit the genuine old Confederate yell." On 10 Oct. 1862 he was made lieutenant-general, and his corps made to consist of his old division, under W. B. Taliaferro, Early's division, A. P. Hill's division, and D. H. Hill's division, Colonel Brown's regiment of artillery, and numerous light batteries. At Fredericksburg, 13 Dec. 1862, he held the extreme right of Lee's army, and defeated with great slaughter Franklin's attack upon him. The following winter and spring Jackson spent in improving the organization, discipline, and efficiency of his corps, and as, in his judgment, a most important means of accomplishing this, he labored to have chaplains in every regiment and missionaries to visit the army, and did everything in his power to promote the religious welfare of his soldiers. It was largely through

JACKSON

his influence that a chaplains' association was formed, and he had regular prayer-meetings at his headquarters during the weeks and preaching on Sundays. One of the most impressive scenes ever witnessed was one of these preaching services at Jackson's headquarters, where would be gathered from 2,000 to 3,000 soldiers, among whom might be seen R. E. Lee, R. S. Ewell, A. P. Hill, J. A. Early, R. E. Rodes, J. B. Gordon, J. E. B. Stuart, Taliaferro, Battle, Heth, Wilcox, Pender, and many other generals and colonels, and other field, staff, and company officers,—the rough garb of the private soldier mingling with the bars and stars, and wreaths of rank,—and prominent in the crowd "Old Stonewall" himself "playing sexton" in seeing the crowd seated, and profoundly interested in the services.

A man of prayer, a student of God's word, an implicit believer in the promises of the Bible, in an overruling Providence, a consecrated, humble, active Christian, he was, indeed, "a living epistle, known and read of all men," and eternity alone will reveal how far the great revivals in Lee's army, through which over 15,000 of the soldiers were brought to profess faith in Christ, were in answer to the prayers, and in blessing upon the labors of this great "Soldier of the Cross," as well as soldier of his country. But the end hastened on, General Hooker threw Sedgwick across the river below Fredericksburg the latter days of April 1863, crossed the bulk of his army above and strongly fortified his lines at Chancellorsville in the confident hope that Lee would either retreat on Richmond, or attack him in his strong position, where a crushing defeat would await him. But instead of doing either of these things Lee left Early to watch Sedgwick, moved up to Hooker's front, and sent Jackson with 22,000 men to make a march to Hooker's flank and rear. This was brilliantly executed and Jackson routed that flank of Hooker's army, and was proceeding to cut him off from his line of retreat and take a position where Hooker would have been compelled to attack him, when in returning from one of those bold reconnoisseances which he so frequently made, his party was mistaken for the enemy and fired on by his own men and he was very severely wounded. His left arm was amputated, his other wounds dressed, and he was doing well and gave every promise of recovery, when pneumonia, brought on by exposure before the battle, set in and he died at a quarter past three P.M., Sunday, 10 May 1863.

Calm, peaceful, trustful, in his lucid hours he talked cheerfully of his approaching end,—said that it would be "infinite gain to be translated and be with Jesus," and that "it was all right," and that he would have his cherished wish in dying on Sunday,—then his mind wandered to the battle-field and he exclaimed: "Tell A. P. Hill to prepare for action." "Pass the infantry rapidly to the front!" "Tell Major Hawks —," and then with a sweet smile, he said: "Let us cross over the river and rest under the shade of the trees!" The great soldier had fought his last battle, won his last victory, and gone to wear his glittering "crown of rejoicing." He was buried as he had requested, in "Lexington in the valley of Virginia;" a beautiful bronze statue marks his grave; on the hill at the Virginia Military Insti-

tute has been reared the stately "Jackson Memorial Hall," and in the capitol square of his native State stands the noble bronze statue, the gift of English admirers. Lee spoke his fittest eulogy when he wrote him after hearing that he was wounded: "Could I have dictated events I should have chosen for the good of the country to have been disabled in your stead." The American and the English press have written him down as one of the greatest soldiers of history, and other nations have endorsed these estimates, while future generations will tell to their children the story of Jackson's life and hold up for their example and imitation the penniless orphan boy who became one of the immortals.

J. WM. JONES,
Author and Lecturer.

Jackson, William Hicks, American soldier and stockman: b. Paris, Tenn., 7 Oct. 1836; d. Nashville, Tenn., 30 March 1903. He was graduated from West Point in 1856, was on frontier duty in the mounted riflemen in 1857-61, resigned from the service in 1861, entered the Confederate army as captain of artillery, and rose to be brigadier-general. Subsequent to the war he was proprietor of the Belle Meade stock-farm, near Nashville, Tenn., which sent to the races some of the greatest running horses of the American turf. He was president of the National Agricultural Congress, and high in the councils of the southern Democracy.

Jackson, Mich., city, county-seat of Jackson County; on the Grand River, and on the Lake Shore & M. S., the Cincinnati N., the Michigan C., and the Grand T. R.R.'s; about 35 miles south of Lansing and 72 miles west of Detroit. The first permanent settlement was made in 1829, and for some years it was the trade centre for a number of the large lumbering camps and for the scantily settled country in Jackson and the adjoining counties. After the Michigan Central railroad was put through the southern part of the State, in 1841, Jackson grew rapidly, and in 1857 it was chartered as a city. The country around is a rich agricultural region, noted for its fruits, grains, and vegetables. Coal and clay, the latter useful for pottery, are found nearby. The chief manufactures are flour, paper, machine-shop products, corsets, wagons, carriages, foundry products, agricultural implements, bricks, and sewer-pipe. Its trade consists principally in agricultural products, articles from the local industrial establishments, and in reaping and mowing machines, goods for clothing, and groceries. The car shops of the Michigan Central railroad are in Jackson. The city owns and operates the waterworks. Its rapid growth is due, to a large extent, to the development of its manufacturing industries. Pop. (1890) 20,798; (1900) 25,180.

Jackson, Miss., capital of the State, county-seat of Hinds County; on the Pearl River, and on the Yazoo & M. V., the Illinois C., and the Alabama & V. R.R.'s; about 40 miles east of Vicksburg, on the Mississippi. The first permanent settlement was made in 1828, or 1829, and it was incorporated in 1840. In 1863 it was occupied for some time by Union forces under Gen. Grant, and the ruins of the fortifications erected at the siege are still in existence.

JACKSON

The city was nearly destroyed in 1864, by Gen. Sherman.

Jackson is situated in an agricultural region in which a large amount of cotton is raised. It is the commercial centre for a large section. The good railroad facilities and the advantage of traffic on the Pearl River are stimulating the increase of marketable agricultural and manufactured products. The chief industrial establishments are cottonseed-oil mills, fertilizer factories, sash, door, and blind factories, foundries, brick-yards, a cotton-compress, a plow and harrow factory, a broom factory and cooper shops. Some of the principal public buildings are the State capitol, State charitable institutions for the blind, insane, deaf and dumb, the State library, and the James Observatory. Among the private educational institutions of learning are the Millsaps College, founded in 1892 under the auspices of the Methodist Episcopal Church; and the Bellhaven College for young ladies. Pop. (1890) 5,920; (1900) 7,816; (1903) 12,000.

Jackson, Ohio, city, county-seat of Jackson County; on Salt Creek, and on branches of the Baltimore & O. S. W., the Hocking V., and the Ohio S. W. R.R.'s; about 100 miles east of Cincinnati and 70 miles southeast of Columbus. Jackson is located in the vicinity of the early routes of travel from the Ohio River to the interior of what is now the State of Ohio, and on to the Great Lakes. The first permanent settlement was made in 1795, but it was not incorporated until 1847, several years after the limits of Ohio were decided. It is situated in a coal and iron mining section, but there is a large amount of good farming land in the vicinity. The chief industrial establishments of the city are foundries, machine-shops, furnaces, woolen-mills, a tannery, and lumber-yards. The coal and iron ore-mining of the vicinity contributes largely to the industrial wealth of the city. Pop. (1900) 4,672.

Jackson, Tenn., city and county-seat of Madison County, situated about 80 miles northeast of Memphis, on the South Fork of the Forked Deer River, and on the Illinois C., Mobile & O., and Nashville, C. & St. L. R.R.'s. It is the trade centre of a large and fruitful agricultural region, is an important cotton market, and has manufactures of engines and boilers, cotton goods, lumber, machinery, flour, cottonseed-oil, furniture, trunks, spokes and skewers, plows, carriages, bricks, and other products. Here are located the Southwestern Baptist University, the Memphis Conference Female Institute, and Lane University. Jackson has a fine park, Carnegie Library, and modern municipal improvements, the waterworks and electric-light system being owned by the city. It has five banks with a combined capital of \$400,000. The government is by mayor and a council of eight aldermen. Jackson was first settled in 1818. Pop. (1900) 14,511.

During the Civil War Jackson was at times the headquarters of Gen. Grant. It was captured by Union troops 7 June 1862. On 19 Dec. 1862, Gen. Forrest sent detachments of cavalry to destroy the railroad to the north and south, and with 400 men advanced on Jackson and had a running fight with two regiments of Union infantry and detachments of cavalry under Col. Engelmann of the 43d

Illinois, who disputed Forrest's advance until the fortifications of the town were reached, when Forrest withdrew and moved on Humboldt and Trenton. On 13 July 1863, a Confederate cavalry force held the town and guarded a large number of conscripts. Col. Edward Hatch with 1,160 men of the 3d Michigan, 2d Iowa, 1st West Tennessee, and 9th Illinois cavalry regiments attacked the Confederates and drove them from the town, releasing about 450 conscripts, and capturing 250 horses and nearly 400 stand of small arms. Hatch's loss was very slight. The Confederates had 38 killed and about 150 wounded. Consult: 'Official Records,' Vol. XXIII.

Jackson (Miss.), Battle of. After the battle of Raymond (q.v.), 12 May 1863, Gen. Grant, having provided for the safety of his rear and left from the direction of Vicksburg, turned McPherson's and Sherman's corps and part of McClelland's on Jackson, 12 miles northeast of Raymond, to capture the place without delay. On the 13th McPherson moved from Raymond to Clinton, and then turned east on Jackson. Sherman moved through Raymond to Mississippi Springs on the 13th, and that night arranged with McPherson that both columns should arrive at Jackson about the same hour next day. McClelland closed up to Raymond and sent one division to Clinton to support McPherson. Gen. J. E. Johnston had arrived at Jackson on the evening of the 13th and, hearing next morning of the Union approach on the Raymond and Clinton roads, ordered Gregg's brigade to take position on the first-named road, and Walker's brigade on the latter, with instructions to each to delay the Union advance as long as possible, to give time for the removal of public property from the city. The combined strength of Gregg and Walker was about 6,000 men. About 9 A.M. of the 14th McPherson's advance on the Clinton road came upon Walker's pickets and drove them back upon the main body, posted in works on the crest of a semi-circular ridge 2½ miles west of Jackson, the front covered by a marshy creek lined with dense willows, and artillery commanding the bridge over the creek. At the end of nearly two hours Crocker's division of three brigades was deployed in line, with one brigade of Logan's in reserve. At 11 A.M. the skirmishers advanced to the creek and were checked, upon which the entire division went forward, drove in Walker's skirmishers, and advanced over the open ground beyond the creek, meeting a stout resistance; but Walker's men soon retreated, abandoning seven guns. They were pushed more than a mile by Crocker; but his men fell into some disorder, and were finally brought to a stand by artillery posted in an inner line of works close to the town. While Crocker was reforming, Walker made his escape to the Canton road. Crocker's loss was 265 killed and wounded. On the Raymond road Sherman encountered Gregg and, by a flank movement, compelled him to abandon his entire line and ten guns, with the loss of nearly 200 prisoners and 81 in killed and wounded. Sherman's loss was 32. Johnston retreated northward on the Canton road. McPherson and Sherman entered Jackson between 3 and 4 P.M.; Sherman was left in the city to destroy the railroads, bridges, factories, arsenals, and everything valuable. On the morn-

JACKSON — JACKSONVILLE

ing of 15th Grant turned the rest of his army west, defeated Pemberton at the battle of Champion's Hill (q.v.) on the 16th, drove him across the Big Black on the 17th, and began the siege of Vicksburg. The Union loss at Jackson was 42 killed, and 251 wounded. The Confederates make their loss less than 400, but Sherman estimated it at 845 killed, wounded and missing. Consult: 'Official Records,' Vol. XXIV.; Johnston, 'Narrative'; Sherman, 'Memoirs,' Vol. I.; The Century Company's 'Battles and Leaders of the Civil War,' Vol. III.

E. A. CARMAN.

Jackson, Siege of. The battle of Jackson (q.v.), 14 May, 1863, was followed by the movement of Gen. Johnston northwest, with Gregg's and Walker's brigades, to form a junction with Pemberton, who had been directed to join him; but early on the 19th he received word from Pemberton that he had decided to hold Vicksburg instead, upon which Johnston marched his troops to Canton. He was reinforced, and 29 June he marched west to operate in the rear of Grant, who was besieging Vicksburg. He was about to move on the morning of 5 July to the south of the Vicksburg and Jackson Railroad, when he heard that Vicksburg had fallen, whereupon he fell back to Jackson and occupied a line of works covering the town, with both flanks on Pearl River. Gen. Sherman had been held in readiness to move back and drive the Confederates from the State, and when Vicksburg fell he moved promptly with his own corps and those of Gen. Ord and Parke, crossed the Big Black at three different points, and by 11 July was close up to Johnston's works and shelling the city with nearly 100 guns. Ord's Thirteenth corps was on the right, the Fifteenth corps in the centre, and Parke's Ninth corps on the left. On the 12th the fire of the artillery was increased, reaching every part of the town, and Lauman's division of Ord's corps, moving in dense woods, came too close to the Confederate works, was struck in flank and driven back in disorder, losing over 500 men killed, wounded, and captured, together with the colors of three regiments. The siege was prosecuted night and day, and on the morning of the 17th Jackson was found evacuated, Johnston having retreated on the road to Brandon, and thence to Morton, where he arrived on the 20th. Steele's division pursued Johnston as far as Brandon, 14 miles from Jackson; Sherman remained five days at Jackson, destroying much property of every description, and then returned to Vicksburg. The Union loss at Jackson, 11–16 July, was 129 killed, 762 wounded, and 231 missing or captured. The Confederate loss, 5–25 July, was 71 killed, 504 wounded, and 764 captured or missing. Consult: 'Official Records,' Vol. XXIV.; Johnston, 'Narrative'; Grant, 'Memoirs,' Vol. I.; Sherman, 'Memoirs,' Vol. I.; The Century Company's 'Battles and Leaders of the Civil War,' Vol. III.

E. A. CARMAN.

Jacksonville, Fla., one of the most important and rapidly growing ports of the southeastern United States; chief city of the State, and seat of Duval County in the northeastern corner; on the west bank of the St. John's, 24 miles from the ocean by water, 14 direct. It is one of the chief southern railroad centres, six important lines converging there, three of them great trunk lines: the Southern, Seaboard Air

Line, Atlantic Coast Line, Georgia Southern & Florida, Florida East Coast, and Jacksonville & Southwestern. It is 138 miles south of Savannah, 212 north of Tampa, and 165 east of Tallahassee; and about 1,000 from New York, with train service of 25 to 28 hours. It is also connected with all the Atlantic coast cities by the Clyde, Mallory, and Ocean Steamship lines; and with the picturesque St. John's and its tributaries by six daily and tri-weekly lines of steamers. The fascinating rivers, lakes, Everglades, etc., of Florida, the best hunting and fishing grounds east of the Mississippi, with Jacksonville's mild and healing winter and even summer climate, make it one of the leading tourist resorts in the country, some 50,000 to 60,000 stopping annually at its numerous large and well-equipped hotels.

Jacksonville's position makes it the business key and metropolis of the peninsula, the great shipping point for Florida's exports, and the distributing point for its purchases. Of the former, the chief are lumber, shingles, and ties, mainly yellow pine from the great Florida forests, to nearly \$2,000,000 a year; next come naval stores — turpentine, rosin, and rosin oil — of over \$1,000,000, and rapidly increasing, a company with \$3,000,000 capital having been recently organized for it; cotton has also risen to over \$600,000 a year; and an extremely heavy element is the shipping of fruit — oranges, pineapples, and a great diversity of tropic fruits, for which see FLORIDA — and garden vegetables to the North. In a suburb of the city is the largest ostrich farm in the United States, and the only one east of California, whose products form part of the shipments; these also include great quantities of phosphates and fertilizers, and kaolin. As a jobbing centre for interior trade, it has the immense advantage of having practically no competitor in the State, and is rapidly becoming one of the foremost in the South; there are 19 large wholesale grocery houses alone, and the freight entries of grain, hay, and milled products amounted in 1900 to over \$12,000,000. Its gross annual trade exceeds \$75,000,000. This business implies large banking facilities; and there are now two national and three State banks in the city, besides a savings bank, with over \$1,100,000 of capital and undivided profits.

In manufacturing, Jacksonville's chief specialty is lumber and timber products, which in 1900 amounted to nearly a third of the entire output of \$2,312,300; there are ten large saw and planing mills. Of the other industries, the most considerable was the manufacture of ice, five establishments producing \$87,647 worth; a witness to the needs of thronging tourists in a warm climate. But there were also foundry and other iron products, steam engineering works, brick and tile, paving and roofing materials, wooden ship and boat building, carriages, saddlery, mattresses and palmetto fibre products, pulp, patent medicines, confectionery, cigars, and other articles. There are about 200 different establishments in all.

As a port, it has long been hampered by shoals in the river, and the bar outside the St. Johns. The river is a magnificent estuary, a mile wide for many miles up, and with a channel deep enough for the largest ocean vessels; but it

JACKSONVILLE—JACOB TOME INSTITUTE

was not until 1896, by combined government and local efforts, that a channel 19 feet deep was obtained from Jacksonville to the ocean, admitting vessels of 3,800 tons. The National government, at last, in 1901, appropriated \$1,300,000 to deepen it to 24 feet all the way, by a permanent system of jetties and dredging. It has over seven miles of water front. The city, 7.6 square miles in area, is handsomely laid out, and its business section is almost entirely new, having been practically obliterated by a fire on 3 May 1901, which destroyed 148 blocks, covering 455 acres and including 2,361 buildings, a property loss of over \$15,000,000. With astonishing energy up to 25 Oct. 1903, 3,361 new buildings had been erected, 1,000 more than were destroyed, and greatly improved ones. Among the finest buildings are the Union station, United States post-office and custom-house, Masonic Temple, St. Luke's hospital, National Bank of Jacksonville (which were spared by the fire). Among the public buildings since erected are the Windsor hotel, Seminole, Elks, Woman's and Wheelmen's club-houses, Mercantile Exchange Bank, Board of Trade, and Duval High School. A \$50,000 Carnegie free library is being erected. The religious denominations have built a number of fine churches, costing from \$25,000 to \$100,000 each. Notable among them are the Congregational, Baptist, Christian, McTieire Memorial (M. E. South), Snyder Memorial (M. E.), Presbyterian, St. John's Episcopal, Church of Good Shepherd, Episcopal, and three fine colored churches. There are five parks of 57 acres in all, "Hemming" having a Confederate monument; and 14 miles of shell streets and drives, besides a general macadamizing of paving with vitrified brick. The ocean beaches, 18 to 20 miles off, are among the finest on the Atlantic coast. The sanitation of the city is perfect. After the yellow fever epidemic of 1888 it installed a fine thorough system of sewerage, drained and filled in the swampy tracts around, and replaced the water supply with one almost chemically pure, drawn from artesian wells 500 to 1,000 feet deep. Its death rate has sunk to 10 in 1,000, one of the lowest in the country. There are 20 miles of trolley tracks, and the city owns electric-light works and waterworks; both light and water are extremely cheap. The finances of the city are in the best condition. It has never defaulted its bonds, which are for the waterworks and electric plant, and amount to \$1,368,000, payable 15 May 1904 at 5 per cent. There is no floating debt. The assessed valuation is \$15,000,000; tax 16.02 mills on the dollar, or 11 mills if beyond the hydrants. Jacksonville was settled in 1816 by Lewis Z. Hogans, whence Hogans' Creek, dividing the city, is named. In 1822 it was laid out and named after Andrew Jackson, the first territorial governor of Florida. It was incorporated in 1833. The Seminole War prevented its development, but it revived in 1842 and has grown steadily since. Its population in 1850 was 1,045, in 1860 2,118, in 1870 6,912, the war having been an immense gain instead of loss; 1880 7,650, 1890 17,201, 1900 28,429, of whom 16,271 or 57 per cent were colored. At present (1903) is over 35,000.

CHAS. H. SMITH,
Secretary Jacksonville Board of Trade.

Jacksonville, Ill., city, county-seat of Morgan County; situated on the Mauvaisterre Creek, a branch of the Illinois River, about 34 miles southwest of Springfield and 88 miles north of St. Louis, Mo.; on branches of the Wabash, the Chicago & A., the Burlington, the Chicago, P. & St. L., and the J. & St. L., the last of which is also a part of the Burlington system. Jacksonville was laid out as early as 1825, about seven years after the admission of the State of Illinois into the Union, established as a town in 1840, and incorporated as a city in 1867. It was made the county-seat of Morgan County in 1825. The origin of the name of the city is somewhat uncertain, but the most probable tradition seems to indicate that it was named in honor of Andrew Jackson, who was a prominent Presidential candidate at the time when the town was founded. Jacksonville is noted for its institutions of learning, its wide, prettily shaded streets, and its handsome residences. It is the seat of Illinois College, the oldest college in the State, founded through the efforts of local residents and a band of students from Yale College. Originally non-sectarian, the college has recently become Presbyterian, has absorbed the Jacksonville Female Academy, and become affiliated with the University of Chicago. Among the other institutions are: the Illinois Woman's College, established in 1847 under the auspices of the Methodist Episcopal Church; the State Central Hospital for the Insane; the State School for the Blind; the State School for the Deaf and Dumb; Our Saviour's Hospital, in charge of the Sisters of the Holy Cross; the Passavant Memorial Hospital; a Carnegie Free Public Library; the Conservatory of Music; and Whipple Academy, a preparatory school. The last two are connected with Illinois College. The city-hall, the court-house, and the high school are the most prominent public buildings. Besides these, there are numerous church edifices, the most attractive of which is the Westminster Presbyterian. The most important industrial establishments of the city are the woolen mills, and the car-shops of the Chicago, Peoria & St. Louis Railroad. Other manufactures include machine-shop products, bricks, candy, paper, and flour. The executive head of the city government is a mayor, who holds office for two years, and a city council composed of 12 members elected for two years by the four wards. The mayor appoints the administrative officials, subject to confirmation by the council. The city owns and operates the electric-light plant and the waterworks. Pop. (1890) 12,935; (1900) 15,078.

C. H. RAMMELKAMP,
Head of Department of History and Political Science, Illinois University.

Jacob (Heb. *Yaqôbh*, the supplanter), the son of Isaac, and the grandson of Abraham, the last of the Jewish patriarchs, and the real ancestor of the Jews. He died at the age of 147 years, about 1860 B.C., and was buried in the tomb of Abraham, before Mamre in Canaan.

Jacob Tome Institute, an institution of secondary education located at Port Deposit, Md. It was founded 1894 by Jacob Tome. When Mr. Tome's gift was made, only five other citizens of the United States—Stephen Girard, Anthony J. Drexel, Johns Hopkins,

JACOBI—JACOBITES

Charles Pratt, and John D. Rockefeller — had made greater gifts to educational institutions. The endowment and other property of the school are estimated at more than \$3,000,000. The Jacob Tome Institute was incorporated in 1889. The boarding school for boys, founded in 1900, is located on the hills overlooking the historic Susquehanna River. The grounds of the institute include about 160 acres. The principal buildings are Memorial Hall, erected in memory of the founder, two dormitories, gymnasium, the Inn, power plant, and infirmary. The school consists of six classes, each requiring one year. The studies of the last three years are arranged in five groups which prepare students for college, technical schools, or for active business life. The institute confers no degrees, although a certain amount of collegiate work can be and is done in the regular courses. Students must be not less than 10 years of age in order to gain admission. Special scholarships are offered to boys from Maryland. There is also a kindergarten, Junior School, and Senior School for girls.

Jacobi, ja-kō'bī, Abraham, American physician: b. Hartum, Westphalia, 6 May 1830. He was educated at the Universities of Greifswald, Göttingen, and Bonn, and was graduated as M.D. from the latter in 1851. Those were years of revolutionary ferment in Germany and Jacobi, becoming identified with the movement, was held in detention for "high treason" at Berlin and Cologne (1851-3). In 1853 he settled in practice in New York, where his abilities soon brought him into notice. He was appointed professor of diseases of children at the New York Medical College (1860-5) and held a similar chair in the medical department of the University of the City of New York (1865-70). Some years later he became professor of the diseases of children at the College of Physicians and Surgeons. He has held many important appointments and was president of the New York State Medical Society (1882) and of the New York Academy of Medicine (1885-9). In 1900 his 70th birthday was made the occasion of a public demonstration in his honor. Author: "Dentition and its Derangements"; "Infant Hygiene"; "Diphtheria"; "Therapeutics of Infancy and Childhood"; "Infant Diet".

Jacobi, Mary Putnam, American physician: b. London, England, 31 Aug. 1842. She was graduated from the New York College of Pharmacy in 1862, from the Woman's Medical College of Philadelphia in 1864, and from the Ecole de Médecine of Paris in 1871. She then entered practice in New York, in 1881 was appointed clinical professor of the diseases of children in the New York Post-Graduate Medical School, where she lectured for three years. In 1874 she established an association for the promotion of the medical education of women, and became its president. In 1873 she was married to Abraham Jacobi (q.v.). She became a member of the American Medical Association, and published several works, including: "The Value of Life" (1879); "Cold Pack and Anæmia" (1880); "The Prophylaxis of Insanity" (1881); "Common Sense Applied to Woman's Suffrage" (1894).

Jacobins, jāk'ō-bīnz, the most famous of the clubs of the first French Revolution. When

the States-General assembled at Versailles in 1789, it was formed and called the Club Bréton. On the removal of the court and national assembly to Paris it acquired importance and rapidly increased. It adopted the name of Société des Amis de la Constitution, but as it met in a hall of the former Jacobin convent in Paris, it was called the Jacobin Club. It gradually became the controlling power of the Revolution, and spread its influence over France, 1,200 branch societies being established before 1791, and obeying orders from the headquarters in Paris. The Jacobins were foremost in the insurrectionary movements of 20 June and 10 Aug. 1792; they originated the *commune de Paris*, and changed their former name to Les Amis de la Liberté et de l'Égalité. For a while they ruled supreme, and the Convention itself was but their tool. Robespierre was their most influential member; they ruled through him during the Reign of Terror, and were overthrown after his downfall in 1794. In that year the Convention forbade the affiliation of societies; the Jacobin Club was suspended and its hall was closed. The term Jacobin is now often used to designate anyone holding extreme views in politics.

Jac'obite Christians, a subdivision of the sect of the Monophysites (q.v.) comprising those who dwelt in Syria, Mesopotamia, and Babylonia, organized by a certain Jacobus Baradæus, in the reign of Justinian, somewhat later than the middle of the 6th century. Jacobus had been a monk whose poverty-stricken asceticism gained for him the title of Jacobus Baradai (Ragged James). He had been appointed bishop of Edessa in 541, and from that year to 578 he traveled round gathering the members of his heretical sect, until they formed a compactly ordered body which has survived to the present time. They now number about 80,000, and are governed by two so-called Patriarchs, one of Antioch, the other of Jerusalem.

Jac'obites, a party in Great Britain (so styled from Lat. *Jacobus*, James), who after the revolution in 1688 continued to be the adherents of the dethroned King James II. and his posterity. In Ireland they were soon put down by conquest. In England the revolution was accomplished with the apparent consent of all parties; but in a year or two the Jacobite party gained considerable influence, and continued to disturb the government of William throughout his reign. After the accession of Anne and the death of James their efforts slackened for a time; but toward the close of her reign they revived. Bolingbroke and Oxford, with others of the Tory ministers of Anne, were in treaty with the son of James II., and either really or pretendedly negotiated for a restoration. On the arrival of George I. in 1714 a rebellion broke out in Scotland, supported by a more insignificant rising in the north of England. The failure of both these movements damped the enthusiasm of the English Jacobites, but in Scotland the party maintained its influence until the unsuccessful rebellion of 1745 put an end to its political importance, though some ultra-Jacobites did not think themselves justified in transferring their allegiance to the house of Brunswick till the death of Cardinal York in 1807. The hopes and wishes of the

JACOBS — JADE

Scottish Jacobites found expression in many beautiful songs, which form an interesting feature of the national literature.

Jacobs, Henry Eyster, American Lutheran clergyman and theologian: b. Gettysburg, Pa., 10 Nov. 1844. He was graduated from Pennsylvania College (Gettysburg) in 1862, from the Lutheran Theological Seminary at Gettysburg in 1865, was professor of Latin and history in Pennsylvania College in 1870-80, of ancient languages in 1880-1, and of Greek in 1881-3. In 1883 he became professor of systematic theology in the Lutheran Theological Seminary, and in 1894 dean of the faculty of that institution. His publications include: 'The Lutheran Movement in England' (1891); a 'History of the Lutheran Church in America' (1893); 'Elements of Religion' (1894); a 'Life of Martin Luther' (1898); and 'The German Emigration to America 1700-40' (1899).

Jacobs, Joseph, Anglo-American author and journalist: b. Sydney, New South Wales, 29 Aug. 1854. He was graduated from St. John's College, Cambridge, was at various times editor of 'Folk Lore,' the 'Literary Year-Book,' and the 'Jewish Year-Book,' was elected president of the Jewish Historical Society, and became literary editor of the 'Jewish Encyclopaedia.' In 1896 he lectured in the United States. His publications include, beside translations and editions of English classics: 'Celtic Fairy Tales' (1891); 'Indian Fairy Tales' (1892); 'The Jews of Angevin England' (1893); 'Studies in Biblical Archaeology' (1894); 'Literary Studies' (1895); and 'Jewish Ideals' (1896).

Jacobus, Melancthon Williams, American Presbyterian clergyman and educator: b. Allegheny, Pa., 15 Dec. 1855. He was graduated from Princeton in 1877, from the Princeton Theological Seminary in 1881, and after study at Göttingen and Berlin (1881-4), was pastor of the Presbyterian Church at Oxford, Pa., in 1884-91. In 1891 became professor of New Testament exegesis and criticism in the Hartford (Conn.) Theological Seminary. His Stone lectures at the Princeton Theological Seminary (1897-8) appeared as 'A Problem in New Testament Criticism' (1900).

Jacoby, Harold, American astronomer: b. New York 4 March 1865. On his graduation from Columbia University in 1885, he determined to apply himself to astronomical research, a subject in which he had always evinced interest, and he was appointed assistant astronomer United States eclipse expedition to West Africa (1889-90). He has been professor of astronomy at Columbia since 1894 and is an active member of the leading astronomical and scientific societies at home and abroad. He has written numerous technical monographs in astronomical photography, stellar parallax and star clusters which have been published by French, English and Russian societies. He has also been a frequent contributor to the periodical press on popular astronomy.

Jacotot, Jean Joseph, zhōn zhō-zéf zhā-kō-tō, French educator: b. Dijon 4 March 1770; d. Paris 30 July 1840. He was successively soldier, secretary to the minister of war, and deputy-director of the Polytechnic School,

where he was also professor of mathematics. He went to Brussels in 1815, in 1818 was appointed lecturer on the French language in the University of Louvain, and in 1827 director of the Military Normal School. The fundamental principle upon which his system of education rests is that every person is able to educate himself, provided he is once started in the right way. Knowledge should first be acquired through instinctive experience, or by the memory. For example, in imparting a knowledge of a language, Jacotot began by making the pupil commit to memory a single passage; he then encouraged him to study for himself, first the separate words, then the letters, then the grammar, and lastly the full meaning and import. His steps were learn, repeat, reflect, and verify. He expounded his views in 'Enseignement Universel' (1822). Consult: 'Life,' by A. Guillard (1860); Quick, 'Educational Reformers' (1868); Payne, 'Lectures on Education' (1892).

Jacquard, Joseph Marie, zhō-zéf mā-rē zhā-kár, French inventor: b. Lyons 7 July 1752; d. Oullins, near Lyons, 7 Aug. 1834. His parents were silk weavers, and he learned the same trade. After a long period of hardship, during which he shared in some of the campaigns of the Revolution, he made his name famous by the invention of his new loom, which was publicly exhibited in 1801. He endeavored to introduce it into general use in Lyons, but was mobbed, and all but lost his life. Ultimately, however, his invention was bought by the French government, and he was able to spend the latter part of his life in comfortable independence. The subsequent prosperity of Lyons is largely attributable to his invention, and a more enlightened generation erected a statue to him in 1840 on the very spot where his loom was publicly destroyed. See LOOM.

Jacquard Machine. See DAMASK MANUFACTURE.

Jacquerie, zhák-è-rē, the name given to the rising of the French peasantry in the 14th century after the battle of Poitiers. They committed great devastations and outrages—burning castles, murdering men and violating women—particularly in the northeast of France. They were at length quelled by the Captal de Buch and Gaston Phébus, count of Foix, who slaughtered 7,000 of them near Meaux. The term *Jacquerie* is derived from *Jacques Bonhomme*, a familiar epithet for a peasant.

Jade, a remarkably tough, compact, ornamental stone, of green to white color and vitreous lustre, used by the prehistoric peoples of Switzerland, Mexico, Alaska, and other countries for axes, utensils and carvings. It is still highly prized in the East, especially in China and New Zealand. Jade is a general term including two distinct minerals, jadeite and the more common nephrite. Jadeite belongs to the pyroxene group and chemically is a soda-silicate, easily fusible (at 2.5) and having a specific gravity of 3.3 to 3.35. Nephrite is a variety of amphibole identical with tremolite when of white color, or with actinolite when green, fusing much less easily (at 4) and with specific gravity of 2.95 to 3.0. Much information as to jade and implements made from it may be found

JADWIN — JAGUAR

in the publications of the Smithsonian Institution, especially a paper by S. Blondel, 'A Historical, Archæological and Literary Study of Jade,' in the annual report for 1876.

Jad'win, Edgar, American military engineer: b. Honesdale, Pa., 1865. He studied at Lafayette College, was graduated from West Point in 1890, was an assistant in government engineering in 1890-1 and again from 1893, in the Spanish-American War was successively major and lieutenant-colonel of the 3d United States volunteer engineers, and for a time commanded a battalion of this regiment in the sanitation of Matanzas, Cuba. Promoted captain in the corps of engineers, U. S. A. (1900), he was appointed (1902) to direct all Pacific coast fortification and river and harbor work south of San Francisco.

Jæger, yā'gēr. See GULL; SKUA.

Jaffa, jāffā or yāf'fā (ancient JOPPA; Ar. *Yafa*; Heb. *Yapho*, beauty), Asiatic Turkey, in the western part of Palestine on the Mediterranean Sea; about 35 miles from Jerusalem. Jaffa is an old Phœnician town mentioned in several places in the Bible. It was the port of entry for Jerusalem and for several of the interior cities of Palestine. Here the cedars from Lebanon were landed and then carried overland for the building of the Temple in Jerusalem. The house where Simon the tanner lived, and where Saint Peter lodged, is still pointed out. In 1187 it was taken by Saladin, in 1191 by Richard I. In 1799 it was captured by Napoleon, who here put to death 1,200 Turkish prisoners. The narrow entrance to the harbor is extremely dangerous. The city is built on a high rocky coast, and presents today the same irregular arrangement of streets, and unattractive looking houses that it may have had hundreds of years ago. The remains of Roman fortifications and dwellings are in the vicinity. The old road to Jerusalem is extremely interesting; but a railroad, built in 1892, connects the city with Jerusalem. The chief exports are oranges (said to be the finest in the world), other fruits, soap, sesame, wine, oil, raw silk, and nuts. The chief imports are sugar, rice, lumber, cotton goods, petroleum, tobacco, and silk goods. The city contains several mosques, a Franciscan monastery, and a mission school. Some attempts have been made to establish colonies of Jews on land near Jaffa. Pop. (1903) estimated, 30,000.

Jagannath, or Juggernaut (Sanskrit, *Jagan-nâtha*, lord of the world, one of the names of Vishnu), called by the natives Puri, a town and celebrated temple of Hindustan, in the presidency of Bengal, province of Orissa, on the Bay of Bengal, 48 miles south of Kattack. The town derives all its importance from the temple. This, the most celebrated shrine in Hindustan, was completed in the 12th century, at an enormous expense. The main street, at the extremity of which the temple stands, consists entirely of religious structures built of stone. The gardens here produce the finest fruits in the province. The temple stands near the shore, in a waste, sandy tract, and appears like a shapeless mass of stone. The idol is a carved block of wood, with a hideous face, painted black, and a distended blood-red mouth, and is magnificently

dressed. On festival days the throne of the image is placed on a high tower moving on wheels. Long ropes are attached to the tower, by which the people draw it along. The belief that devotees used to cast themselves headlong in front of this car to be crushed to death probably grew out of the accidental fatalities sometimes occurring. Every year pilgrims flock in crowds to the temple.

Jagersfontein (yā'gérz-fōn-tīn) **Excelsior, The**, a name given the largest known diamond; found in the mine of the Jagersfontein Company, Orange Free State, South Africa, in 1893; weight, 971 carats; color, blue white.

Jag'ger, Thomas Augustus, American Protestant Episcopal bishop: b. New York 2 June 1839. He was graduated from the General Theological Seminary, New York, and ordained deacon in the Protestant Episcopal Church 1860. While serving as rector of Holy Trinity parish, Philadelphia, Pa., he was elected to the newly formed diocese of Southern Ohio, and consecrated May 1875. He is the author of 'The Men of the Ages'; 'The Ministry of Phillips Brooks'; 'The Personality of Truth,' the Bohlen lectures for 1900.

Jaggery, a coarse brown sugar made in the East Indies by the evaporation of the juice of several species of palms, chemically the same as cane-sugar. The sap which yields jaggery becomes by fermentation palm-wine, and from it arrack (q.v.) is distilled. See PALM.

Jaguar, jäg'u-är or jäg'wär, a great American spotted cat (*Felis onca*), once numerous as far north and east as Arkansas, but since the early part of the 19th century rare even in Mexico. It resembles the leopard, but is more robust (exceeding the cougar in weight), has a rounder head, relatively shorter legs and a shorter, thicker tail. The tawny yellow hide is spotted with black, the spots larger than those of the leopard, and inclined to form broken rings with a spot in the centre. Jaguars abound in the tropical forests, especially along the great rivers, where they find most prey. They subsist largely on capybaras, agoutis, etc., but frequently pounce upon deer when they come down to drink. They seem to be more arboreal than most large cats, and a favorite method of obtaining their food is to lie along a tree-limb in some favorable spot and leap down upon the victim. But jaguars also abound in the treeless morasses of the Gran Chaco, and even on the dry uplands of Paraguay and Argentina, where their food and habits are entirely different from those who dwell in the forests. In view of the great extent of country and variety of circumstances in which this animal occurs, formal statements as to its habits are rarely more than locally true; and much error and superstition encumbers popular accounts. In general the jaguar has the manners and disposition of other great cats, changing with environment, season and circumstances. It submits grudgingly to captivity, and gives the same reluctant submission to the training of the circus as is exhibited by other great cats. In some regions it is greatly feared by the people, while in other places it is regarded as little to be feared. Its greatest peculiarity, perhaps, is the tendency to terrific roars and cries, more loud and continuous than those of cougars or leop-

JAGUARONDI—JAMAICA

ards. Consult the works of South American travelers and naturalists, especially Humboldt, Azara, Walerton, Wallace, Bates, and W. H. Hudson. Their accounts are well summarized by Porter in 'Wild Beasts' (New York 1894).

Jaguarondi, jäg-wä-rön'di, or **Yaguarondi**, a slender, long-tailed, unspotted, blackish-gray wildcat (*Felis jaguarondi*) of tropical America. It is not common, and is little known. It measures about 30 inches from snout to tail, and the tail is 25 inches long; and the sides of its nose are curiously pinched in.

Jains, jinz, or **Jainas**, ji'näz, a Hindu religious sect, which in union with the Buddhists opposed Brahmanism. They are numerous in the great cities of western and northwestern India, as well as in the Dravidic states of the South. The name signifies a follower of Jina ("conqueror of the world"), one of the denominations of their apotheosized saints. They have many fine temples built in different parts of the Deccan, as well as elsewhere. The Jains deny the divine origin and infallible authority of the Vedas; they reverence certain holy mortals, now termed Tirthankara or saints, and they manifest extreme and even ludicrous tenderness for animal life. They positively affirm that the world exists from all eternity, not being created by God or any other being, and that it will exist forever. This world is divided into three parts—the upper, the middle, and the lower worlds. The Jains believe that not to kill any sentient being is the highest virtue; and lying, covetousness, theft, are strongly condemned. Not to eat at night, and to drink water strained (for fear of its containing any insect), not to drink arrack, are important injunctions. Various fruits and vegetables they will not eat even under the pressure of starvation, and any kind of flesh meat they will not touch with the hand. They believe in a sort of nirvâna (like the Buddhists). Those who attain to this nirvâna, this extinction of action, this final liberation, do not return to a worldly state, and there is no interruption to their bliss; they have perfect vision and knowledge, and do not depend upon works. The Jains are split up into two principal divisions, Digambaras and Svetâmbaras; the points of difference between them are said to comprehend a list of 700 topics, 84 of which are considered of paramount importance. The Digambara (sky-clad, naked) now wears colored garments, confining the disuse of clothes to meal hours; the Svetâmbara wears, as the name signifies, white garments. Both the parties have the same sacred books, which they style "angas," but no sacerdotal caste.

Jal'ap (so called from Jalapa, or Xalapa, Mex., whence it is imported), the tuberous roots of several plants of the order *Convolvulaceæ*, that of *Ipomaea purga* being the most important. This is a twining herbaceous plant with cordate leaves and deep pink flowers, growing naturally on the eastern declivities of the Mexican Andes, at from 5,000 to 8,000 feet. The jalap of commerce consists of irregular ovoid dark-brown roots, varying from the size of an egg to that of a hazel-nut. The drug is one of the most common purgatives, but is apt to produce griping and nausea.

Jalapa, hä-lä'pä, or **Xalapa** ("a place of water and sand"), Mexico, city, capital of the

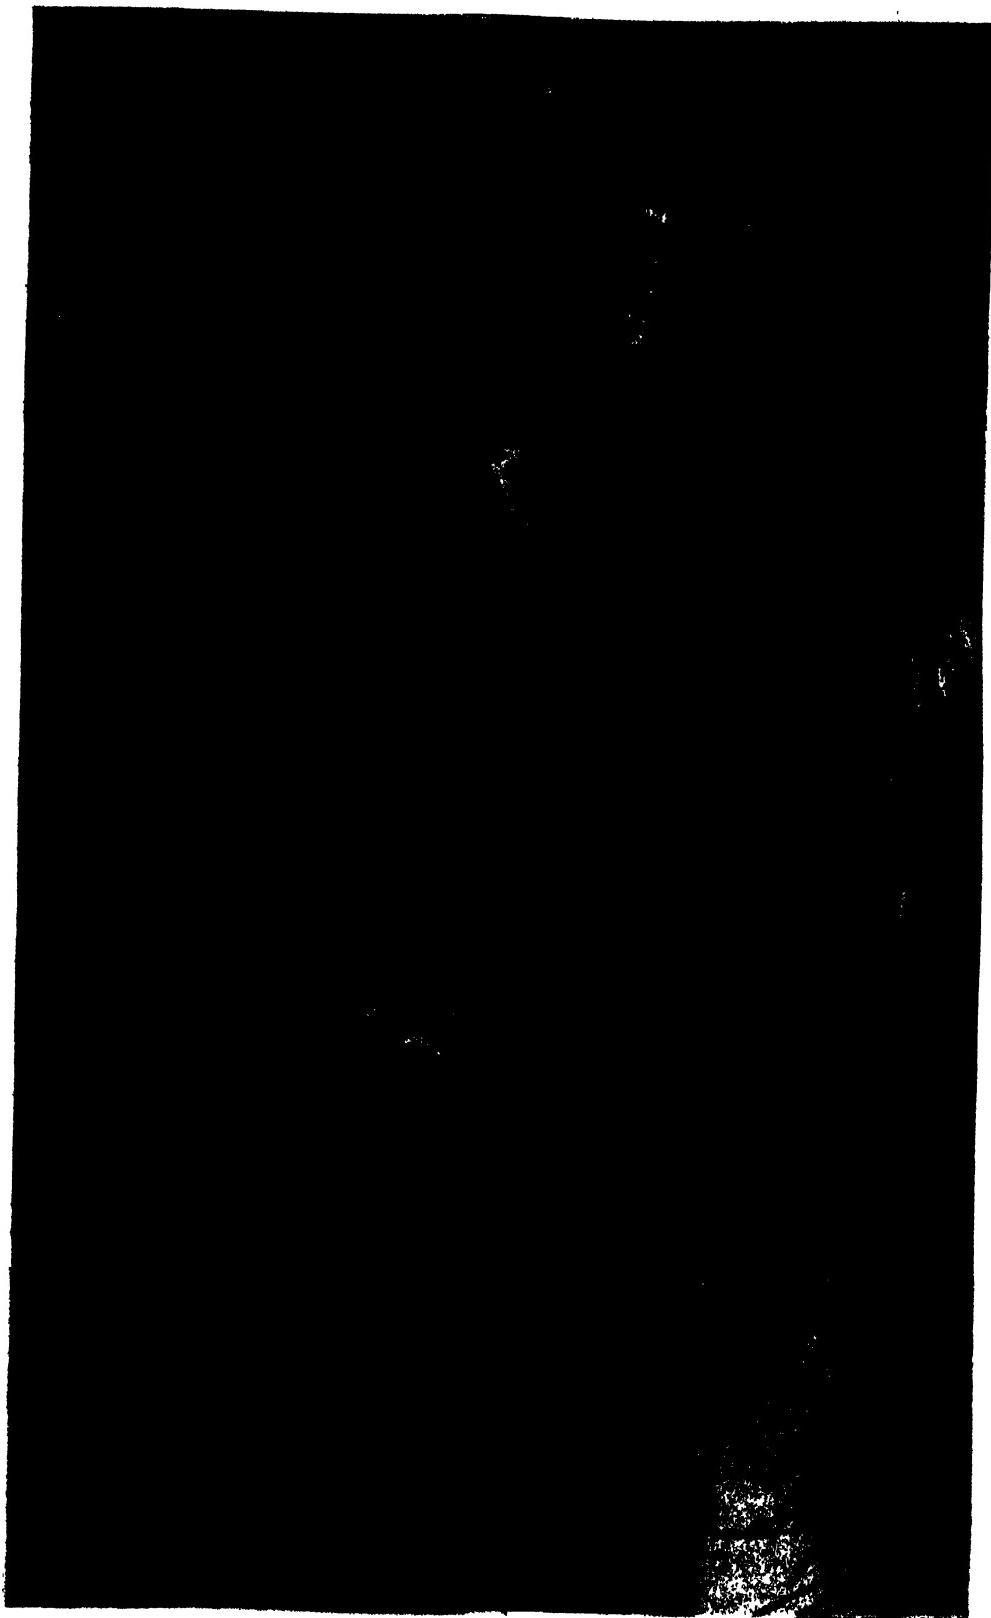

state of Vera Cruz; on the railroad which extends from the city of Vera Cruz across the state of Vera Cruz and Puebla; about 50 miles northwest of Vera Cruz. Jalapa is situated about 4,340 feet above the sea, at the base of the basaltic mountain, Cofre de Perote, which rises about 14,300 feet. Before the advent of railroads, the route from Vera Cruz to Mexico City was through Jalapa, which was then of considerable importance. It is a favorite mountain resort for the inhabitants along the coast and in the valleys. The irregularity of the streets, the gardens which surrounded the city, the well-built houses, the parks, and promenades, all make the place most attractive. It was once the capital of the state. It is one of the oldest cities on the continent; one of its churches is said to have been built by Cortes, who found here an Indian town. The Franciscan convent was built in 1556. The great annual fair held here between the years 1720-77 made Jalapa a place of note. People came from far and near to see and purchase goods brought from Europe, mostly from Cadiz. In the city there are three hospitals, a number of good schools, and several fine church buildings. Pop. (1903) 20,500.

Jalisco, hä-lës'kō, Mexico, a state bounded on the west by the Pacific Ocean, and on the north, east, and south by the states of Durango, Zacatecas, Aguascalientes, San Luis, Potosí, Guanajuato, Quenetaro, Michoacan, Colima, and the territory of Tepic. The Sierra Madre range in the eastern portion of the state includes the active volcano Colima (about 14,238 feet) and other high mountains. The largest river is the Santiago, or Lerma, which forms the cascades of Juanacatlan in the vicinity of the city of Guadalajara. At that point the river is 520 feet wide, and falls 65 feet. A large electric plant utilizes the force generated by these falls, supplying electric power to a number of factories. Lake Chapala, the source of the Santiago, is the largest body of water in the republic. The total mineral production of the state is somewhat more than \$2,250,000 Mexican silver. There are numerous silver, gold, copper, iron, lead, and cinnabar mines. The high table-lands of the eastern regions have a temperate or cold climate, and produce cereals; in the valleys and on the hot lowlands of the coast sugar-cane, cotton, vanilla, tobacco, oranges, and coffee are cultivated. The maguey plant is one of the chief products of the district of Tequila. The annual output of sugar is 11,000 tons of the raw, and 15,000 tons refined. The capital of the state, Guadalajara (q.v.), has become in recent years one of the chief manufacturing centres in Mexico, producing large quantities of *manta*, or unbleached cotton, and leather goods. More than \$300,000 Mexican silver is appropriated annually for the maintenance of schools, which are attended by 31,725 pupils. Private and church schools have an attendance of 14,106. The population of the state in 1900 was 1,137,311.

Jalla'o, a West Indian market-name for the margeate-fish (q.v.).

Jamaica, ja-mä'ka, the largest of the British West India Islands. It occupies the central position in the Antillean region, being nearly equidistant from Florida and the northern point of South America; from the mouths of the Orinoco and Galveston; from the head of the

SOUTH AMERICAN JAGUAR AND TAPIR.

JAMAICA

Gulf of Honduras, on the west, and St. Thomas, on the east. Its greatest length is 144 miles; greatest breadth, 49 miles; area, 4,200 to 4,218 square miles. The eastern part of the island has, as its most commanding feature, the Blue Mountain range (highest peak 7,360 feet). The centre and west, an elevated plateau of later geologic formation, show the characteristic Antillean limestone, and, more perfectly here than elsewhere in the West Indies, the extraordinary results of exposure of that soluble material to the tropical rainfall. This upland plain, by the action of the elements, has been carved into hills, basins, called "cockpits," 500 feet or more in depth, and much larger and deeper valleys, in which the plantations are situated, and from which the numerous streams often find their way to the sea by underground passages. One of these depressions, the Clarendon Valley (drained through a cañon), is 25 miles wide and 50 miles long; another, St.-Thomas-in-the-Vale, is circular in form, with a diameter of about 10 miles. Throughout the western half of the island such valleys occur, some with, others without, apparent drainage outlets. Coastal plains are most extensive on the south side, where the largest, the plain of Liguanea, has an area of 200 square miles. There are no navigable rivers, but a great number of small streams, pools, and thermal springs. In the limestone region there are many caverns, interesting on account of their size, beauty, or the relics of the old Indian population which they contain. The mean temperature at the coast is very little more than 78° F.; that of the larger part of the habitable regions (1,000 to 3,000 feet above sea-level) is about 73° F.; and at the altitude of 5,500 feet it is 60° F. The maximum for a period of 10 years at Kingston, on the south coast, averaged 87.8° F., and the minimum 70.7° F. On the plateau the annual variation is scarcely 9°; for example, at St. Elizabeth the maximum is 75° F. and the minimum 67° F. As a whole, the island has a pleasant climate. The average rainfall is 66 inches, the extremes being 100 inches on the high mountains and 44 inches at Kingston. The death-rate is 20.9 in 1,000; but this favorable showing, as compared with the other islands of the Antilles, is due much less to natural advantages than to the strict enforcement of local sanitary and quarantine regulations. The total number of inhabitants in 1903 is estimated at about 780,000. The census of 1891 showed 639,491, five sixths of the entire population being blacks or colored people; the whites numbering 14,692, and East Indian coolies 10,116. The birth-rate is little less than twice the death-rate. The Jamaican negroes are fairly good laborers when well fed; the menial work of the island is performed by them, and they are regarded as cheerful, honest, and respectful servants. They have no share whatever in the government.

Fauna, Flora, and Agriculture.—Jamaica has no native mammals. There are many species of lizards, including the large iguana, a few harmless snakes, and the slightly poisonous centipede and scorpion; in the lowlands mosquitoes, ants, and sand-flies are common; butterflies, fireflies, and beetles, parrots, pigeons, water-fowls, and 20 different kinds of song-birds are enumerated. Edible marine fish are seldom caught near the island, but the streams contain a few fresh-water species. The flora is distinguished

from that of the other Antillean regions by the total absence of the royal palm, and by the abundance of pimentos, or allspice-trees, which are found nowhere else. Common trees are the ceiba, mango, wild orange, cocoa-palm, plantain, fustic, logwood, and cedar. Begonias, orchids, ferns, and grasses abound, except on the southern coast, which has a flora of the arid type, including the cactus, thorny acacias, etc. There are 739,256 acres under cultivation (tillage 200,168, pasturage 413,152, etc.). Of this total, 83,549 acres are devoted to pimento (allspice), but chiefly as a by-product on lands also used for stock-raising. Since the abolition of slavery the production of sugar has fallen off very greatly. In 1805 Jamaica exported 151,000 hogsheads of sugar, and 5,000,000 gallons of rum; in 1897 the cultivation of sugar-cane constituted only 19 per cent of the whole agricultural industry; in 1902 only 27,342 acres were under this crop. Other products have gradually taken its place, as shown in the following statement of areas devoted to them: Ground provisions, 91,733 acres; coffee, 31,265 acres; bananas, 32,842 acres; cocoanuts, 13,244 acres; etc. Since the great frosts in Florida (1895-6) the exportation of oranges from Jamaica has been carried on profitably; since 1886 tobacco has been grown and cigars for exportation made on a large scale. Coffee from the Blue Mountain estates is of fine quality. The cultivation of cocoa has increased in recent years; ginger grows most readily in the rich soils on the mountains; and among the other exports may be mentioned annatto, lime-juice, tamarinds, nutmegs, a number of dye-woods, cabinet-woods, etc. Special instruction in agriculture is given at the schools, and agricultural and horticultural interests are encouraged by the government and active private associations.

Commerce, Railways, Roads, etc.—The United States has the most important trade relations with Jamaica, furnishing a large part of the staple food supplies, and affording the best market for the island's fruit and sugar. Thus, in 1895-6, the total exports were valued at \$8,900,000, the United States taking 57 per cent, and Great Britain 27.6 per cent. Imports in the same year amounted to \$13,722,500, Great Britain, Canada, and other British possessions furnishing about 55.6 per cent, and the United States 41.8 per cent. There are about 185 miles of railway, 683 of telegraph, and 154 of telephone. In the year 1901-2 the number of letters and postal-cards transmitted by the post-office was 5,424,814. The system of public highways (3,600 miles), extending into all parts of the island, is admirable: the roads are thoroughly well built and graded, have substantial bridges, and are kept in good repair. The principal line of steamships is the Royal Mail, with fortnightly sailings between England and the Caribbean ports. The Atlas Line and the Boston Fruit Company's steamers maintain communication with New York, Boston, Philadelphia, and Baltimore. A steamer from Kingston circumnavigates the island once a week.

Government, Education, and Religion.—The executive authority is vested in a governor, appointed by the king. He is assisted by a secretary, attorney-general, director of public works, collector-general, and the commanding officer of the military forces. The legislative council consists of 29 members, with the governor as

JAMAICA—JAMAICA BAY

president; of the whole number 14 are elected (term 5 years), 10 nominated, and 5 are the administrative officers mentioned above. Admittance to the lower grades of the civil service is gained through competitive examinations. The government medical service has in charge 18 public hospitals. The police system includes more than 100 stations in different parts of the island; a force of more than 1,500 men (769 district constables); several prisons, reformatories, and industrial schools. In 1902 the strength of the regular forces stationed in Jamaica was 1,866 officers and men; militia, 763. Fortifications and batteries are at Port Royal, Rocky Point, Salt Pond's Hill, Rock Fort, Fort Augusta, Fort Clarence, and Apostles' Battery. Ships of the royal navy on the North American and West India station are 13 in number (see also below in connection with Kingston). The judicial department includes a high court of justice (9 members), circuit courts, and a magistrate in each parish. Public revenue and expenditure in recent years, each about \$3,000,000; the public debt in 1897 was given as \$7,581,000. Government schools in 1902 numbered 728, with 84,779 pupils. There are four government training colleges for teachers; several endowed secondary, industrial, and high schools; a public lyceum and museum, with a valuable library, etc. Local examinations are held on the island by the University of Cambridge. In 1870 the Church of England was disestablished and disendowed on the island; in 1902 churches and chapels were: Church of England, 219; Baptist, 189; Methodist, 128; Presbyterian, 73; United Methodist Free Church, 43; Roman Catholic, 28; Moravian, 27; Congregational, 26; Christian Church, 20; and Church of Scotland, 10.

Dependencies.—The Cayman Islands, Turks, and Caicos Islands, and the Morant and Pedro Cays are attached to Jamaica for administrative purposes. Of these, the first group lies in the Caribbean Sea, 180 miles northwest of Jamaica, and comprises Grand Cayman, 17 miles long, 4 to 7 broad; Little Cayman, 9 miles long and about 1 mile broad; and Cayman Brae, 10 miles long and 1 mile broad. The government is administered by a commissioner, and magistrates are appointed by the governor of Jamaica. The population will be referred to under *History*. The second group, Turks and Caicos Islands, situated nearly 500 miles northeast of Jamaica, geographically belongs to the Bahamas; but the governor of Jamaica exercises a supervising power over the local authorities (a commissioner and legislative board of 5 members). Area, 165 square miles; population, 5,350; capital, Grand Turk; products, salt, sponges, pink pearl, etc. The Morant Cays and Pedro Cays are situated, respectively, about 33 miles southeast, and about 45 miles southwest, of Jamaica.

Chief Towns.—Kingston, the capital, has 46,542 inhabitants, a good water-supply and system of sewerage, well-lighted streets, large shops, a street-railway, etc. The town is, however, unattractive; residences of the officials and wealthy merchants are built in the suburbs. Public institutions are the museum, library, colonial offices, schools, churches, almshouse, penitentiary, asylum, and Victoria Market. Four miles away is the important naval station of Port Royal, headquarters for the British West India naval forces, and a strongly fortified

place. Spanish Town, population 5,019, at one time the capital, is situated 15 miles west of Kingston. Port Antonio, on the northeast side of the island; Montego Bay, population 4,803; Savanna-la-Mar, Falmouth, Lucea, St. Ann's Bay, Buff Bay, Port Morant, Black River, etc., are distributed among the three counties of Surrey, Middlesex, and Cornwall.

History.—The native word from which we have the name Jamaica signifies "island of fountains." Names recalling the old Spanish occupation of the island are Montego (Spanish Manteca), Bog Walk (Spanish Boca del Agua), Wag Water (Spanish Agua Alta), and others. As a Spanish colony (1509–1665) Jamaica was backward and of little consequence; the total population in the year last mentioned, when an English fleet captured it, was only 3,000. One half of that number took refuge in Cuba. The settlers who arrived subsequently were peasants from Scotland, Ireland, and England, English subjects from the other West Indian islands, and Jewish traders from Minorca. Negroes were brought from Africa in great numbers; the old town of Port Royal being chosen as a convenient point from which to reship slaves to the other islands and the mainland. That town, once a place of great wealth and importance, was ruined by repeated calamities. "On 7 June 1692 happened that earthquake which swallowed up great part of Port Royal," says Edwards, who explains that the town "was chiefly built on a bank of sand, adhering to a rock in the sea, and a very slight concussion, aided by the weight of the buildings, would probably have accomplished its destruction." Hurricanes in 1712 and 1722, and a conflagration 13 July 1815, completed the work of obliteration. Toward the close of the 18th century the island was occupied by large plantations, and was exceedingly productive. Before that time 60,000 slaves had been landed at Port Royal. The freeing of the negroes (see EMANCIPATION) resulted in the abandonment of the island by many landlords. The effort to regain the lost prosperity through diversified agriculture has already been mentioned. In August 1903 a hurricane inflicted great injury at several points in Jamaica, and destroyed life and property on the Cayman Islands. The population of the latter was 4,322 according to the census of 1891, and the productions tropical fruits.

Consult: Hill, 'Cuba and Porto Rico, with the other Islands of the West Indies'; and Edwards, 'History of the British West Indies.'

MARRION WILCOX,
Authority on Spanish America.

Jamaica, a part of the borough of Queens in the city of New York. Prior to 1 Jan. 1898 Jamaica was the county-seat of Queens County on Long Island, but that portion of Queens County in which Jamaica is situated has been incorporated in the city of New York (Greater New York). The town was settled as early as 1656. Several houses built before the Revolutionary War are in a good state of preservation. In the vicinity there are a large number of market gardens. One of the New York State normal schools is situated in Jamaica.

Jamaica Bay, an inlet of the Atlantic Ocean which indents the southeast shore of Long Island. It is nearly circular in shape; the Rockaway Beach extends across the side toward the ocean and makes of the bay a land-locked body

JAMES

of water. A number of islands are in the middle and at the entrance. The whole of the bay, except an inlet, Head Bay on the east shore, is within the limits of New York city; Coney Island is near the entrance to the bay.

James, Saint, called the "Greater," the son of Zebedee. He was called to be an apostle, together with his brother Saint John, as they were mending their nets with their father, who was a fisherman. They then followed Christ, were witnesses with Saint Peter of the transfiguration, and accompanied our Lord in the garden of Gethsemane. In the lists of the apostles given in the synoptic Gospels and in the Acts the names of Peter, Andrew, James, and John stand first; and it is plain that these four were at the head of the 12 throughout. After the ascension Saint James persevered in prayer with the other apostles and the women and the Lord's brethren. Nothing further is certainly known of him till the passover of 44, when, being in Jerusalem, the Jews stirred up Herod Agrippa I. against him, who put him to a cruel death. Thus Saint James was the first of the apostles who suffered martyrdom. There is a legend that he went to Spain, and that his bones lent miraculous aid to the Spaniards against the Saracens.

James, Saint, called the "Less," an apostle, the brother or cousin of Jesus. He is called in Scripture the "Just," and is probably the apostle described in Matt. x. 3 and elsewhere as the son of Alpheus. He was the head of the church in Jerusalem when the Scribes and Pharisees threw him down from the gable of the temple, and a fuller dashed out his brains with a club, about the year 62. This is the account of his death given by Hegesippus, a Christian of Jewish origin, who lived in the middle of the 2d century, and it differs somewhat from the narrative of Josephus. Some critics maintain that James, the son of Alpheus, was one person, and James, the brother of Jesus, another. Whether James was the author of the epistle which bears his name is considered doubtful.

James I., king of England, and VI. of Scotland, the only child of Mary, Queen of Scots, by her cousin Henry Stuart, Lord Darnley: b. Edinburgh Castle 19 June 1566: d. palace of Theobalds, Hertfordshire, 27 March 1625. In 1567 he was solemnly crowned at Stirling, and from that time all public acts ran in his name. His childhood was passed in civil wars, under the regencies of Murray, Mar, and Morton, during which time he resided in Stirling Castle, under the tuition of the celebrated Buchanan. From the first he seems to have imbibed those exalted notions of the royal authority and divine right which proved so injurious to his posterity. But James soon found it advisable to ally himself with Queen Elizabeth and accept a pension from her. When, however, it became apparent that the life of his mother was in danger from the sentence of an English judicature, James sent representatives to England to intercede with Elizabeth; but his whole procedure in the matter shows a singular callousness. As a matter of form he ordered the clergy to pray for his mother, but when the news of Mary's execution arrived James was not much moved, though he attempted to make a show of indignation by

condemning one of the commissioners to death, a sentence which, however, he commuted to banishment. On 23 Nov. 1589 James married Anne, daughter of Frederick II., king of Denmark. On his return home, after passing the winter in festivities at Copenhagen, he was in some danger from the unruliness of the nobles; and for several succeeding years of his reign the history of Scotland displays much turbulence and party contest. In 1603 James succeeded to the crown of England, on the death of Elizabeth, and proceeded amidst the acclamations of his new subjects to London. One of his first acts was to bestow a profusion of honors and titles on the inhabitants of both countries. At a conference held at Hampton Court between the divines of the Established Church and the Puritans James exhibited the ill-will he bore to popular schemes of church government. The meeting of Parliament also enabled him to assert those principles of absolute power in the crown which he could never practically maintain, but the theoretical claim of which provided the increasing spirit of freedom in the House of Commons with constant matter of alarm and contention. Although James had behaved with great lenity to the Catholics in Scotland, those in England were so disappointed in their expectations of favor, that the famous gunpowder plot was concerted in 1605, the object of which was to blow up the king and Parliament. (See GUNPOWDER PLOT, THE) In 1612 he lost his eldest son Henry, a prince of great promise, then 19; and in the following year the eventful marriage of his daughter Elizabeth with the elector palatine took place. No circumstance in the reign of James was more unpopular than his treatment of the celebrated Sir Walter Raleigh (q.v.). James had set his heart on marrying his son Charles to a Spanish princess, but the negotiations failed through the overbearing temper of Buckingham, the royal favorite, who quarreled with the grandees of the Spanish court. The close of the life of James was marked by violent contests with his Parliament. He was also much disquieted by the misfortune of his son-in-law, the elector palatine, who, having been induced to accept the crown of Bohemia, and to head the Protestant interest in Germany, was stripped of all his dominions by the emperor. Urged by national feelings for the Protestant cause, he was at length (10 March 1624) induced to declare war against Spain and the emperor; and troops were sent to Holland to act in conjunction with Prince Maurice. James was not destitute of abilities nor of good intentions, but the former were not those of a ruler, and he was neither beloved at home nor esteemed abroad. He received during his lifetime a great deal of adulation on the score of his literary abilities. Consult: Aikin, "Memoirs of the Court of King James the First" (1822); Burton, "History of Scotland" (1873); Macaulay, "History of England" (1858); S. R. Gardner, "History of England from the Accession of James I. to the Spanish Marriage" (1863-9); ibid., "The First Two Stuarts" (1876).

James II., king of England, second son of Charles I. and of Henrietta of France: b. London 15 Oct. 1633; d. St. Germain, France, 16 Sept. 1701. He was at once declared Duke of York, though only formally raised to that

JAMES

dignity in 1643. At the Restoration in 1660 he took the command of the fleet, as lord high-admiral, and was also made Warden of the Cinque Ports. He had previously married Anne, daughter of Chancellor Hyde, afterward Lord Clarendon (q.v.). In 1671 the Duchess of York died. Before her death she declared herself a convert to the Roman Catholic faith, which had been secretly that of the duke for many years, and was now openly avowed by him. This declaration laid the foundation of the opposition which finally drove him from the throne. A test act being soon after passed, to prevent Roman Catholics from holding public employments, the duke was obliged to resign his command. On 21 Nov. 1671 he married Mary Beatrice of Este, daughter of the Duke of Modena, and in 1677 his eldest daughter, Mary, was united to William, prince of Orange.

On the death of Charles II., 6 Feb. 1685, the duke succeeded, under the title of James II., and from the time of his ascending the throne seems to have acted with a steady determination to render himself absolute, and to restore the Roman Catholic religion. At variance with his Parliament he was under the necessity of accepting a pension from Louis XIV. He sent an agent to Rome to paye the way for a solemn re-admission of England into the bosom of that Church, conduct which encouraged the rebellion of the Duke of Monmouth. The unrelenting temper of James was again exhibited in the executions on this account. The legal proceedings under Jeffreys were brutal in the extreme; and no fewer than 320 persons were hanged on the western circuit alone, which attained an unenviable notoriety as the Bloody Assize. He gradually proceeded to a direct attack on the Established Church, by the formation of an ecclesiastical commission, which cited before it all clergymen who had done anything to displease the court. Apparently to conciliate the Puritans a declaration of indulgence in matters of religion was ordered to be read by the clergy in all the churches of the kingdom, but its real object, however, was to favor the Roman Catholic element. Seven bishops met and drew up a loyal and humble petition against this ordinance, and for this act they were sent to the Tower, on a charge of seditious libel. On 29 June 1688 they were acquitted amid the most enthusiastic rejoicings of the populace. The innovations, in regard both to the religion and government, gradually united opposing interests, and a large body of nobility and gentry concurred in an application to the Prince of Orange, signed by seven of the most prominent and influential political leaders, to occupy the throne. James, who was long kept in ignorance of these transactions, when informed of them by his minister at the Hague, was struck with terror equal to his former infatuation; and, immediately repealing all his obnoxious acts, practised every method to gain popularity. All confidence was, however, destroyed between the king and the people. William arrived with his fleet in Torbay 5 Nov. 1688, and landed his forces, amounting to 14,000 men. Several men of rank went over to William, and the royal army began to desert by entire regiments. Incapable of any vigorous resolution, and finding his overtures of accommodation disregarded, James resolved to quit the country. He repaired to St. Ger-

main, where he was received with great kindness and hospitality by Louis XIV. In the meantime the throne of Great Britain was declared abdicated, and was occupied, with the national and parliamentary consent, by his eldest daughter, Mary, and her husband, William, conjointly; Anne, who had equally with her sister been educated a strict Protestant, being declared next in succession, to the exclusion of her infant brother, known in history as the Pretender, who had been born on 10 June of that year. Assisted by Louis XIV., James was enabled, in March 1689, to make an attempt for the recovery of Ireland. The battle of the Boyne, fought 1 July 1690, compelled him to return to France. All succeeding projects for his restoration proved equally abortive. Consult: Burnet, 'History of the Reign of King James the Second'; Cavelli, 'Les derniers Stuarts à Saint Germain-en-Laye' (1871); Klopp, 'Der Fall des Hauses Stuart' (1875-88).

James I., king of Scotland, of the house of Stuart: b. Dunfermline 1394; d. Perth 21 Feb. 1437. He was the son of Robert III. In 1406, while on his way to France, he was taken by the English and carried to the Tower of London. For the next 18 years he remained a prisoner in England, being confined during part of his captivity in Nottingham Castle, Evesham, and Windsor Castle, where he wrote the 'King's Quhair' and other poems. Robert III. died very shortly after learning of his son's captivity, and James was proclaimed king; but during the remainder of the reign of Henry IV., and the whole of that of Henry V., he was detained in England, with a view to prevent the alliance of Scotland with France. In 1424, under the regency of the Duke of Bedford, he was restored to his kingdom, at which time he was in his 30th year. Previous to his departure he married Jane or Joanna Beaufort, daughter of the Earl of Somerset, a lady of the blood royal of England, who is the fair dame alluded to in his poem 'The King's Quhair.' On his return to Scotland he restored Scotland to some degree of order, but so severe was his treatment of his turbulent nobles that he was at last murdered by their emissaries at Perth in the 13th year of his reign.

James II., king of Scotland, son of James I.: b. 16 Oct. 1430; d. Roxburgh, Scotland, 3 Aug. 1460. During the minority his kingdom was distracted by struggles for power between his tutors Livingston and Crichton and the great house of Douglas. In 1449 he assumed the government and married Mary of Guelderland. He had latterly allied himself with the Douglasses, but being deprived of all real power, he resolved to free himself from their yoke. This he did in 1452 by inducing the Earl of Douglas to come to Stirling Castle, where he stabbed him with his own hand. He then quelled a powerful insurrection headed by the next earl, whose lands were confiscated. In 1460 he infringed a truce with Henry VI. of England by besieging the castle of Roxburgh, and was killed by the bursting of a cannon in the 29th year of his age.

James, III., king of Scotland, son of James II.: b. 10 July 1451; d. 11 June 1488. He was crowned at Kelso on his father's death, but in 1465 came under the influence of Bishop Ken-

JAMES

nedy and the Boyd family, one of the latter espousing the king's sister in 1467. James married Margaret of Denmark in 1469 and dismissed the Boyds from favor only to advance other favorites. Prominent among these was Cochrane, through whom one brother of James was obliged to flee the kingdom, and another was put to death. The nobles seized Cochrane and five others and hanged them. Subsequently a plot was formed to dethrone the king, and though many peers remained loyal to him the royal army was defeated at Sauchie, near Stirling. James escaped from the field, but was murdered during his flight.

James IV., king of Scotland: b. 17 March 1473; d. Flodden 9 Sept. 1513. He was the son of James III. He commanded the nobles who vanquished and killed his father at Sauchieburn, and was crowned at Scone in June 1488. He married Margaret, the daughter of Henry VII. of England, but taking umbrage at the hostile attitude of his brother-in-law, Henry VIII., allied himself with France. He was defeated and slain at the battle of Flodden (q.v.) during an invasion of England.

James V., king of Scotland, son of James IV.: b. Linlithgow, Scotland, 10 April 1512; d. Falkland Palace 14 Dec. 1542. He came to the throne under the regency of his mother in 1513 and assumed the reins of government in 1528. He married Madeleine of France in 1537, and on her death married the daughter of the Duke of Guise, Mary of Lorraine, in 1538. He ruled with much vigor and decision, and on account of his mingling freely with his people was called "the king of the commons." Becoming entangled in war with England in 1542 he was defeated at the battle of Solway Moss and died a month later. He was succeeded by his daughter, Mary, Queen of Scots, who was but seven days old at his death.

James, Bushrod Washington, American oculist: b. Philadelphia 25 Aug. 1836. He was graduated from the Homeopathic Medical College of Pennsylvania in 1857, became well known as a practitioner, was elected president of the Pennsylvania Homeopathic Medical Society in 1873, of the American Institute of Homoeopathy in 1883, and in 1896 was vice-president of the Homoeopathic Medical Congress held at London, England. His publications include: 'American Climates and Resorts' (1889), a manual of climatology (1889); 'Alaskana' (1892); 'Echoes of Battle' (1895); and 'Alaska: Its Neglected Past and its Brilliant Future' (1897; rev. ed. 1901).

James, Charles, English novelist and playwright: b. London 26 Dec. 1858. He received a private education, became lieutenant-colonel of the Royal West Kent regiment, and published: 'A Bird of Paradise' (1889); 'The New Faith' (1890); 'Honors Easy' (1892); 'A Worker in Iron' (1894); 'At the Sign of the Ostrich' (1895); and 'Where Thames is Wide' (1896); etc.

James, Edmund Janes, American college president: b. Jacksonville, Ill., 21 May 1855. He was educated at Northwestern University and at Harvard, was principal of the high schools at Evanston and Normal, Ill. (1878-82), professor of public finance and administration in

the Wharton School of Finance and Economy of the University of Pennsylvania (1883-95), and professor of political and social science in the university (1894-95). In 1896 he became professor of public administration in the University of Chicago and director of the extension division, and in 1902 president of the Northwestern University. He became president of the American Academy of Political and Social Science in 1889, vice-president of the National Municipal League in 1896, and in 1891-5 was president of the American Society for the Extension of University Teaching. His writings include: 'The Legal Tender Decisions' (1887); 'The Canal and the Railway' (1890); 'The Federal Constitution of Germany' (1890); and 'The Growth of Great Cities in Area and Population' (1900).

James, Florence, "FLORENCE WARDEN," English novelist: b. Hanworth, Middlesex, 16 May 1857. She taught as a governess, 1875-80, and was on the stage, 1880-5. Her novels, many of which are strongly sensational in tone, have been very popular in this country as well as in England. They are published under the pseudonym "Florence Warden," and among them are: 'At the World's Mercy'; 'The House on the Marsh,' which established her reputation; 'A Prince of Darkness'; 'Scheherezade'; 'A Perfect Fool'; 'Pretty Miss Smith'; 'A Lady in Black' (1897); 'A Very Rough Diamond'; 'Morals and Millions'; 'One too Often' (1901); 'A House with a History.'

James, George Payne Rainsford, English novelist and historian: b. London 9 Aug. 1801; d. Venice 9 May 1860. As a young man he traveled widely on the Continent. He began his writing under the influence of Scott's novels, and wrote in all over 100 novels; he was also known as the author of popular historical books, and in 1839 was appointed historiographer royal, in this capacity writing 'History of the United States Boundary Question' and 'The Corn Laws.' In 1850 he was British consul in Massachusetts, two years later was transferred to Norfolk, Va., and in 1856 became consul general at Venice. His novels include: 'Richelieu' (written 1825, published 1829); 'Darnley' (1829); 'DeLorme' (1830); 'Philip Augustus' (1831); 'Henry Masterton' (1832); 'The Gypsy' (1835); 'Attila' (1837); 'Man at Arms' (1848); 'King's Highway' (1848); 'Agincourt' (1844); 'The Smuggler' (1845); 'Ticonderoga' (1854). His historical works include: 'Memoirs of Great Commanders' (1832); 'Life of the Black Prince' (1836); 'Life of Richard I.' (1842-9). James' novels were very popular when first written, and a new edition appeared in 1903.

James, George Wharton, American explorer, lecturer and ethnologist: b. Gainsborough, Lincolnshire, England, 27 Sept. 1858. He has spent many years in making geological and other researches in California, and elsewhere in the southwestern United States, and is a member of various learned societies in this country and England. He has published: 'The Lick Observatory' (1888); 'Nature Sermons'; 'Picturesque Southern California'; 'Missions and Mission Indians of California'; 'From Alpine Snow to Semi-Tropical Sea'; 'In and Around the Grand Canyon' (1900); 'Indian Basketry'

JAMES

(1900); 'The Indians of the Painted Desert Region' (1903).

James, Henry, American Swedenborgian theologian: b. Albany, N. Y., 3 June 1811; d. Cambridge, Mass., 18 Dec. 1882. He was educated at Union College and Princeton Theological Seminary, traveled abroad and became a Sandemanian and later a Swedenborgian. He subsequently lived in New York, Newport, R. I., and lastly at Cambridge. Among the most noted of his works on morals and religion are: 'What is the State?' (1845); 'Moralism and Christianity' (1852); 'Lectures and Miscellanies' (1852); 'The Nature of Evil' (1855); 'Christianity the Logic of Creation' (1857); 'Substance and Shadow' (1863); 'The Secret of Swedenborg' (1869). His 'Literary Remains,' edited by William James, appeared in 1885.

James, Henry, American novelist and essayist: b. New York 15 April 1843. He was the son of a clergyman, Henry James (q.v.), who gained fame as a writer on philosophico-theological subjects, first from the Sandemanian, and afterward from the Swedenborgian standpoint. The novelist, known until his father's death as Henry James, Junior, was educated under his father's guidance in New York, Geneva, Paris, and Boulogne. He lived in Europe with his parents during the years 1855-9, and after his return to the United States studied in the Harvard Law School in 1862. He began his literary career about 1865 as a contributor to American magazines, and soon afterward published 'The Story of a Year, a tale of the American Civil War.' In 1869 he took up his residence in Europe, and since then he has resided chiefly in England and Italy. 'Roderick Hudson' (1875) was his first long novel. His subsequent novels include: 'Watch and Ward' (1878), originally published in 1871 in the 'Atlantic Monthly'; 'The American' (1877), by some regarded as his best; 'Daisy Miller' (1878); 'The Europeans: a Sketch' (1878); 'Confidence' (1880); 'Washington Square' (1880); 'A Bundle of Letters' (1880); 'Diary of a Man of Fifty' (1880); 'The Portrait of a Lady' (1881); 'The Bostonians' (1886); 'Princess Casamassima' (1886); 'The Tragic Muse' (1892); 'The Other House' (1896); 'The Spoils of Poynton' (1897); 'What Maisie Knew' (1897); 'The Awkward Age' (1899); 'The Sacred Fount' (1901); 'The Wings of a Dove' (1902); 'The Better Sort' (1903). He has also written a great many short stories, among which are: 'A Passionate Pilgrim, and other Tales' (1875); 'Pension Beaurepas' (1878); 'An International Episode' (1879); 'The Madonna of the Future, and Other Tales' (1879); 'The Siege of London' (1883); 'The Point of View' (1883); 'Tales of Three Cities' (1884); 'The Author of Beltraffio, and other Stories' (1885); 'Stories Revived' (1885); 'The Aspern Papers, and other Stories' (1888); 'The Reverberator' (1888); 'A London Life, and other Stories' (1889); 'The Lesson of the Master, and other Stories' (1892); 'The Real Thing, and other Tales' (1893); 'Picture and Text' (1893); 'The Private Life' (1893), a collection of stories; 'The Album' (1894); 'The Reprobate' (1894); 'Tenants' (1894); 'Disengaged' (1894); 'Terminations, and other Sto-

ries' (1896); 'In a Cage' (1898); 'The Two Magics' (1898), consisting of two stories; and 'The Soft Side' (1900), a series of stories. In very many of his stories he describes the life of Americans in Europe, and they depend for much of their interest upon the contrasts between American and European character and institutions. Though a very prolific writer, he is never careless, his style being always felicitous, while in respect to the substance of his work he ranks as the subtlest of American novelists. A dramatic version of 'The American' was produced in London in 1891, but neither it nor his subsequent play 'Guy Domville' (1895) was successful. He has turned his intimate knowledge of modern French literature to good account in his volume of essays entitled 'French Poets and Novelists' (1878). Other works of a similar kind are 'Transatlantic Sketches' (1875); 'Portraits of Places' (1884); 'A Little Tour in France' (1884; new ed. 1900); 'Partial Portraits' (1888); 'Essays in London and Elsewhere' (1893). He also contributed the volume on 'Hawthorne' (1879) in the 'English Men of Letters' series, and in 1903 published 'William Wetmore Story and his Friends,' a notable biography.

James, Thomas Lemuel, American banker: b. Utica, N. Y., 29 March 1831. He early learned the printer's business and bought out a weekly Whig paper, the 'Madison County Journal,' at Hamilton; and in 1856 changed its name to the 'Democrat-Republican,' which was for 10 years the most powerful Republican organ in Madison County. He was collector of canal tolls at Hamilton 1854-5; was appointed inspector of customs in New York 1861; weigher in 1864; and in 1870 was promoted to be deputy collector in charge of the bonded warehouse, which department he immediately proceeded to arrange according to a new system. In 1873 President Grant appointed him postmaster of New York, and he was reappointed by President Hayes in 1877. He filled this office with signal success and originated improvements in the delivery system involving the whole postal methods of the United States. President Garfield in 1881 gave him the portfolio of postmaster-general, and his chief important service during his 10 months' incumbency was his initiation of inquiries which led to the investigation of the Star Route frauds. In 1882 he became president of the Lincoln National Bank of New York.

James, William, American psychologist and philosopher: b. New York 11 Jan. 1842. He is the son of Henry James, theologian (q.v.), and brother of Henry James, novelist (q.v.). He was educated in private schools and by tutors in New York and abroad, studied in 1861-3 at the Lawrence Scientific School of Harvard University, accompanied the Thayer expedition to Brazil in 1864-5, was graduated from the Harvard Medical School in 1870, in 1872 was appointed instructor in anatomy and physiology at the school, and in 1876 assistant professor of physiology. In 1885 he was appointed assistant professor of philosophy in the university, in 1889 professor of psychology, and subsequently professor of philosophy. He was Gifford lecturer on natural religion in the University of Edinburgh in 1899-1901. His best known work has

JAMES BAY—JAMES RIVER

been done in the domain of analytical psychology, in which he won European recognition. His works are marked by a most readable style and skilful exposition of different topics. He was a founder of the American Society for Psychological Research in 1884, and published: 'Principles of Psychology' (1890); and 'Psychology, Briefer Course' (1892), both popular text-books; 'The Will to Believe' (1897); 'Human Immortality' (1898); 'Talks to Teachers on Psychology' (1899); and 'The Varieties of Religious Experience' (1902).

James Bay, an inlet of Hudson Bay, in the southern part. The bay was named in honor of Captain Thomas James, an English navigator, who explored this body of water in 1631–3. The bay is about 320 miles long and from 140 to 160 miles wide. It contains a number of islands, the largest, Agomska, being about 70 miles in length. Several large rivers flow into James Bay; the Albany, Moose, Noddaway, and East Main are the largest. Moose Factory, at the mouth of Moose River, on the southern shore, is the most important Canadian trading station, next to York Factory, of the Hudson's Bay Company.

James, Epistle of, an encyclical letter addressed to the Jews of the Dispersion. It was written by a Jew for Jewish readers, all of whom are supposed to be subject to the Jewish law. Its date is about 50 A.D., at latest, certainly before the fall of Jerusalem. The epistle was not at first admitted into the canon, and it is not much quoted by the earlier writers, Origen indeed being the earliest we find quoting it by name. Eusebius places it in his list of books controverted but recognized by most (*Antilegomena*), and Jerome expresses the doubt more strongly still. It was finally declared canonical by the third Council of Carthage (397), and already we find it acknowledged by Cyril of Jerusalem, Epiphanius of Cyprus, Athanasius, Gregory of Nazianzus, and all later theologians, down to the time of the Reformation, when it was rejected by Erasmus and Cardinal Cajetan, and stigmatized by Luther as "a downright epistle of straw . . . with nothing evangelical about it," although Calvin thought that it was worthy of an apostle.

The aim of the epistle is throughout ethical rather than doctrinal, Christianity being prominently put forward as the ethical fulfilment of the law, the perfect man being he whose faith has constantly proved itself in practice, and who is patient under all tribulation. It echoes closely the language and method of Christ himself; as Beyschlag says, "essentially it is the teaching of Christ, and thus there is little teaching about Christ." Besides the discourses of the Master, especially his Sermon on the Mount, we find distinct traces of familiarity with the Wisdom of Solomon, and the Ecclesiasticus of the son of Sirach. Formalism, greed of gain, respect of persons, falsehood, evil-speaking, boasting, wrangling and bitterness in debate, attention to dogmatic definitions instead of holiness of life—such are the sins against which the author inveighs with vivid and abrupt invective. His Greek is unusually pure, and some scholars, as Schmidt, Bertholdt, and Bishop Wordsworth, have supposed that the epistle was first written in Aramaic and afterward translated.

The passage in the second chapter (14–26) has been interpreted by many theologians as a direct attack on the Pauline view of faith and justification, that Christ by his death had accomplished a new order of salvation, in which the law, which was merely temporary, was now abrogated, and that thus Christianity had fitted itself to become a universal religion; but Paul's conception is more philosophical and comprehensive, although it by no means excludes the conception of James, whose faith without works is not Paul's justifying faith at all, but the profitless faith without love condemned in I Cor. xiii.

The Tübingen school, as might have been expected, claimed the Epistle of James as a polemic against Paul, and made its author a pseudonymous writer of later time, who employed the name of James as an accepted type of spiritualized Jewish Christianity.

Bibliography.—Besides the general introductions of Bleek, De Wette, S. Davidson, Hilgenfeld, Holtzmann, Salmon, Dods, and Weiss, and the works on the New Testament canon by Kirchofer, Overbeck, Westcott, and Zahn, may be consulted the special commentaries by Bassett (1876), Reuss (1878), Erdmann (1881), Schegg (1883), E. H. Plumptre (1884), Beyschlag (1888; the 5th ed. of the commentary in the 'Exegetisches Handbuch'), and R. Johnstone (2d ed. 1888).

James Island, an island in Charleston harbor, in South Carolina. It is separated from the city of Charleston by the Ashley River and the South Channel of the harbor, here a little over a mile wide. On the northeast coast of the island is Fort Johnson and nearby a quarantine station. Just northeast of the island is Fort Sumter (q.v.). The battle of Secessionville, fought on 16 June 1862, and several other engagements of the Civil War, took place on this island.

James Milliken University, an organization which includes three institutions of learning: the Lincoln College, located at Lincoln, Ill.; the Industrial School and the Decatur College, at Decatur, Ill. The synods of the Cumberland Presbyterian Church of Iowa, Indiana, and Illinois, founded, in 1865, the Lincoln College. Schools of art, music and elocution, a classic college, and a preparatory department, at times a commercial school, all made up Lincoln College. The Decatur College and Industrial School are endowed institutions opened in 1903. In 1900–01 a fund for a university was provided by gifts from James Milliken, an appropriation from the Cumberland Presbyterian synods of Iowa, Illinois, and Indiana, and donations from the citizens of Decatur. The three schools mentioned were united in the James Milliken University, but each one retains to a certain degree its own independence.

James River, a stream which has its rise in Wells County, in North Dakota, and flows south into South Dakota, and in a southerly direction across the State into the Missouri River. Some of the largest cities and towns of the interior of both North and South Dakota are on or near the James River; Aberdeen, Huron, Mitchell, and Yankton near the mouth, in South Dakota; and Jamestown in North Dakota. It is about 450 miles long.

James River, the largest river in Virginia, has its rise in the western part of the State, in

JAMESON — JAMESTOWN

the Alleghany Mountains; the head-waters are the Jackson and Cowpasture rivers which unite at Covington, in Virginia. The James flows southeast to Buchanan, in Botetourt County, then northeast to Balcony Falls, where it breaks through the Blue Ridge Mountains, again southeast to Lynchburg, then northeast to Scottsville, from which point the general course is southeast to the Chesapeake Bay. Its length is about 450 miles. At the Rocketts, just below Richmond, where the river becomes a tidal stream, is the head of navigation for steamboats of 130 tons, about 150 miles from the mouth. Ocean steamers come up the river as far as City Point, at the mouth of the Appomattox River. From City Point to the mouth, 66 miles, the stream is really a broad, deep estuary with Hampton Roads (q.v.) at its entrance to the Chesapeake. The falls in the river at Richmond, about 100 feet in six miles, furnish a large amount of water power. From Richmond to Buchanan, a distance of nearly 200 miles, the Kanawha Canal follows the course of the river and utilizes extensive reaches of slack water navigation. The chief tributaries of the James are the Chickahominy (q.v.) from the north, and the Appomattox from the south. The broad body of water at the entrance into Chesapeake was early explored by European navigators, and Jamestown (q.v.), the first permanent English settlement, was located on this river.

Jameson, jā'mē-sōn, Anna Brownell Murphy, English author and art critic: b. Dublin 17 May 1794; d. Ealing, Middlesex, England, 19 March 1860. In 1827 she was married to Robert Jameson, afterward speaker of the House of Assembly of Upper Canada, and attorney-general, but the union proved unhappy. She made her first appearance as an authoress by the publication of the 'Diary of an Ennuyée' (1826), which was very favorably received. Her 'Loves of the Poets' appeared (1829), and was succeeded by 'Memoirs of Female Sovereigns' and 'Characteristics of Shakespeare's Women.' In 1836 Mrs. Jameson visited her husband in Canada, and published 'Winter Studies and Summer Rambles in Canada' (1838). Later works of hers include: 'Handbook to the Public Picture-galleries of Art' (1842); 'Companion to the Private Galleries of Art in London' (1844); 'Memoirs of the Early Italian Painters' (1845); 'Memoirs and Essays on Art, Literature, and Social Morals' (1846); 'Sacred and Legendary Art' (1848); 'Legends of the Monastic Orders' (1850); 'Legends of the Madonna' (1852). In these the author has given admirable expositions of the works of the old masters and the religious bearings of mediæval art. Few writers have done so much to refine the public taste, and diffuse sound canons of art criticism. Consult: Macpherson, 'Memoirs of the Life of Anna Jameson' (1878).

Jameson, John Franklin, American historical writer: b. Boston 1 April 1859. He was graduated from Amherst College in 1879 and was professor of history at Brown University 1888-1901. He has been managing editor of the 'American Historical Review' from 1895 and the head of the department of history at the University of Chicago from 1901. He has published 'History of Historical Writing in America' (1891); 'Dictionary of United States History' (1894); etc.

Jameson, Leander Starr, Scottish physician, administrator, and freebooter: b. Edinburgh 8 Feb. 1853. He studied medicine in Edinburgh and London, began professional practice at Kimberley, Cape Colony, in 1878, in 1891 became administrator of Rhodesia for the British South Africa Company, and in 1895 led the now well known raid into the Transvaal. During disturbances between the Boers and the Uitlanders, or foreigners, in the South African Republic, Jameson had, by order of Cecil Rhodes (q.v.), then premier at the Cape, assembled a Rhodesian military force on the Transvaal border, to act in case of emergency. On 29 December, with 600 troopers, Jameson, proceeding on his own judgment, entered the South African Republic for the support of the Uitlander party. His force was compelled to surrender to the Boers at Doornkoop on 2 Jan. 1896. Jameson, with his officers, was handed over by President Kruger to the British government for trial. He was sentenced, May 1896, to ten months' imprisonment, but in December was released because of illness. In 1897 he returned to Rhodesia, and in the second Boer war served in the English army. Jameson's surrender was followed by a congratulatory message to Kruger from the German emperor which for a time threatened serious consequences.

Jameson, Patrick Henry, American physician: b. Monroe Township, Jefferson County, Ind., 8 April 1824. At 19 he went to Indianapolis, taught school there four years, studying medicine meanwhile, and was graduated from Jefferson Medical College, Philadelphia, in 1849. He then returned to Indianapolis, where he became very prominent as a physician. During the Civil War he served as military surgeon and was commissioner of the Indiana hospital for the insane, 1861-80. He was likewise active in the establishment of the Indianapolis city hospital and in the organization of the University of Indianapolis, and was for 30 years a director of Butler College, at Indianapolis. From 1863 to 1869 he was a member of the Indianapolis common council and compiled the city ordinances in 1865. He has published 'Memoirs of Prominent Physicians of Indianapolis.'

Jameson Raid, The. See JAMESON, LEANDER STARR.

Jamestown, jāmz'town, N. Y., city in Chautauqua County, on the Conewango Creek, which is the outlet of Chautauqua Lake; and on the Erie and the Jamestown & C. L. R.R.'s; about three miles from Chautauqua Lake, 25 miles from Lake Erie, and 70 miles, by rail, southwest of Buffalo. Lake steamers and trolley cars connect it with a number of the nearby towns. The first permanent settlement was made in 1810, by settlers in search of agricultural lands. The location, so near the outlet of the lake and in the midst of a fertile agricultural region, attracted settlers, and in 1815 the town was planned; and was incorporated as a village in 1827. The country around developed rapidly, but Jamestown was not chartered as a city until 1886. The chief manufactures are furniture, woolen goods, photographic paper, metallic goods, boots and shoes, agricultural implements, and brooms. It has saw-mills, canning factories, lumber and brick yards. The city has the James Prendergast Free Library, containing about 17,000 volumes, and an excellent high school.

JAMESTOWN — JANE EYRE

The municipal officers are a mayor, who holds office two years, a city council, a clerk, overseer of the poor, sealer of weights and measures, constables, assessors, justices of the peace, and police justices, all of whom are elected by the people. Other subordinate officials are appointed by the mayor subject to the approval of the council. Jamestown was the home of Reuben E. Fenton (q.v.). There are about 8,000 Swedes now living in Jamestown. Although they are adopted citizens, those born in Sweden still use their native language in the homes; and they have their own Swedish papers and literature. Pop. (1890) 16,038; (1900) 22,892.

Jamestown, N. D., city, county-seat of Stutsman County; on the James River, and on the main line and a branch of the Northern Pacific railroad; about 80 miles west of Fargo, on the Red River of the North, and 100 miles east of Bismarck on the Missouri River. It is situated in an agricultural region, noted for its extensive wheat fields and large stock farms. Some of the industrial establishments are flour-mills, grain elevators, stock-yards, wholesale groceries, lumber and brick yards. It is the trade centre for a large extent of country, and the small towns off the railroad procure their local supplies of manufactures and groceries from Jamestown. Pop. (1900) 2,853.

Jamestown, Va., in James City County, the first permanent English settlement in the New World, and capital of Virginia 1607-98; on what was a peninsula of the James River some 32 miles from its mouth, nearly opposite the present Williamsburg, with a neck overflowed at high tide, and since then washed away, leaving the place an island; the front also has been eaten away by the river, so that the site of the original huts is submerged. It was ill chosen and malarious, and the place never prospered; but no towns did in early Virginia. It was founded 13 May 1607 by the company of Gosnold, Wingfield, John Smith, etc., with Capt. Newport; and was first a triangular wooden blockhouse called Fort James, after the king, around which some huts sprang up. These were entirely destroyed by fire in 1608, but soon rebuilt. In 1609 there were 50 or 60 wooden houses of one and two stories, with a chapel and a storehouse, surrounded by a log palisade 15 feet high, and with a fort at the neck. During the Starving Time of 1609-10 it was nearly depopulated, and on 7 June 1610 the remnant deserted it and started for England; but meeting Lord Delaware with provision ships at the mouth of the river, all turned back and reoccupied it. Delaware found the chapel "ruined and unfrequented." In 1616 John Rolfe says there were 50 inhabitants. By 1619 a church of hewn timber 50 x 20 had been built; in July 1619 the first legislative assembly in America was held there. A timely warning enabled its inhabitants to escape the great Indian massacre of 1622, and it was a place of refuge for those outside it. The first brick edifice in Jamestown was erected in 1640; a brick church some time after; between 1676 and 1684 was built the brick church whose ivy-mantled tower still stands, and which is incorrectly supposed by many tourists to be the one in which Rolfe married Pocahontas. About the same time a

more ambitious fort was begun, with a magazine still traceable; but so injudiciously located for guarding the river-channel that it was above instead of below the place to be defended. Jamestown has little history separate from the colony thence till Bacon's Rebellion (q.v.); as Berkeley's capital, it was burnt to the ground by Bacon, that it might no longer "harbor the rogues." Again rebuilt, in the last decade of the century it was once more destroyed by fire, and never rose from its ashes. It had long been dwindling, and removal of the capital had been mooted, and in 1698 Williamsburg was made the capital. Till very recent years the ruins of Jamestown were left to sink gradually into the encroaching river; but some years ago the Association for the Preservation of Virginia Antiquities bought it, and with the help of the national government have built a sea-wall and saved the relics from further destruction. Besides the church tower, a few tombstones and remains of two or three houses still exist. Consult Tyler, 'Cradle of the Republic' (1900).

Jamestown Weed. See DATURA.

Jamieson, jā'mi-sōn, **Cecilia Viets Dakin**, American novelist: b. Yarmouth, N. S., 1848. She was married in 1878 to Samuel Jamieson of New Orleans. She has published 'The Story of an Enthusiast': a novel (1887); 'Lady Jane'; 'Toinette's Philip'; 'Seraph'; 'The Little Violinist'; 'Woven of Many Threads'; 'The Lily of San Miniato'; etc.

Jan Mayen, yān miēn, an island in the Arctic Ocean, about 250 miles northeast of Iceland; area, about 160 square miles. It is volcanic, with an irregular surface, mountainous near the extinct volcano, Beerenburg, about 6,500 feet in height. One of the active volcanoes is about 1,500 feet high. There are some large glaciers on the island, one near Beerenburg. Vessels from Norway and Scotland occasionally visit the island. In 1882-3 scientists from Austria lived on the island for some months, engaged chiefly in making meteorological observations. The island was named after Jan Mayen, a Dutch navigator, who discovered the land in 1611. Later it was ascertained that Henry Hudson visited the island in 1607.

Janauschek, yā'now-shēk, **Fanny** (FRANZISKA MAGDALENA ROMANCE), American actress: b. Prague, Bohemia, 20 July 1830. She first went upon the stage in Cologne, playing in that city and also in Frankfort, 1848-60, and subsequently played in Dresden and the principal cities of Germany. In 1852 she was married to Captain Frederick Pillot, of the German navy. She made her first tour in America, 1867-9, playing in the German language and securing most favorable notice. Returning to Germany she studied English, and in 1873 made her second visit to the United States, when she played in English the most exacting Shakespearian roles. She has also been very successful in such roles as Meg Merrilles, Mary, Queen of Scots, and in double roles, as in 'Bleak House' and other plays. She retired from the stage in 1898, making her home in Brooklyn, N. Y.

Jane Eyre, ār, a famous novel by Charlotte Brontë, published in 1847. In the character of Jane Eyre, the young authoress first found an outlet for the storm and stress of her own

JANES — JANSEN

nature. The book is therefore autobiographical in the truest sense.

Janes, Edmund Storer, American Methodist Episcopal bishop: b. Sheffield, Berkshire County, Mass., 27 April 1807; d. New York 18 Sept. 1876. In 1830 he entered the Methodist ministry in the Philadelphia conference, in 1835 became financial agent for Dickinson College, in 1840-4 was financial secretary of the American Bible Society, and in 1844 was elected bishop. In connection with his episcopal duties he traveled widely in the United States and abroad, and subsequent to the Civil War aided in the reorganization of his Church. He had some reputation as a preacher.

Janes, Lewis George, American scholar and author: b. Providence, R. I., 19 Feb. 1844; d. Greenacres, Maine, 5 Sept. 1901. He was president of the Brooklyn (N. Y.) Ethical Association in 1885-96, lecturer on sociology and civics in the School of Political Science there in 1893-6, and in 1896 became director of the Cambridge (Mass.) conferences and the Monsalvat school of comparative religion. In 1899 he was elected president of the Free Religious Association of America. Among his works are: 'A Study of Primitive Christianity' (1887); 'The Evolution of Morals' (1889); 'Life as a Fine Art' (1891); 'War and Progress' (1893); 'Cosmic Evolution as Related to Ethics' (1895); 'Social Ideas and Social Progress' (1899); and 'Health and a Day' (1901).

Janesville, jānz'v'il, Wis., city, county-seat of Rock County; on the Rock River and on the Chicago, M. & St. P. and the Chicago, N. W. R.R.'s; about 85 miles northwest of Chicago and 60 miles southwest of Milwaukee. The first permanent settlement as a village was in 1837, and it was chartered in 1853. Janesville is located in an agricultural region, noted for the amount and quantity of tobacco raised. The chief manufactures are agricultural implements, foundry products, wagons and carriages, furniture, cotton and woolen goods, boots and shoes, flour, fountain pens, and school supplies. It has large lumber and brick yards, storage houses, and stock yards. Its principal trade is in its own manufactured goods, farm and dairy products. Some of its principal buildings are the State School for the Blind, the Saint Joseph's Convent, the Y. M. C. A. buildings, two hospitals, the churches, high school, public library, court house, and city hall. The mayor holds office for two years. The mayor, council, board of education, attorney, city clerk, treasurer, sealer of weights and measures, and justices of the peace are chosen by popular election. The mayor appoints, subject to confirmation by the council, the directors of the public library; the council elects the city engineer, the assessors, and the street commissioners. The members of the fire and the police departments are selected from the eligible civil service lists. From 1885 to 1903 there has been a constant and healthy expansion in industrial and commercial lines. Pop. (1890) 10,836; (1900) 13,185.

Janiuay, hā-ne-wī, Philippines, a pueblo of the province of Iloilo, Panay, situated 18 miles northwest of the town of Iloilo, near the Jalaur River. It lies in a hilly country and petroleum has been reported in the vicinity. Pop. 28,700.

Janizaries, jān'ī-zā-rīz (Turkish, *jeni-tcheri*, new soldiers), an infantry force of Turkey, first

organized by the Sultan Orkhan about 1330, and in 1362 increased to about 10,000 by Amurath I., who gave them considerable importance by bestowing on them special privileges. The janizaries thus became a class of warriors so deeply imbued with the military spirit that they proved in many instances a means of salvation to the empire. It was their boast that they had never fled in battle, and they were the nerve and sinew of the Ottoman army. The regular troops of janizaries at one time amounted to 60,000 or more, but they were afterward reduced to 25,000. They were kept in barracks in Constantinople and a few other cities. The irregular troops amounted to 300,000 or 400,000, and were scattered among all the cities of the empire, in time of peace performing police duties. The janizaries who constituted the sultan's bodyguard became in time so dangerous and their insurrections so frequent that several unsuccessful attempts were made to reform or disband them. In 1826 they rebelled on account of a proposal to form a new militia, when the sultan, Mahmoud II., having displayed the flag of the Prophet, and being supported by their commander-in-chief, defeated the rebels and burned their barracks, when many of them perished in the flames. A royal proclamation abolished the corps. As many as 15,000 were executed, and fully 20,000 were banished.

Janko (yōn'kō) **Keyboard**, a keyboard for the pianoforte, invented 1882 by Paul von Janko; introduced in London 1888, in New York in 1890. It consists of six rows or banks of keys arranged like a fan, placed in a semi-circle. Each note has three different keys. The keyboard can be attached to any pianoforte, grand, upright or square.

Jans, Anneke, än'nā-kē yäns (or ANNETJE), Dutch colonist in America: d. Albany, N. Y., 1663. She came from Holland to New Netherland in 1630 with Roeloff Jansen, her husband, who secured in 1636 a grant of a tract of land containing 62 acres and reaching from the Hudson to the present Broadway and from a point near Desbrosses Street to Warren Street. In 1654, Anneke, upon the death of her second husband, Everardus Bogardus (q.v.), obtained in her name a patent-right to the tract. In 1671 the land was sold by the heirs to the English Governor Lovelace. Three of the heirs, however, did not sign the document. Subsequently the property was confiscated by the English government and deeded to Trinity Church corporation (1705). From 1749 the possession of the property has been the subject of numerous suits by the heirs, based chiefly on the omitted signatures, and all decided for the defendants.

Jansen, yān'sēn, or jān'sēn, **Cornelius**, Dutch theologian: b. near Leerdam, Holland, 28 Oct. 1585; d. Ypres, Belgium, 6 May 1638. From his 17th year he applied himself to the study of theology and first came into notice while professor of theology at Louvain (1630), as a teacher of the most rigid Augustinianism, especially in connection with the doctrine of free will and divine mercy. This brought him into conflict with the Jesuits. He was appointed (1636) bishop of Ypres, where he completed his famous work, on which he had labored for 22 years, under the title 'Augustinus, sive Doctrina Sti. Augustini de Humanæ Naturæ Sanitate, Ægritudine, Medicina.' In this he

JANSENISM—JAPAN

declared philosophy, especially that of the Aristotelians, to be the source of Pelagian error, and in accordance with rigid Augustinianism, maintained the utter corruption of human nature and the extinction of free will, together with predestination. The school of thought he thus founded is now known as Jansenism (q.v.).

Jansenism, jān'sen-ism, the teaching of the Jansenists, a sect of Christians still existing in the Netherlands and named after Cornelius Jansen, bishop of Ypres. They profess to hold the truth as it was taught by Augustine, bishop of Hippo, and prefer to be called 'Disciples of St. Augustine.' The free grace of God, the free will of man, and predestination, in the Augustinian sense, formed the main articles of their belief. The Jansenists were, however, accused of reviving the teaching of Michael Baius (1513-80) which had been pronounced heretical by Popes Pius V. and Gregory VIII. Baius taught that original justice is an integral part of human nature, and not a free gift of God; that fallen man, being utterly depraved in his nature, is incapable of doing good; that all actions of man in the natural order are sinful, and that divine grace compels men to be and do good, without the concurrence of their will. The book of Jansen was condemned by Urban VIII. in his 'In Eminentia' (1642), but the pope's decree was not generally accepted in Flanders. The Jesuit Molina and the Molinists, his followers, supported views opposed to those of Jansen. Alexander VII. declared that the errors attributed by the Molinists to Jansen, and which the Jansenists said could not be found in 'Augustinus' were held and enunciated by Jansen. The Port Royalists, Arnauld, Nicole and Pascal, wrote famous books defending Jansen against the Jesuits.

In 1679 Arnauld and his followers were constrained to take refuge in the Netherlands. In 1702 the Sorbonne decided that a priest accused of Jansenism could grant absolution. In 1694 Quesnel's 'Moral Reflections' were published and the controversy had been revived. In his bull 'Unigenitus,' Clement XI. condemned the Jansenist passages in Quesnel's work and the author fled to Brussels, and died in Holland 1719. The Jansenists of Utrecht number about 8,000; they profess to be Roman Catholics, are governed by an archbishop, to whom, however, the pope always refuses confirmation and the gift of the palla. They reject the bull 'Unigenitus' and published a protest against the dogmas of the Immaculate Conception, and Papal Infallibility. Consult: Reuchlin, 'History of Port Royal' (1844); Fuzet, 'Les Jansenistes du 17me Siècle' (1877); Jervis, 'History of the Church of France' (1872). See PASCAL, BLAISE; ARNAULD.

Janssen, John, American Roman Catholic bishop: b. Keppeln, Rhine Province, 3 March 1835. He pursued theological courses in the seminary of Münster, and in 1858 in the United States, was ordained priest in 1858, was in missionary work at Springfield and Alton, Ill., was vicar-general of Alton diocese in 1870-7 and 1879-86, and in 1888 was consecrated bishop of Belleville, Ill.

Januarius, jān-ū-ā'rī-ūs, Saint: b. Naples or Benevento, Italy, 21 April 272; d. Pozzuoli, Italy, 19 Sept. 305. He became bishop of Benevento in 303 and at the time of the persecution

of the Christians by Diocletian was beheaded. He is the patron saint of Naples. His body lies in the crypt of the cathedral at Naples; and two phials of his blood which a pious matron caught, according to tradition, at his execution, are preserved in a chapel in the south aisle. It is asserted that the blood liquefies on being brought near the head of the saint. A trial is made on three festivals of each year, the chief of which is the anniversary of the martyrdom, and also when public danger and calamity exists or is impending. It is believed that the patron saint is particularly propitious if the blood moves briskly in the phials and appears of a clear red, while the opposite is regarded as presaging some ill to the country.

January, the first month of the year, was by the Romans held sacred to Janus, from whom the name was derived. The Roman year originally began with March, and consisted of only ten months. Numa is said to have added January and February to the calendar; but although the Romans as early as 251 B.C. accepted January as the first month of the year, the nations of Europe did not universally adopt it as such till the 18th century. The 25th of March was the beginning of the ancient Jewish year, and that day, instead of 1 January, long held a legal position in Christian countries as the opening of the new year.

Janus, jā'nūs, an ancient Latin divinity, after whom the first month of the year was named. He was held in great reverence by the Romans, and was represented with two faces, one looking forward, the other backward. All doors, passages, and beginnings were under his care. His principal festival was New Year's Day, when people gave each other presents. The temple of Janus, which was open in time of war and closed in time of peace, was shut only three times in the long space of 700 years.

Janvier, jān've-ā, **Thomas Allibone**, American author: b. Philadelphia, Pa., 16 July 1849. He received a common school education; was an editorial writer for the *Philadelphia Press, Bulletin, and Times* in 1870-81; lived in New York during most of the period 1884-94, and then made his residence in France and England. Among his works are 'The Mexican Guide' (1887), 'The Aztec Treasure House' (1890), and 'Stories of Old New Spain' (1891), material for which was largely derived through visits to Mexico and New Mexico; 'An Embassy to Provence' (1893), the chronicle of a European journey; 'In Old New York' (1894), popular historical sketches; 'The Passing of Thomas, and Other Stories' (1900); 'In Great Waters' (1901); 'The Dutch Founding of New York' (1903).

Japan, an empire off the northeast coast of Asia, consisting of an archipelago in the North Pacific Ocean. Besides Nippon or Hondo, Kiusu, and Shikok, three large mountainous and volcanic islands, with about 500 smaller islands, forming Old Japan or Japan proper, it comprises the outlying large island of Yezo or Hokkaido, north of Hondo, separated by Tsugarn Strait; the long chain of the Kurile Islands between Yezo and Kamchatka; the Loo-choo or Liu-Kiu Islands, stretching southwestward toward Formosa, and lastly Formosa and the Pescadores Islands, acquired as a result of the

JAPAN

war with China in 1804. The Japanese dominions which extend between lat. 24° and 49° N., and lon. 120° and 150° E., are separated from the Asiatic continent by the Sea of Okhotsk, the Sea of Japan, the Strait of Korea, Tong Hai or the Eastern Sea, the Strait of Tokien or Formosa, and are distant from China 420 miles, from Kamchatka 270 miles, and from California, 5,000 miles. The area of Japan proper is estimated at 111,239 square miles, of which Hondo, the main island, occupies 87,846; Kiusiu 16,839, and Shikok 6,932 square miles. Yezo has an area estimated at 36,300 square miles, and adding the Kurile and Loo-Choo Islands, and Formosa (area 13,300 square miles), the total area of the empire is fully 160,000 square miles. The native term *Nippon*, *Nipon*, or *Dai Nippon*—‘Great Nippon,’ the latter word meaning “Sunrise” or “East,” a former specific name for the largest island of the group, is really the name of the empire, the Japanese now calling this island Hondo or Honshiu. The capital of the empire is Tokio or Yeddo; other important towns are Osaka, Kioto, Nagoya, Kobé, Yokohama, Hiroshima, Nagasaki.

Political Divisions.—Japan anciently divided by native geographers into the eight great divisions of Gokynay, Tokaydo, Tosando, Fukurokudo, Sanindo, Sanyodo, Nankaydo, and Saykaydo, subdivided into 68 provinces or principalities, and these again into 622 districts, now comprises for Japan proper the three great fu or residential districts of Tokio, Kioto, and Osaka, and 43 ken or rural prefectures, Yezo and Formosa having minor subdivisions for administrative purposes.

Physical Features.—The largest island, Hondo, is upward of 700 miles long northeast and southwest, breadth varying from 50 to 100 miles; Kiusiu, on the southwest, separated from Hondo by the Strait of Shimonoseki, which in one part is narrowed to 2 miles width, is about 200 miles long north to south and 120 miles broad; Shikok, the third and smallest of the three principal islands, is 140 miles long by 60 miles broad. It lies east of Kiusiu, and is separated from it by the Strait of Bungo, which at its narrowest part is not more than 10 miles broad. The straits which divide Shikok from Hondo are scarcely broader, and are thickly set with small islands. The more or less enclosed stretch of sea between Kiusiu, Shikok, and Hondo is known as the Inland Sea. Yezo is of a roughly triangular form, having its sides respectively 300 miles, 260 miles, and 220 miles in length. It is separated from Hondo on the southeast by the Strait of Tsugar, Matsmai, or Sangar, about 8 miles broad in the narrowest part. West of Hondo lies the important island of Sado. The coasts of the larger islands are extremely irregular, being deeply indented with gulfs, bays, and inlets, which form magnificent harbors, although in the north especially, they are difficult of access, not only from the multitude of rocks and islands that surround them, but from the prevalence of gales and fogs. Though there are some large plains, the surface of the country is in general very much broken by hills and valleys, and in many instances rises into mountains of great elevation. This is especially the case in the main island, which is traversed throughout its whole length by a regular chain of mountains, the highest peak of which, Fusi-yama (Rich Scholar Peak)—a

dormant volcano, covered with perpetual snow—is 13,977 feet high; but the elevation of the range is in general so low as to admit of cultivation up to the watershed of its streams. The Japanese islands form a part of the line of volcanic action which commences, in the north, with the Aleutian Isles, passes through the Philippines, Sumbawa, and Java to Sumatra, and then in a northwest direction to the Bay of Bengal. The volcanic vents, which indicate the direction of the line, are numerous in Yezo, Hondo, and Kiusiu; earthquakes, often causing great devastation, are of frequent occurrence, and it is calculated that every seven years a Japanese city is destroyed by their agency. In Yezo some dreadful eruptions have occurred—one in 1783 destroyed 23 villages; and the volcano of Wunzendake, one of five active in the island of Kiusiu, is the terror of the surrounding inhabitants—an eruption of it in 1792 having destroyed 53,000 people. Almost equally disastrous was the tidal wave in 1866, which, besides causing the death of over 26,000 people, injured many thousands more, and destroyed a vast amount of property.

Hydrography.—Streams are numerous in Japan, but have very short courses and are for the most part rather torrents than rivers. Though valueless as channels for the development of commerce they are of great value for the purposes of irrigation. The principal rivers or gawas of the main island are: the Shinanogawa, which rises in Shinano, and after a northward course of 320 miles flows into the Sea of Japan; the Tonegawa, which rises in Kodzuke, and after a course of 170 miles flows into the Pacific near Tokio; the Kisogawa, which enters the gulf of Izeh; and the Yodogawa, the outlet of Lake Biwa, which flows into Osaka Bay. Ishikari in Yezo is the longest river of Japan, having a course of 407 miles. There are a number of lakes scattered throughout the islands, the largest being Biwa or Omi, in the southern part of Hondo, about 40 miles long.

Geology and Mineral Resources.—The prevailing formations in these islands are trachyte and basalt; plastic clay, marl, and feldspar occur in various localities; and there are whole mountains of porcelain earth. The metallic wealth of the empire is known to be very great, comprising gold, silver, copper, tin, lead, and iron. The island of Sado is particularly mentioned as rich in gold. Both the tin and copper of Japan are considered to be of very superior quality. Coal is found in various parts, and the output is rapidly increasing, though it does not as yet much exceed 6,000,000 tons annually. Petroleum is becoming a product of some consequence. Sulphur abounds; thermal and mineral springs are of frequent occurrence; and ambergris is met with on some of the shores. Among the precious stones are agates, carnelians, and jaspers of great beauty, while pearls, frequently of large size, are found in the shell fisheries around the islands.

Climate.—The climate of Japan, though extremely various—being intensely cold in the north, and warm in the south—is, on the whole, much milder than its latitude would indicate; owing, chiefly, to the influence of the surrounding ocean. A remarkable difference of climate exists also between the east and west shores; the cold being more intense on the

JAPAN

latter than the former, owing to the proximity of the Asiatic continent; while the east coasts are protected from the cold continental winds by the lofty central ridge of mountains that traverses the islands north to south. From March to the second half of May a splendid spring prevails; from June to September summer extends, introduced by heavy rains followed by intense heat; from September to the end of November there is a brilliant autumn; and three months of winter succeed, rendered not unpleasant by the continued serenity of the sky. In Kiusiu, and in the south parts of Hondo, the thermometer ranges between 29° and 104^b F., 80° being the average in the middle of summer, and 35° in the coldest months of winter. In lat. 32° N. ice is formed of several lines in thickness; in lat. 36° the lakes are covered with a sheet of ice, and in 38° to 40° the ice becomes so thick that the rivers may be crossed upon it; while in Yezo, near Cape Saga, lat. 45° 21' N., winter is so severe as to drive the hardy Ainos to the protection of caverns. Rain is very frequent; hurricanes and water-sprouts also occur often, and typhoons and equinoctial gales frequently sweep the seas about the change of the monsoons.

Forestry.—The forests of Japan cover an area of 20,62 square miles and, especially in Yezo, form a source of wealth that is as yet comparatively neglected. Japan produces most of the trees common to temperate regions. The fir and cedar grow to immense size, the latter sometimes to the diameter of 18 feet. Of the oak, two species are peculiar to the country; their acorns when boiled form a palatable and nutritious article of food. The mulberry and the varnish tree grow wild. The nuts of the latter yield solid oil for candles, as do those of the camphor tree, which lives to a great age, and attains a great size. A camphor tree observed by Kampfer in 1691 was then 36 feet in circumference, the same tree measured by the Dutch traveler Siebold in 1826 was 50 feet in circumference. The people cut the root and stem into small pieces, and procure the camphor by decoction. It has long formed an important article of export. Chestnut and walnut trees are found.

Flora.—The flora as a whole resembles that of a great part of North America. The vegetation is exceedingly various, the products of the tropics being intermingled with those of the temperate and frigid zones. The palm, banana, bamboo, bignonia, and myrtle flourish. Sweet oranges, pomegranates, pears, apricots, peaches, and above 500 of the principal ornamental and useful plants are of foreign origin, having probably been introduced from Korea and China. The *kadsi*, or paper-tree, a species of mulberry, grows naturally in the fields, and furnishes textile fibres from which paper is produced; paper is also made from various other plants. The chrysanthemum is a common and favorite plant, and has become an emblem of Japan. The camellia, cultivated in several hundred varieties, grows to a large size, and is a great favorite both for the beauty of its leaves and of its flowers.

Fauna.—In consequence of the general cultivation of the soil the wild animals are necessarily few in number; but bears, hyenas, deer, hares, foxes, and wild boars are still found in the north of Hondo. Dogs are common; there

is a small highly prized species of spaniel, from which it is supposed was derived the English variety known by the name of King Charles. Though cats exist in thousands, the country is said to be overrun with rats and mice. Among the animals are flying-squirrels and monkeys. There is a great variety of birds—including song-birds, birds of prey, birds of the pheasant kind, and in particular numerous water-birds, of which the cormorant is trained to catch fish for its owner. Snakes are not unfrequent, and at least one species is venomous; there are also tortoises, lizards, scorpions, and centipedes; and of the insect tribes there are white-ants, winged grasshoppers, and several beautiful varieties of moths. The seas abound in fish, which are taken in great quantities. The rivers of Yezo supply abundance of salmon.

Agriculture.—The soil of Japan is naturally indifferent; but the patient industry of the agriculturists, favored by the genial climate, has covered with vegetation every spot capable of bearing anything. The rugged mountain sides, where the plow cannot be used, are often built up in terraces, and tilled by hand. Agriculture is greatly promoted by a law which provides that land remaining unused for more than a year shall become forfeited to the public. The agriculture of the Japanese is conducted with diligence and skill. Irrigation is judiciously applied, and manure of all kinds is carefully collected and used in the production of generally abundant harvests. In the south the sugar-cane is cultivated with success; and rice yields two harvests, and constitutes the chief article of food. Wheat and barley, maize and millet, are grown to an important extent, and buckwheat, potatoes, melons, pumpkins, and cucumbers in great abundance. Ginger, pepper, cotton, hemp, and tobacco are cultivated in considerable quantities; and there are extensive plantations of the tea plant—yielding, however, a produce inferior to that of China. Silk is also a Japanese product of importance. The gardeners of Japan have attained the art of dwarfing and also of unnaturally enlarging all vegetable productions. They exhibit in the miniature gardens of the towns full-grown trees of various kinds only three feet high, with heads of about the same diameter. They will grow in a box 4 inches long, 1½ wide, and 6 high, a bamboo, a fir, and a plum tree, the latter in full blossom, asking for this portable grove about \$500. The growth of trees is sometimes so stimulated that the branches stretch to a great distance from the trunk, and are supported on props.

Stock-raising.—Buffaloes and zebras are common; but they are used only for carrying burdens and for agricultural purposes. Horses of various breeds—but generally small—are numerous. There are neither asses nor mules, and sheep and cows are few. Domestic fowls are common.

Commerce.—In 1852 American diplomacy succeeded in removing the restrictions which had for centuries hampered the foreign intercourse with Japan, and many ports of the empire have since been opened to external commerce. Prior to that date the foreign commerce of Japan was limited to the Chinese and the Dutch. The Chinese trade was confined to Nagasaki, where a few junks arrived annually from the ports of Amoy, Ningpo, and Shanghai.

JAPAN

The Dutch were allowed to visit only the port of Nagasaki, where they had a factory on a small island called Desima, in which 12 or 13 merchants lived, closely watched by the Japanese, and allowed very little liberty. Two ships were annually sent from Batavia. Goods were conveyed by land on pack-horses and oxen. But the principal carriage of merchandise was by water, for though the peculiar construction of the Japanese vessels unfitted them for long sea voyages, they were well enough adapted to the navigation of lakes and rivers, and for coasting from port to port, and crossing from island to island. The rapid introduction of railways particularly throughout the main island has greatly stimulated trade and altered the old methods of communication, but the shores of the Japanese group affording great facilities for a coasting trade, from the abundance of harbors and of shelter for vessels of small size, these facilities are energetically used by the people of the coasts, who keep afloat a vast number of vessels, from fishing boats to junks of 300 tons burden. Commerce is free from any impediments by tolls or duties, and the inland trade, carried on with great activity, is promoted by great fairs, which from time to time are held at the city of Kioto. The roads are good, and kept in excellent order, and stables, taverns, and warehouses are abundant for the accommodation of merchants and other travelers. Commercial operations are conducted with promptness and regularity, and sometimes on a most extensive scale. Among the treaty ports open to foreign trade are Nagasaki, Kobé, Hakodate, Osaka, Yokohama, and Nügata. The value of the foreign trade of Japan (exclusive of Formosa) for five years is shown in the following table:

	1897	1898	1899
Imports....	\$130,755,602	\$162,319,704	\$114,529,383
Exports....	82,558,101	84,120,266	109,190,485
		1900	1901
Imports.....	\$156,679,112	\$141,117,374	
Exports.....	104,781,453	133,253,898	

The chief articles of export are silk and silk goods, coal, copper, tea, cottons, rice, matches, porcelain, mats, etc.; the chief items of import are raw and manufactured cotton, woolens, sugar, metals, machinery, petroleum, arms, vessels, etc. The commercial intercourse of Japan is mainly with the United Kingdom, the United States, China, Germany, British India, Hong Kong, Korea and Belgium, Great Britain and her colonies having the largest share, with the United States a close second. In the six months ending with June 1903, Great Britain alone, which had hitherto led in the imports into Japan, was surpassed by the United States, the imports from the latter for that period being \$12,475,246 as against \$11,901,828 from the United Kingdom. Of the treaty ports Nagasaki, Yokohama, and Kobé have by far the greatest share of the trade.

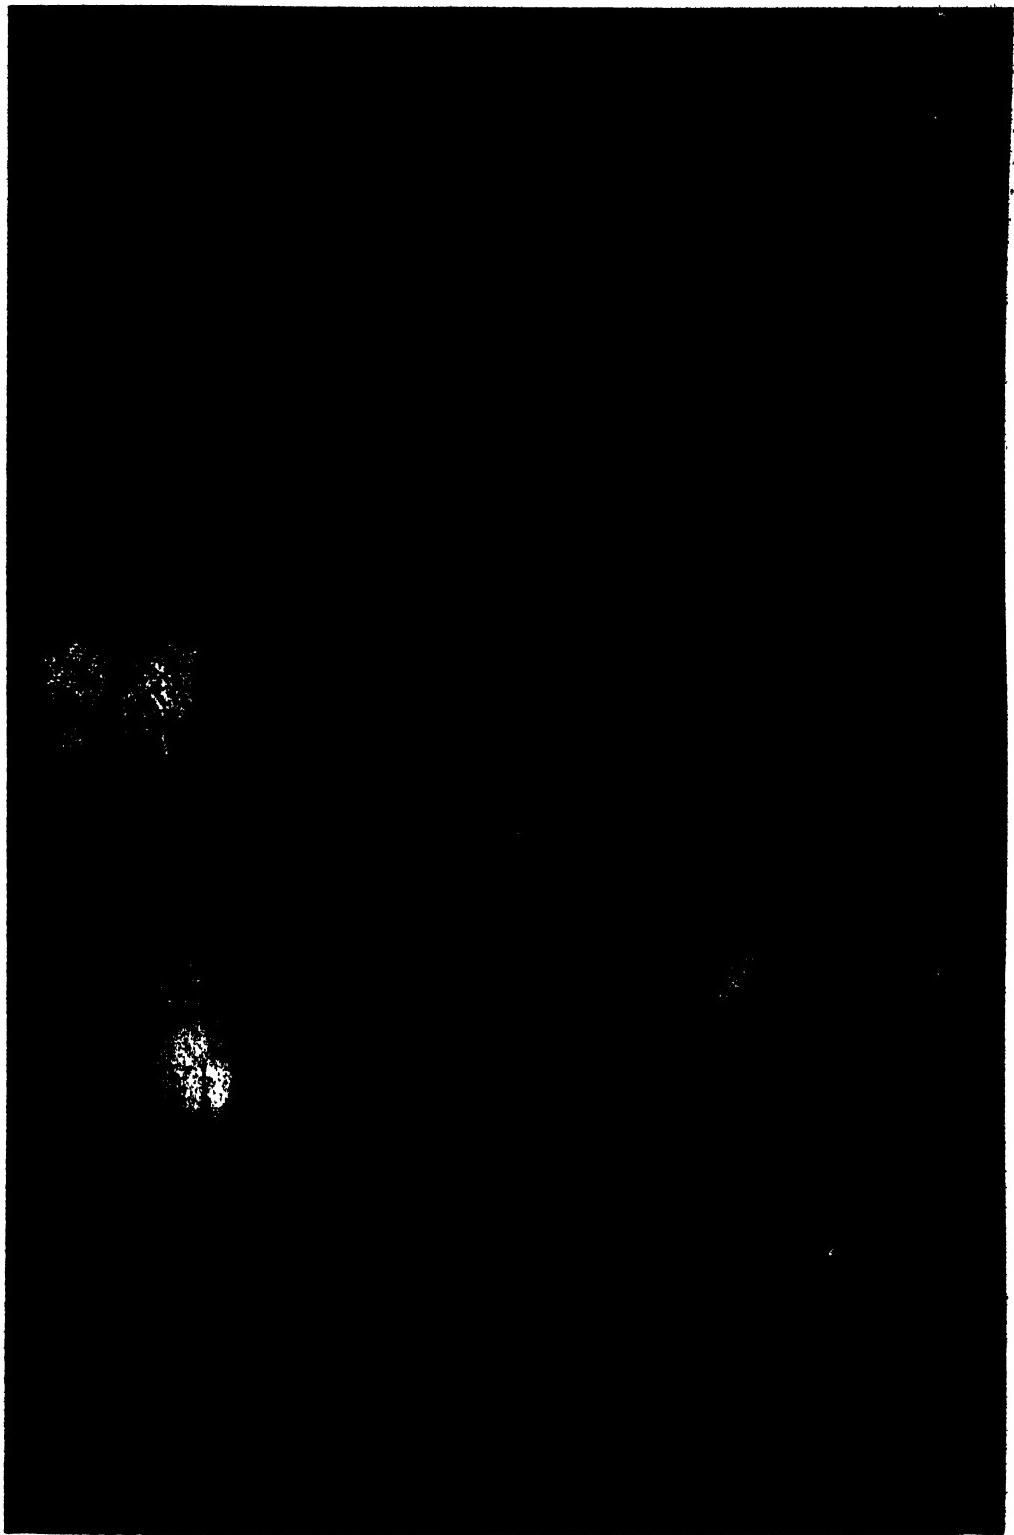

Manufactures.—The Japanese work admirably in iron, silver, gold, and all metals. Manufactures are carried on in every part of the country, and some of them are brought to such a degree of perfection as to surpass those of any other part of the world. Their lacquering in wood excels that of all other nations. They work with great skill in *sowas*, a mixture of gold and copper, which they color blue or black in a manner unknown elsewhere. Their silk and cotton goods are well made, and glass.

pottery, and porcelain in all their branches are of superior manufacture. Their steel swords are unapproachable in quality, and they make excellent mirrors of steel. Paper is made from the bark of the mulberry tree in great abundance and of remarkable strength; it is used not only for writing and printing, and for wrapping goods, but for handkerchiefs and napkins. Paper began to be used in Japan as early as the 7th century, and printing from engraved wooden blocks in the Chinese manner was introduced about 1200 A.D. Printers and booksellers are numerous, and keep the market well supplied with cheap books, many of them profusely illustrated with woodcuts. Like the Chinese, they print only on one side of the paper. Kioto is the chief seat of the book trade, and is eminently a literary city. The Japanese are skilful in carving and die-sinking, and in the casting of metal statues, which are extensively used for idols. Their iron works, tobacco factories, breweries, distilleries, and other manufacturing establishments are frequently on a large scale, employing hundreds of workmen. The cities of Kioto, Tokio, and Osaka are the great seats of manufactures. At Kioto are made damasks, satins, taffetas, and other silk fabrics of every kind, lacquered articles, caps, scarfs, screens, fans, pins, bow-strings, paints, tea boxes, grindstones, and porcelain and earthenware: at Osaka, cotton goods and iron ware; and at Tokio nearly every species of manufacture is carried on. The people show the greatest aptitude for imitating all kinds of occidental manufactures, and they are well supplied with microscopes, telescopes, clocks, watches, knives, spoons, etc., of native make from occidental models, and sold at a very cheap rate.

Modern ordnance, firearms, and ammunition, are also made in native factories, and modern shipbuilding yards for building steel and iron ships are in full operation at Osaka, Uraga, Kawasaki, and Ishikawajima.

Shipping and Navigation.—Exclusive of Formosa and the coasting trade, in 1901, 7,489 vessels, including 3,042 Japanese steamships, 1,344 Japanese junks and sailing ships, 2,998 foreign steamships and 105 foreign sailing ships, with a total tonnage of 11,051,830, entered Japanese ports; 3,064 Japanese steamships, 1,408 Japanese junks and sailing ships, 2,990 foreign steamships and 102 sailing ships, giving a total of 7,564 vessels of 11,064,951 tonnage, cleared the ports. The British ships numbered 1,644 of 4,080,538 tons: 385 were German with 1,192,153 tons; 284 were Russian with 455,243 tons, 188 were Norwegian with 240,906 tons, 175 were Americans with 407,724 tons; and 156 of 303,690 tons were French. The mercantile navy of Japan in 1901 comprised 1,321 modern steamers of 543,258 tons; 3,850 modern sailing vessels of 320,572 tons, and 911 native vessels above 200 "Koku" (about 8 tons) of 415,260 "Koku."

Railways, Roads, Posts, Telegraphs, and Telephones.—The first railroad in Japan was opened in 1872 between Tokio and Yokohama, 18 miles. In 1901 there were 4,026 miles of railroad in operation of which 1,059 were state-owned; over 2,000 miles are projected and building. There were also 227 miles of electric street railroads owned by 14 companies. The chief highways or roads comprised 4,481 miles of government roads and 15,362 miles of prefectural roads. In 1901-2 there were 5,120 post-offices through-

HIS IMPERIAL MAJESTY MUTSUHITO,
The Emperor of Japan.

JAPAN.

GATE OF THE GOLDEN TEMPLE, TOKIO.

JAPAN

out the empire handling annually a mail of 841,009,844 pieces.

In the same year there were 6,377 miles of telegraph lines and 2,087 miles of submarine cable. The number of telegrams delivered in the year was 16,713,619. The telephone service consisted of 13 exchange offices, 40 calling offices, 8,083 subscribers, and 1,562 miles of communication.

Weights, Measures, and Money.—The chief obstacle to profitable trade after the opening of the ports proved to be the peculiar ideas of the Japanese government on the subject of the currency. The money of Japan consisted of a great variety of gold, silver, and copper coins. The largest gold coin was the obang, a piece 6 inches in length and 3½ in breadth, worth about \$100. It was not in common use. The largest gold coin in ordinary circulation was the cobang, which was 2½ inches in length, 1½ in breadth, and worth about \$7.50. A still more common coin was the itzibue, which when of gold was worth intrinsically about \$1.75. The silver itzibue was the common silver coin, and worth about 20 cents. Foreign coins were not allowed to circulate, and foreigners were compelled to exchange their own money for Japanese coins, at a valuation which rendered it difficult to carry on a profitable trade. Arrangements, however, were made which remedied these difficulties, and a modern monetary law based on the metric system came into force in October 1897. The unit of value is the yen equaling 0.75 grammes of pure gold, for which however there is no corresponding coin, the former one yen silver piece having been withdrawn. The gold coins consist of 20, 10, and 5 yen pieces, the silver coins of 50, 20, and 10 sen pieces, a nickel piece of 5 sens, and bronze coins of 1 sen and 5 rin pieces. The yen is divided into a hundred sen, and the rin is the tenth part of a sen. The weights are the mommē 0.206 mommē = 1 gramme; the kin (160 mommē) = 1.325 pounds avoirdupois; and the Kwan (1,000 mommē) = 8.21 pounds avoirdupois. The measures are the shaku = .994 foot, 3.3 shaku equaling 1 metre; the Sun = 1,193 inches; the ken (6 shaku) = 5.965 feet; the chō (60 ken) = ½ mile; the ri (36 chō) = 2.44 miles; the square ri = 5.9552 square miles; the chō land measure = 2.45 acres. The liquid koku = 39,703 gallons; the dry koku = 4,9629 bushels; the liquid to = 3,9703 gallons, the dry to = 1,9851 peck.

Banking.—The principal bank of Japan is the Nippon Ginko or National bank, founded in 1882 and authorized to issue notes convertible to gold on presentation. The notes in circulation on 1 April 1902 amounted to \$93,597,168. Besides the National bank there are the Nippon Industrial bank, the Yokohama Specie bank, the Hokkaido Colonization bank, and the Taiwan bank. There are also an Agricultural-Industrial bank with 46 branch offices, a Common bank with 1,802 head offices, 1,374 branch offices, a paid up capital of \$122,579,583, and deposits amounting 31 Dec. 1900, to \$218,380,910, and savings banks with 681 head offices, 814 branch offices, a paid up capital of \$13,417,478 and deposits amounting 31 Dec. 1900, to \$14,711,530. In the post-offices which also act as savings bank 2,335,173 persons in 1900-1 deposited \$19,717,006 and withdrew \$7,350,281.

Government and Administration.—The government of Japan was, until 1889, a hereditary absolute monarchy, vested in the mikado, or emperor. This was the ancient form, but in 1585 the emperor's commander-in-chief usurped the governing power, and for nearly three centuries reduced the mikado to a secondary position. The latter resided in the royal and sacred city of Miako (or Kioto), where he was kept secluded, under the guise of a mysterious sanctity; while the shogun, living at Yeddo, exercised imperial authority, and was regarded, by foreigners at least, as a second and supreme sovereign. In 1868, however, a revolution overthrew the power and office of the shogun—he had been usually, but erroneously, called by a Chinese title, tycoon—and the mikado was restored to his ancient supremacy. In 1889 Japan received a constitution, becoming a constitutional monarchy. The mikado is sovereign of the empire, can declare war, make peace, and conclude treaties; and exercises executive powers with the advice and assistance of his cabinet, who are appointed by himself. He is also assisted by a privy-council, who give their advice in important matters when consulted. The cabinet includes the prime minister, and the statesmen at the head of the foreign office, treasury, war, navy, education, public works, etc. The legislative power is vested in the mikado and the diet or parliament, which consists of two houses, a house of peers and a house of representatives. The former consists of members of the imperial family, princes, and marquises; counts, viscounts, and barons elected by their respective orders; and a certain number of persons nominated by the emperor and by a few wealthy taxpayers, the total number being about 300. The house of representatives numbers 300; the members being elected for a period of four years, so many from each electoral district. They are paid, as are also the nominated members of the house of peers.

Finances.—The estimated revenue for 1902-3 was \$136,815,418 and the expenditure \$135,212,247. The chief items of revenue are the land tax, 2½ per cent of the market value of the land, the taxes on saké and other liquors, the tobacco monopoly, customs dues, stamp duties, income tax, and the profits on the public utilitarian services controlled by the government, telegraphs, posts, railways, mines, etc. The principal items of expenditure for 1902-3 were the army \$19,216,158, navy \$10,674,521, justice \$5,418,823, debt charges \$19,952,747, other finance \$10,929,091, etc. The receipt of the Chinese indemnity for the war of 1894-5 has been of great importance in Japanese finance. On 31 March 1900, the total public debt of Japan was \$254,232,097.

Army and Navy.—Every male Japanese of the age of 17-40 is liable to military service, and after reaching the age of 20 has to undergo three years' army training. The army on a peace footing in 1900 numbered 632,007 of all ranks, including 11,611 officers. The social position of the recruits for the army is particularly high, most of them coming from families who have a direct income of five to ten yen. Eighty per cent are sons or brothers of farmers. They are very well educated, as a rule, nearly 8 per cent being graduates of the higher common schools, 8 per cent of equivalent education (though not graduates), 25 per cent graduates of the lower

JAPAN

common schools, 16 per cent of equivalent education (though not graduates), 27 per cent (besides the foregoing) can read and do ordinary sums in arithmetic, while only 16 per cent cannot read or write.

The Japanese navy has its ministry and department of naval command in Tokio. Since 1895 the expansion of her naval resources has been such as to give Japan a fleet that is now in offensive and defensive armament, in steaming capacity, both as regards speed and distance, and in homogeneity, equal to any in the world of the same size. It comprises 7 battleships and 2 coast defense vessels, 7 first-class armored cruisers, 10 protected cruisers of the second class (with two building) 8 protected cruisers of the third class (with one building), 9 unprotected cruisers, 17 torpedo-boat destroyers and 67 torpedo-boats. Every one of these vessels is of the most modern type of naval constructive science. In 1900 Japan possessed at least four battleships of the first class, all built in England, that were protected by heavier armor over a greater extent of their side areas, and armed with a greater number of the most powerful modern guns than could at that time be paralleled in any British battleship.

The facilities for naval construction and repair possessed by Japan are also exceptional. The naval arsenal at Yokosuka, the foundations of which were laid by French engineers, has now grown to great dimensions. Cruisers of over 4,000 tons have been built in it, and, short of turning out a battleship, there is no work connected with the construction and equipment of a war vessel that cannot there be accomplished satisfactorily. The principal dock was large enough in 1899 to admit the *Victorious*, which was then one of the heaviest battleships in the British navy. Yokosuka lies inside the Gulf of Tokio, the narrow entrance to which is defended by heavy batteries, mounted both on the surrounding hills and in forts built in the gulf. There are two other fully equipped imperial dockyards. The first is situated near Hiroshima on the Inland Sea, where the principal naval college now is, and the second at Sasebo, a port approached by narrow winding channels, on the west coast of the southern island of Kiusiu. These two dockyards also are so strongly fortified as to be accounted impregnable to maritime attack.

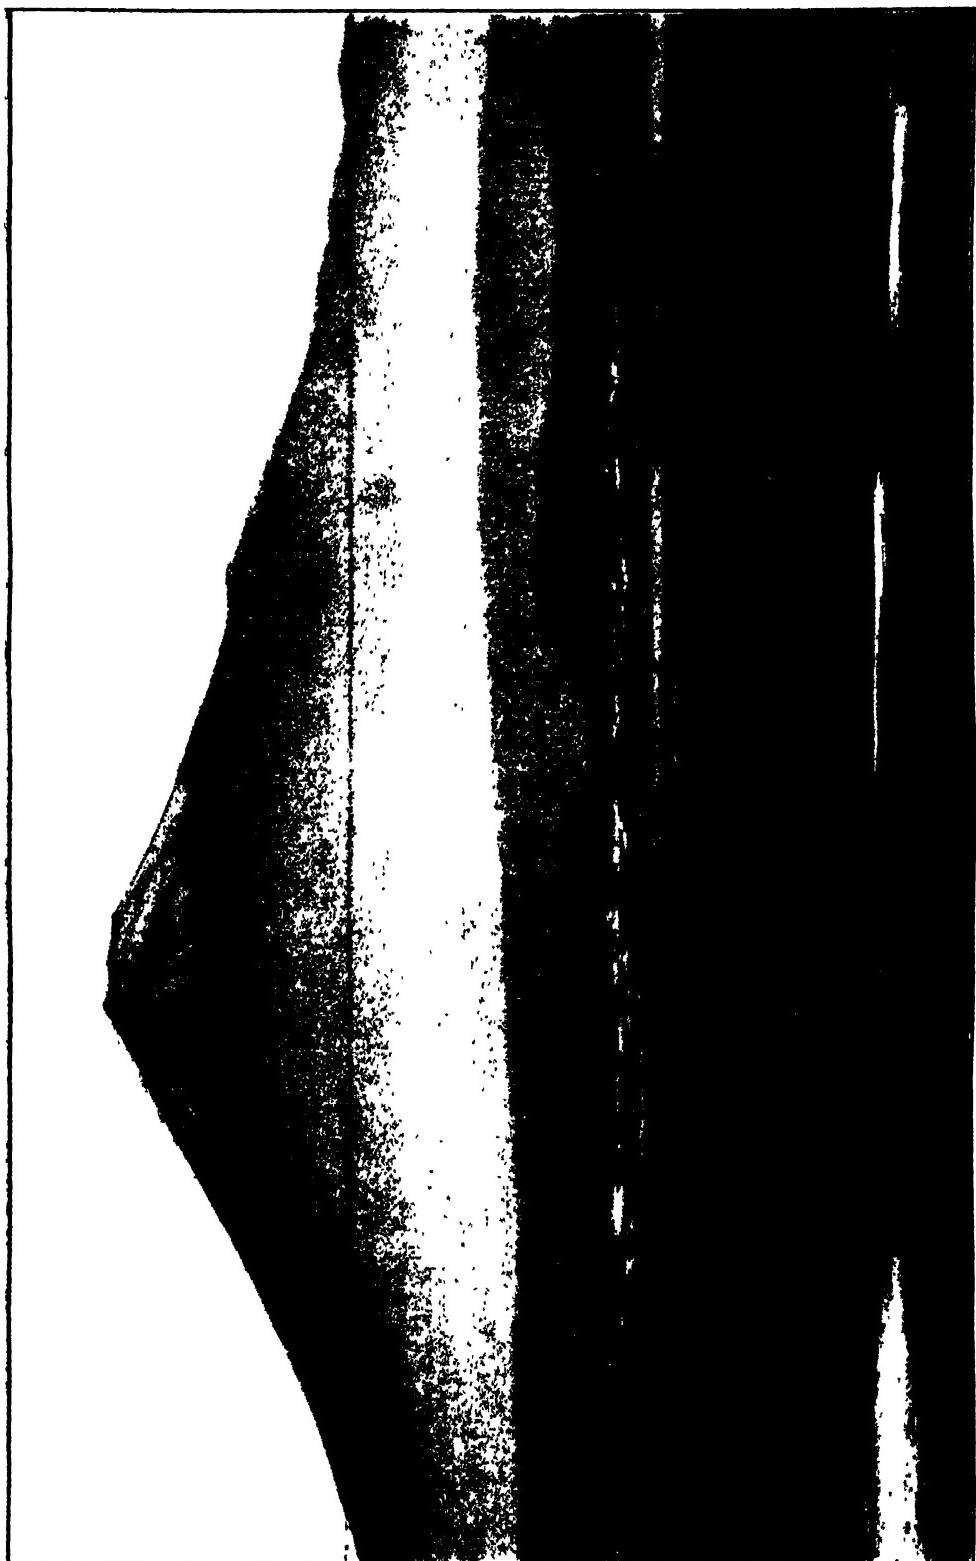

Ethnology.—The Japanese may be regarded as belonging to the great Mongolian family of peoples (apart from the Ainos of Yezo, who are of different race). They are of middling size, and generally of a yellow color, though some are brown and others nearly white. Their eyes are small, oblong, and deeply sunk in the head. Their noses are short and thick, and their hair thick, black, and glossy. The people of rank have generally fair complexions, and ladies who are not exposed to the sun have sometimes perfectly white skins and blooming cheeks. The men are vigorous and active, and the women well formed and graceful, while both sexes exhibit a higher degree of intelligence than is common among Asiatic nations. Apart from member of the imperial family, they are now divided socially into three classes: *kwasoku* or nobles, *shizoku* or knights, and *heimin* or common people; and the classes are kept distinct, with all the strictness of caste. Till 1868 feudalism prevailed in Japan, and the chief nobility

were feudal princes called *daimios*. The nobles are now divided into five ranks, corresponding with prince, marquis, count, etc. Among the chief moral characteristics of the Japanese are perseverance, courage, and frankness, with good-humor, natural politeness, and a large measure of self-confidence. The agricultural population, in particular, are distinguished for their industry, temperance, and courteous hospitality. Polygamy is not permitted, but the power of divorce on the part of the husband is limited only by the requisition that he shall provide in a suitable manner for the support of the repudiated wife; though in case she is divorced for barrenness, or for other reasons recognized by the tribunals as sufficient, she has no claim upon the husband for maintenance. Under no circumstances whatever can a wife demand to be separated from her husband. Legal concubinage was abolished in 1880. Prostitution is permitted by law, and is not deemed particularly disreputable. The courtesans or geishas are destined to their trade from infancy, and, being generally well educated and accomplished, are often selected as wives by respectable men. A singular custom among the women is that of blackening their teeth and shaving or pulling out their eyebrows when they are married. Married women also tie their girdles before, and single women behind. The Japanese of all classes are remarkably cleanly in their houses and persons. They bathe frequently, and there are many public bath-houses in the towns open to all comers for a fee generally equal to the 8th of a cent, where the sexes, prior to its legal prohibition in 1880, bathed together entirely nude, without apparently the slightest idea of impropriety.

Population.—On 31 Dec. 1899, the population of Japan amounted to 44,200,604, showing an annual increase in six years of 1.14 per cent. In 1898 the population consisted of 22,073,896 males and 21,689,257 females, divided among the various classes as follows: the 53 members of the imperial family not being included: 4,551 *kwazoku* or nobles, 2,105,608 *shizoku*, or knights; 41,648,166 common people, including 17,573 Ainos in Yezo. Also included in the population were 123,971 Japanese resident in foreign countries, of whom 90,146 were in the United States or in United States colonies. On 31 Dec. 1900, there were 12,664 foreigners in Japan, of whom 6,901 were Chinese, 2,063 English, 1,475 Americans, 554 Germans, 470 French, 176 Portuguese, 71 Dutch, 189 Russian, 89 Swiss.

Sociology.—The ordinary dress of both sexes and of all ranks is very similar in form, differing chiefly in the colors, fineness, and value of the materials, those of the higher orders being generally of silk, and of the lower orders of linen or calico. The dress consists of a number of loose, wide gowns worn over each other, with the family coat of arms woven or worked into the back and breast of the outer garment, and all fastened at the waist by a girdle. The sleeves are very long and wide, and the part of the sleeve that hangs below the arm is made to serve as a pocket. The women usually wear brighter colors than the men, and border their robes with gay embroidery or gold. Upon occasions of full dress a cloak is worn together with a sort of trousers called *hakkama*. Within doors socks are the only covering of the feet. Shoes are worn abroad, of an awk-

JAPAN

ward and inconvenient kind, consisting of soles of straw matting or of wood, which on entering a house are always taken off. Formerly they wore no hats except in rainy weather; and shaved the whole front and crown of the head, forming the rest into a tuft on the bald skull. At the present day, however, although the national costume has by no means been discarded, occidental dress is commonly worn by the upper classes on formal occasions and during the discharge of official duties; and the western method of dressing the hair is almost universally adopted. The women keep their hair very long, and usually wear on their heads numerous costly ornaments of tortoise-shell. Their dress very much resembles that of the men. They screen their faces from the sun by the fan which is carried by all classes, by ladies, priests, soldiers, and beggars. The greatest peculiarity of Japanese costume, however, is the sword, the wearing of which is a mark of rank; it is strictly prohibited to the lower orders. The middle classes carry one, and the higher ranks two swords, which are worn on the same side, one above another.

The Japanese are slaves to custom, and very strict, often oppressive, etiquette. The rules that govern social intercourse are formed into a regular system, and published in books, which are diligently studied at school. Though much has been borrowed from the Western nations in recent times, the Japanese will not be likely to give up many of their manners, customs, and ways of living, their foods and methods of cooking, their lightly-constructed houses, etc. The houses of the Japanese are low, and built of wood. The walls are coated with a cement that gives them the appearance of stone. In the windows the place of glass is supplied by very fine strong paper, which is protected from rain by external wooden shutters. Verandas encircle the houses, and to almost every dwelling, even in the cities, there is attached a garden. Store-rooms or warehouses made fire-proof by copper shutters and a thick coating of clay are numerous in the cities, where private families keep their stock of goods, and private families their valuable effects, as pictures, books, etc. Fires are frequent, and from the combustible nature of the common buildings are often terribly destructive. Conflagrations consuming thousands of houses sometimes occur. It is the custom on the completion of a new dwelling house to give a house-warming, for which purpose the neighbors and friends of the master of the new house send him liberal presents of eatables and drinkables. Tea is a universal beverage, and smoking is general among the men. In a morning call pipes and tea are served to the guests as regularly as pipes and coffee are among the Turks. At the conclusion of the visit sweetmeats are handed to the visitor on a sheet of white paper ornamented with tinsel; these are eaten with chopsticks, and if the guest does not eat the whole, he or she is expected to fold up the remainder in the paper and carry it away. At grand dinners each guest is expected to take with him a servant or two to carry off in baskets the remnants of the banquet. Fish is a general article of diet, and is varied with game, venison, poultry, and all sorts of vegetables, including a kind of sea weed. Food is eaten out of light lacquered bowls and dishes made of papier maché. Feasts

are followed by music and dancing, and are commonly closed by drinking tea and a spirit called saké. Though industrious, the Japanese are eminently a social and pleasure-seeking people, are fond of feasts and frolic, and have frequent national holidays. Music, dancing, and the theatre are favorite amusements with all classes. Mummers, mountebanks, tumblers, conjurers, and all manner of jugglers are seen in the streets of the cities, and are highly popular with the people. Their jugglers surpass those of all other countries. Among their wonderful feats is the formation from pieces of tissue paper of artificial butterflies, which, guided by the motions of a fan, fly about, advance, retreat, appear to sip the honey from flowers, and display all the airs and graces of real butterflies. The ladies of the upper classes spend much of their time in the fabrication of pretty boxes, artificial flowers, pocket-books, and purses, and in the painting of fans and pictures of birds and animals. In fine weather they join with the men in all sorts of outdoor and rural amusements, taking especial delight in fishing on the lakes and rivers, in vessels elegantly fitted up and adorned. The Japanese gentleman is invariably described as a person of pleasing address and most polished manners. Even the commonest people are neat in their persons and scrupulously observant of the forms of politeness. Suicide formerly was common by the fashionable mode of hari-kari or "happy despatch" which was generally committed by cutting open the abdomen by two gashes in the shape of a cross. It was tolerated, if not in some cases approved by the laws, and was common as a means of escaping disgrace or avenging an affront, the adversary as a point of honor being obliged to follow the example. It is now legally forbidden. There are numerous benevolent and charitable institutions throughout the empire, workhouses and foundlings established by local corporations and private persons, while the central government provides funds for sufferers from extreme calamities and grants relief to the indigent, the helpless and friendless.

Education.—Education is almost universal, the poorest and lowest laborers being taught to read and write. The women are educated with nearly as much care as the men, and there are extraordinary facilities for elementary, secondary and university instruction. During 1902-3 the percentage of children of school age receiving the prescribed course of elementary instruction was 90.35 for boys and 71.75 for girls. The total number of elementary schools was nearly 27,000. The number of teachers fell but a little short of 93,000, and the total number of children in the schools exceeded 4,683,000. The percentage of the enrolled pupils who attended daily was 84.61 per cent. The training of male and female teachers for the elementary schools receives careful attention, and the appliances and hygienic conditions of the school buildings are undergoing continual improvement.

There are seven secondary schools, in different parts of Japan, which are intended as preparatory for the universities. There are also a number of special schools in which the direct practical applications of the subjects studied are kept in view. In the Tokio Foreign Languages School, English, French, German, Russian, Ital-

JAPAN

ian, Spanish, Chinese and Korean are taught. The Tokio Fine Arts School provides five courses of study, including painting, designing, sculpture, architecture and industrial fine arts. The Tokio Academy of Music furnishes complete instruction in both Japanese and foreign music. There are technical schools intended to prepare men to take charge of industrial operations. The agricultural school at Supporo trains agriculturists for the island of Yezo, which is to Japan what Alaska is to the United States. The Tokio Technical School trains managers and foremen of factories, and a similar institution, already fully equipped, has been started in Osaka. Even the commercial aspect of education is not overlooked; the higher commercial school in Tokio has 53 instructors and 666 pupils.

There are in Japan two universities, the Imperial University of Tokio and the Imperial University of Kioto. The former comprises a University Hall and six colleges of law, medicine, engineering, literature, science and agriculture. The college of engineering offers nine courses: civil engineering, mechanical engineering, electrical engineering, naval architecture, technology of arms, civil architecture, applied chemistry, technology of explosives, and mining and metallurgy. In 1903 the total number of resident instructors was 222, and there were 35 assistant professors now studying in foreign countries. The students numbered 2,880, and included eleven foreigners, one of them a native of the United States. The University of Kioto, though founded much later than that of Tokio, includes, besides the University Hall, colleges of law, of medicine, and of science and engineering. The college of science and engineering provides courses in mathematics, physics, pure chemistry, chemical technology, civil, mechanical and electrical engineering, and mining and metallurgy. In 1903 there were 25 professors and 186 students.

There are laboratories for special purposes and many public libraries, and the combination of educational forces exhibits the astonishing progress in education made by Japan within 30 years.

Religion.—The chief religion is that of Buddha, which is, however, exotic and comparatively modern. Another and older faith exists, called Shinto or Shin-Syu. The word *shinto* is equivalent to spirit worship. The Shinto belief supposes the existence of an infinite number of spirits, exercising an influence over the affairs of the world, who are to be propitiated by prayers and the observance of certain rules of conduct, by cleanliness of person, and purity and cheerfulness of heart. The chief of these spirits is the sun, and after him the elements. These are called *Dai Zin*, "great spirits." The inferior spirits, who are very numerous, are chiefly heroes canonized for their worthy deeds or illustrious qualities. The most prominent and popular of these minor deities is *Fatsman*, the god of war, who is an apotheosis of the 16th emperor of Japan. He is supposed to have been born in a supernatural manner, and is universally honored throughout the empire. Although there are a large number of nominal Christians in Japan, it is not believed that Christianity has made many real converts, motives of self-interest — such as the obtaining of a free western edu-

cation in the mission schools — often underlying so-called conversions to the Christian faith. There are no fewer than 12 sects of Buddhists with 32 creeds. Freedom of religious belief and practice when not prejudicial to peace and order is ensured by the constitution.

Judiciary.—A modern system of justice comprising four classes of courts has been established. Throughout the empire (exclusive of Formosa) there are 302 subdistrict courts for all petty, civil, and criminal cases; 49 district courts exercising a more extensive jurisdiction in civil and criminal cases, and a revising jurisdiction over the subdistrict courts; seven courts of appeal from the decisions of the district courts; and one court of cassation in Tokio, the supreme court exercising an appellate jurisdiction over the courts of appeal, and an original jurisdiction in serious crimes against the imperial house and state, and in serious charges against members of the imperial family. Seven judges preside in the court of cassation; five judges in the courts of appeal; three judges in the district courts, one being chief judge, and one judge in the subdistrict courts. A court under the direct supervision of the emperor deals with disputes respecting administrative affairs.

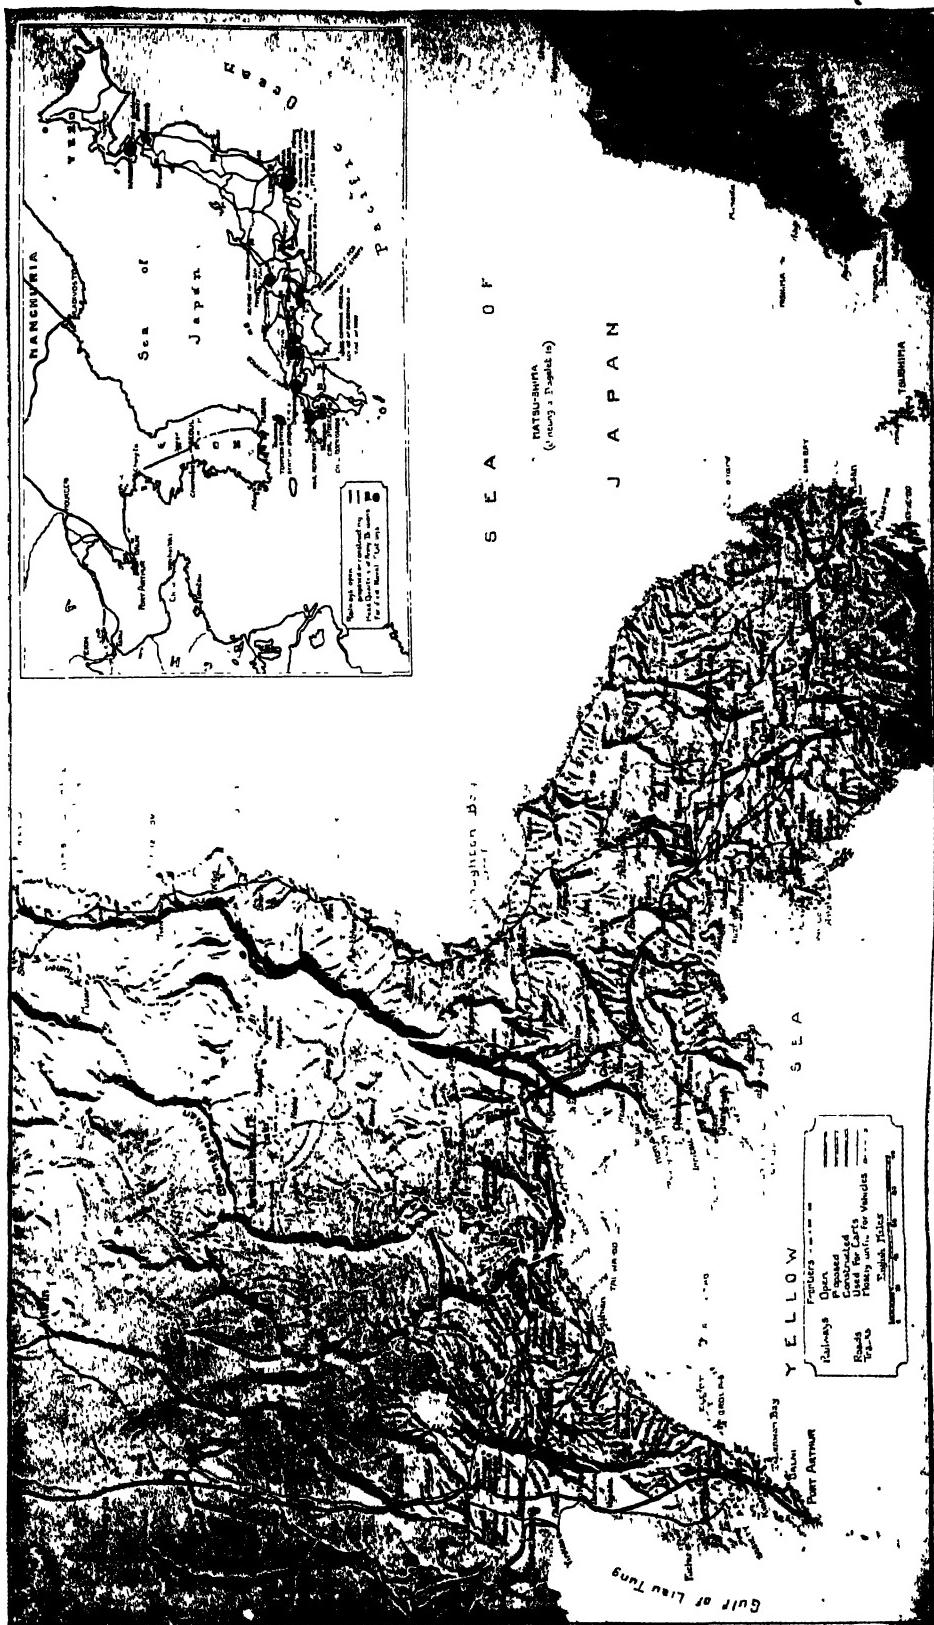

Local Government.—In 1876 a new division of the empire into districts or prefectures for local government was made, namely, 43 *ken* or rural districts, and 3 *fu* or residential districts: Tokio (Yeddo), Osaka, and Kioto. The prefectures are subdivided into *shi* = municipalities, and *gun* = counties; the counties are again subdivided into *cho* = towns, and *son* = villages. The units of local government are village, town and municipality, forming local corporations of the same name; supervising all are the prefectoral governor, assembly and council. Citizenship and electoral qualifications are conferred on all male Japanese not less than 25 years of age who for two years reside in a municipality, town, or village, share its burden, and pay land tax or not less than \$1 direct national tax annually.

History.—The history of Japan, like that of other ancient nations, begins with a mythical period, during which gods and goddesses mingled openly in the affairs of men. The authentic annals of the country commence with the reign of Sin Mu, who was at the same time high priest and emperor, about 660 B.C. He is said to have civilized the people, and to have established laws and a settled government. For many centuries his posterity reigned on the throne he had founded, bearing the title of mikado, and claiming to rule by divine right and inheritance. They were worshipped as gods upon earth, and long exercised the most absolute power. Women were not excluded from the succession, and in ancient Japanese history there are many famous empresses. The most celebrated of these was the Empress Singokogu, who began her reign in the 3d century of the Christian era. She conquered Korea, and gave birth to a son who succeeded her. He was so successful and renowned that at his death he was deified, and is now the Japanese god of war. In this early period a free intercourse appears to have been carried on with China, from which country about the middle of the 6th century Buddhism entered Japan, and was extensively spread among the people. Toward the end of the 7th century the claims of two

JAPAN

brothers to the throne led to a great civil war, which was ended by the defeat and suicide of the younger. About the end of the 8th century a foreign people of whom nothing more is known than that they were not Chinese, but natives of some more distant country, invaded Japan, and being constantly reenforced from home, maintained hostilities for 18 years before they were entirely expelled. Between the 9th and 12th centuries several new religions were introduced by foreign priests or by Japanese returning from foreign countries. The reign of the emperor Itsu Sio (987-1012) was remarkable for a great epidemic over the whole country, and for the number of learned men who adorned the court. In the reign of Go Rei Sen (1046-69) a great rebellion took place in the province of Osiu, which lasted for five years, and is much celebrated in Japanese literature. Another famous rebellion was headed by Kyomori, a prince of the blood, in the reign of To Ba (1108-24). About the middle of the 12th century, during the reign of the Emperor Kon Yei, the authority of the mikado began to decline. The vassal princes took advantage of the weakness of the imperial government to strengthen their own power, and great confusion ensued. To remedy these evils, the court of the mikado created the office of shogun or commander-in-chief of the army, and appointed to the post Yoritomo, one of the most celebrated characters in Japanese history. He was a young soldier of high birth, related to the imperial family, and was successful and ambitious, so that after quelling the turbulence of the great vassals and restoring the authority of the crown, he contrived to concentrate in his own hands the real power of the government, without, however, depriving the mikado of his nominal rank, dignity, and religious supremacy. The office of shogun was made hereditary in the family of Yoritomo, whose descendants became in fact joint emperors with the mikado. The Mongols having invaded China in 1260 and conquered the greatest part of it, their leader Kublai Khan sent envoys to Japan in 1268, and again in 1271 and 1273, summoning the Japanese government to enter into an alliance with him. The Japanese dismissed the envoys without any answer. The Mongol conqueror, irritated at their insulting indifference to his proposals, sent against them a great fleet and army in 1274, or according to Marco Polo in 1264. This expedition landed in Japan, but was defeated and the army cut to pieces. A still greater expedition was despatched in 1281, and met a similar end, the Japanese sparing only three of the invaders to carry back to China the news of the fate of the rest. Japan from that time to the present has not been molested by invaders. In the 16th century civil wars broke out, and a revolution took place, by which Faxiba, a man of extraordinary ability and energy, originally a private soldier, was raised to the supreme command, and became shogun, under the name of Taiko Sama or Lord Taiko, with the additional title of tycoon, which is now the appellation commonly given to the emperor at Yedo, or lay emperor. He was the first secular monarch who assumed entirely the absolute control of the empire, some share in the government having been hitherto granted to the mikado, who was now reduced to the condition of a merely nominal monarch. Taiko Sama is regarded by the

Japanese as the greatest character in their history, at least since the mythical period, and was eminent not only as a warrior and statesman, but as a legislator. His laws and policy until modern times were observed by the government of Japan, and secured to the nation an almost unequalled permanence of peace and prosperity. The turbulence of the vassal princes, who were then only 60 in number, and were individually powerful, was the chief source of the troubles that had afflicted the empire, and Taiko Sama took the decisive step of reducing their forces by dividing each principality into several. This policy, steadfastly carried out by him and his successors, resulted in establishing 604 distinct principalities and lordships, none of which was of sufficient magnitude to be formidable to the imperial power. It was during the confusion that preceded the rise of Taiko Sama that the Europeans began to be connected with the affairs of Japan. The existence of that empire was first made known to Europeans by Marco Polo, who in his narrative, written about 1298, mentions it under the name of Zipangu, a modification of the Shien-kuo of the Chinese, from whom he had obtained his information. He says: "Its inhabitants have fair complexions, are well made, and are civilized in their manners. Their religion is the worship of idols. They are independent of any foreign power, and governed only by their own kings. They have gold in the greatest abundance, its sources being inexhaustible; but as the king does not allow of its being exported, few merchants visit the country, nor is it frequented by much shipping from other parts." The Portuguese, after Vasco da Gama had doubled the cape of Good Hope in 1497, rapidly extended their discoveries and conquests in southern Asia. In 1542, three Portuguese sailors, who had deserted their ship and taken possession of a Chinese junk, were driven by storms upon the coast of Japan, and to them is ascribed its European discovery. About three years later a Portuguese adventurer, Fernam Mendez Pinto, while cruising with some companions of his own nation in the vessel of a Chinese pirate, was driven by foul weather into a harbor in one of the smaller Japan islands. He was well received, and carried back to the Portuguese settlements in China such a report of the riches and magnificence of Japan that great numbers of traders and adventurers flocked thither, and an active commerce soon sprang up. Missionaries speedily followed the merchants, and in 1549 Japan was visited by the celebrated "Apostle of the Indies," St. Francis Xavier. Both merchants and missionaries were favorably received, and while the one class found a ready and most profitable market for their goods, the other rapidly converted vast numbers of the natives to Christianity. Three of the most powerful of the Japanese nobles, the princes of Bungo, Avima, and Omura, were among the converts. In 1582 the Japanese Christians sent an embassy with letters and presents to Rome to do honor to the Pope, and assure him of their submission to the church. In the two years which followed their return (1591-2) it is said that 12,000 Japanese were converted and baptized. Tempted by the success of the Portuguese, the Dutch East India company in 1598 despatched five merchant vessels to Japan, one of which reached it in 1600. In 1609 other Dutch ships

JAPAN

arrived, and were well received by the Japanese, who conceded to them the port of Firando for a factory or settlement, with considerable privileges. Before the arrival of the Dutch, who were then at war with Portugal, the Japanese government had become distrustful of the Portuguese, whose astonishing success made them haughty and disdainful of the feelings and prejudices of the natives. Portugal was at that time united with Spain, and a Spaniard, when asked by Taiko Sama: "How is it that your king has managed to possess himself of half of the world?" indiscreetly answered: "He sends priests to win the people; his troops then are sent to join the native Christians, and the conquest is easy." This answer, it is said, made a deep impression on the Japanese government. In 1587 Taiko issued an edict for the banishment of the missionaries; the edict was renewed by his successor in 1596, and in 1597 23 priests were put to death in one day at Nagasaki. The Christians on their part took no measures to pacify the government, but defied it, and began to overthrow idols and pull down heathen temples. This led to dreadful persecutions in 1612 and 1614 when many of the Japanese converts were put to death, their churches and schools destroyed, and their faith declared infamous and rebellious. The Portuguese traders were no longer allowed free access to the country, but were confined to the island of Desima at Nagasaki. In 1622 a frightful massacre of native Christians took place in the neighborhood of Nagasaki, and horrible tortures endured with heroic constancy were inflicted on multitudes in the vain effort to make them recant. In 1637 it was discovered by the Japanese government that the native Christians, driven to despair by persecution, had entered into a conspiracy with the Portuguese and Spaniards to overthrow the imperial throne. The persecutions were renewed with increased rigor. Edicts were issued banishing the Portuguese forever from Japan, and prohibiting any Japanese, or any Japanese ship or boat, from quitting the country under the severest penalties. By the close of 1639 the Portuguese were entirely expelled, and their trade transferred to the Dutch, who, as enemies to the Portuguese and to the Roman Catholic faith, were not involved by the Japanese in their condemnation. In 1640 the oppressed native Christians rose in open rebellion in the province of Simabara. They seized a fortified place, made a long and gallant stand against the imperial troops, and were at length subdued only by the artillery and military science of the Dutch, who were either persuaded or compelled by the Japanese to cooperate against the rebels. The Christian stronghold was finally carried by storm, and all within its walls, men, women, and children, to the number of many thousands, put to death. In the next year the Dutch were ordered to quit their factory at Firando, and take up their residence, under very rigid inspection, in the island of Desima at Nagasaki. There they remained for more than two centuries in undisturbed monopoly of the entire European trade of Japan, notwithstanding occasional efforts of the Russians and English to obtain intercourse with the secluded empire. These efforts were resolutely repulsed, and led in one case to the imprisonment for two years in Japan of the Russian Captain Golownin and several of his companions. In 1852 the United

States government, in consequence of complaints made to it that American seamen wrecked on the coast of Japan had been harshly treated by the authorities of that country, despatched an expedition under the command of Commodore M. C. Perry, who was instructed to demand protection for American seamen and ships wrecked on the coast, and to negotiate if possible a treaty by which American vessels should be allowed to enter one or more ports to obtain supplies and for purposes of trade. In February 1854, Commodore Perry, with a squadron of seven ships of war, entered the bay of Yedo and came to anchor within a few miles of that capital. During the previous year he had entered the same bay and delivered to the Japanese a letter to the emperor from the President of the United States. On 31 March 1854, after much difficult negotiation, a treaty was agreed upon, dated at Kanagawa, the nearest large town, though really signed at the village of Yokohama. By this treaty the ports of Simoda and Hakodadi were appointed for the reception of American ships, where they can be supplied with wood, water, provision, coal, and other requisite articles, and protection and assistance were guaranteed to shipwrecked seamen. Liberty to trade under certain restrictions was also granted, and an arrangement made for the residence of American consuls at Simoda and Hakodadi. In September 1854, a British squadron commanded by Rear-Admiral Sir James Stirling entered the harbor of Nagasaki, and a treaty was soon concluded between Great Britain and Japan, by which Nagasaki and Hakodadi were opened to foreign commerce. Subsequently the Russians made a similar treaty and obtained equal privileges; and by a treaty dated 9 Nov. 1855, the Dutch in Japan were relieved from most of the restrictions so long imposed upon them at Desima. On 17 June 1857, a new treaty was negotiated at Simoda with the Japanese government on behalf of the United States by Mr. Townsend Harris, United States consul-general for Japan, by which the port of Nagasaki, in addition to those of Simoda and Hakodadi, was opened to American trade, and additional privileges granted to American merchants. In 1858 Mr. Harris succeeded in reaching Yedo, where he concluded a still more favorable treaty. In the same year a British squadron conveyed a British ambassador, the earl of Elgin, to Yedo, where, on August 26, a new treaty was concluded between Great Britain and Japan, by which the ports of Hakodadi, Kanagawa, and Nagasaki were opened to British subjects after 1 July 1859, Nee-e-gata or some other convenient port on the west coast of Nippon after 1 Jan. 1860, and Hiogo after 1 Jan. 1863, and various commercial privileges granted to British merchants. In 1860 a Japanese embassy visited the United States, and in 1861 an embassy was sent to the European courts. The rebellion of 1868 already referred to under the paragraph *Government*, followed on the deposition of the shogun, and the reform movement for modernizing Japanese institutions organized by Iwakura, Okubo, Saigo, and Kido.

This progressive movement was chiefly, if not solely, the result of political foresight. The Japanese at heart are as anti-foreign as their Chinese neighbors; but, unlike the latter, they grasped the fact that western encroachment could only be checked by western methods.

JAPAN.

LIEUT. BENT IN THE MISSISSIPPI'S CRUISER PASSING THROUGH A FLEET OF JAPANESE BOATS.

JAPAN

When the progressive and sagacious statesmen of Japan perceived that their existence as a nation depended upon meeting the great powers of the West on their own ground, they determined upon a thorough and comprehensive metamorphosis. Not only was the youth of Japan sent to Europe for the purpose of acquiring western sciences, but foreign advisers were called in wholesale to reorganize the army and to instruct the nation in the ways of the West. The first innovation was the construction of a railway in 1869, and since that date an immense railway system has been developed, chiefly for strategical purposes, and latterly with but little assistance from foreign engineers.

The building up of a powerful and efficient navy was one of the first considerations of the Japanese government; and not contented with merely organizing a fleet, they prepared for the chronic industrial warfare, which is the inevitable condition of modern life, by subsidizing the construction and the maintenance of a mercantile marine. Determined to make themselves independent of Europe and America, the Japanese established dockyards and arsenals, at which modern ships and armaments are now turned out under foreign supervision, and frequently by native engineers unaided by Europeans. Although the workmanship attained in the latter case is not, generally speaking, on a level with that of the West, it is admitted that the Japanese are making rapid progress in engineering and ship-building. The problem of education received the early attention of Japanese reformers. Commissioners were despatched to Europe in 1871 charged with the task of mastering the essential points of Western education. On their report an educational code, which has since been frequently revised, was drawn up. The new conditions of life necessitated the abolition of Japan's traditional code of laws, which she proceeded to replace with a legal code borrowed from the West; and to these laws foreigners in Japan since the nullification of extra-territoriality in 1899, are now obliged to submit themselves. Although the native industries may be said to die hard in Japan, the country has undergone during the last few years little short of an industrial revolution. In 1897 Japan adopted a gold currency, and placed herself thereby on a financial level with the civilized powers of the West. Side by side with the modern development of their country the Japanese have preserved a remarkable spirit of patriotism. These reforms were not effected without considerable opposition and several risings of the nobles, who, in consequence of the revolution of 1868, were deprived of their privileges, and to a large extent of their incomes, took place. That of 1876-7, headed by the reformer Saigo, taxed the resources of the government pretty severely before it was quelled. In 1894 war with China broke out, ostensibly owing to disturbances in Korea, over which both China and Japan had long claimed a suzerainty, and which had been a frequent source of friction between the two countries on former occasions. Active hostilities began in Korea, from which the Japanese gradually drove out the Chinese troops. A great naval engagement took place off the mouth of the Yalu River, which separates Korea from China, and the result was entirely in favor of the Japanese, who then pushed their way into

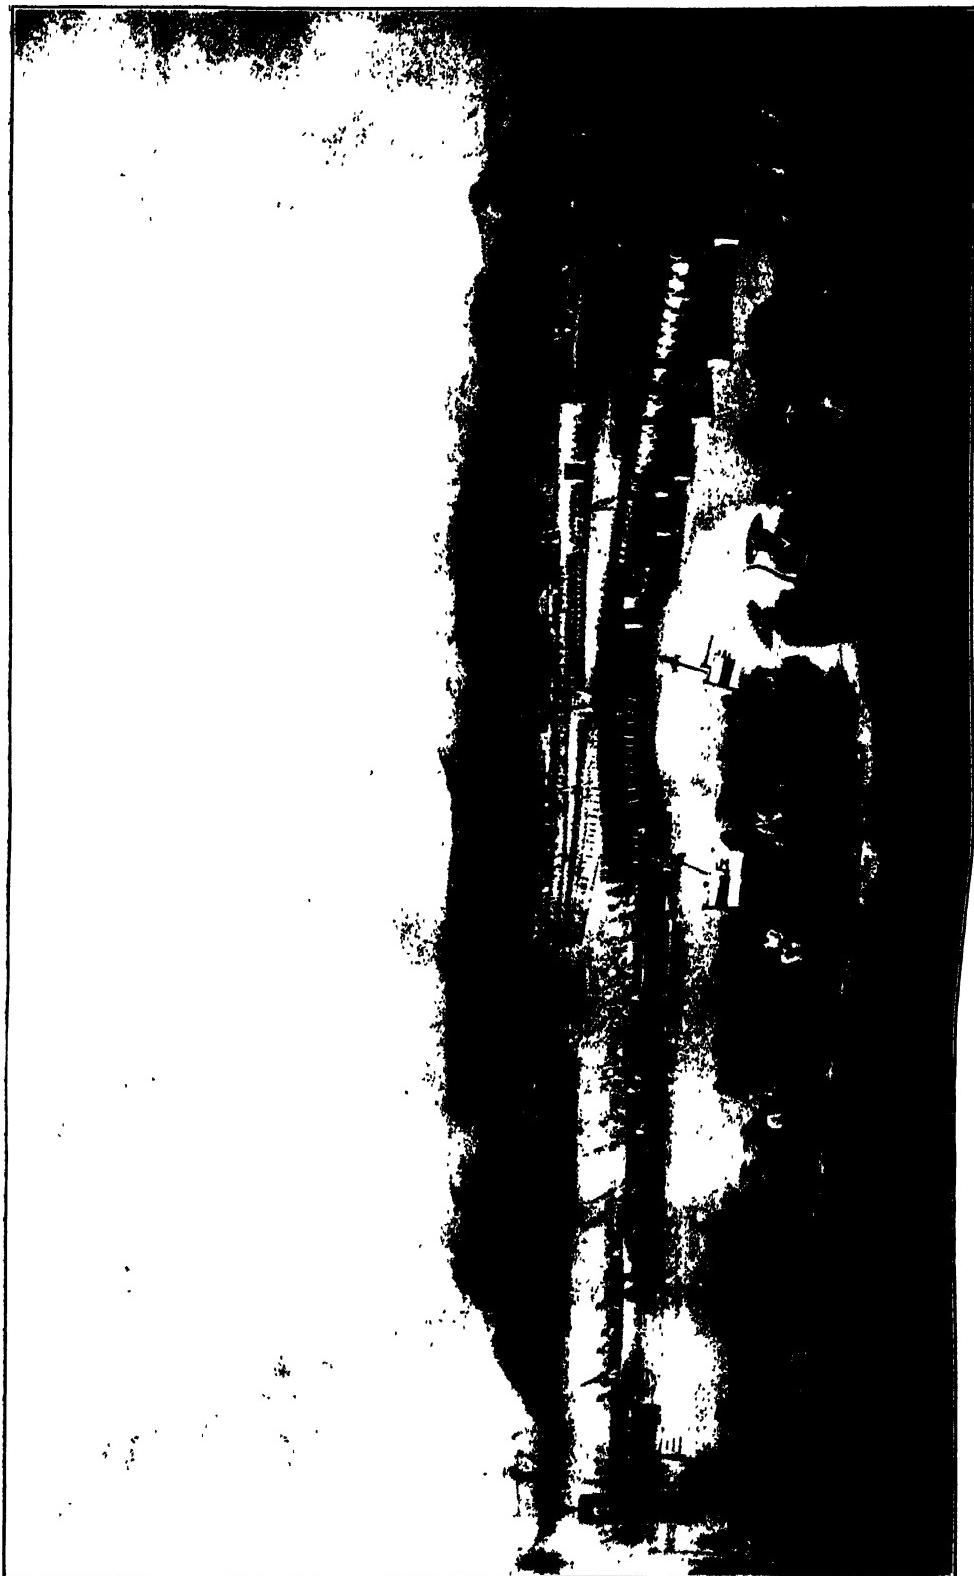

Manchuria, driving the Chinese before them. Further great successes were the capture of the Chinese fortified port and arsenal of Port Arthur, at the entrance of the Gulf of Pe-chee-le of New-chwang, Wei-hai-wei, and great part of the Chinese fleet. China then saw that it was hopeless to continue the struggle, and in March 1895, Li Hung Chang was sent to Shimonoseki to sue for peace. Japan demanded, in addition to a heavy war indemnity, the cession of the Liao-tung peninsula. To these terms China's plenipotentiary ostensibly agreed, but it had been secretly arranged that Russia should step in and forbid the alienation of territory on the mainland. Accordingly Japan found her demands opposed by Russia, France, and Germany, and was compelled to forego the legitimate fruits of her victory. There is no doubt that Japan's primary object in making war was to check the advance of Russia to a threatening position on the mainland of Korea. Her statesmen hoped, by the insistence on Western reform, to make Korea a powerful buffer state between their own country and Muscovite aggression; and since the conclusion of the war there has been a constant—and singularly even—struggle of diplomacy between Japan and Russia for paramount influence in Korea. Instead of the Liao-tung peninsula, the island of Formosa and the Pescadores Islands were ceded to Japan, who was thus obliged to relinquish her design of thwarting Russia's objects in Northern China. A subject which constantly occupied the attention of Japanese statesmen during the 12 years that preceded the war with China was treaty revision. Japan had sacrificed national pride in order to place herself upon an equality with the West, her progress had been serious and genuine, and her statesmen protested against the continuation of extra-territorial privileges which relegated the country to the level of barbarous and uncivilized states. Great Britain was the first power to acknowledge Japan's claims to equality, and in July 1894, a new treaty, which was not to take effect for five years, was concluded by the two governments. Other powers followed suit, and on 17 July 1899, Japan attained her international majority, and will henceforth be treated on an equal footing with the Christian nations of the West. The principal effect of treaty revision has been to abolish extra-territoriality, and to throw open the whole of Japan to the foreigners for purposes of travel, trade, or residence. Whether the fears of the foreign merchants at the treaty ports will prove justifiable remains to be seen; but the fact must not be overlooked that the laws of Japan are founded upon the best codes of civilized countries, and that the future of the Japanese nation is largely dependent, at any rate for the present, upon their cultivating friendly relations with the great powers of the West.

Language and Literature.—Though the Japanese language is grammatically analogous both to those of the Mongolo-Tartaric and Manchu-Tungusic families, it differs radically from them. The Japanese language is not monosyllabic (like Chinese), but agglutinate, and has an alphabet of 47 letters, which are written in two different forms, one rendered complex by the addition of variations, known as the Fira-Kana form of character; and the other, the Kata-Kana character, entirely without variations, and consequently much simpler. Its claim to be akin to

the Chinese is invalidated by the essential characteristics of the Nipponese tongue, which differs from the Chinese as to the etymic import of its elements and in its polysyllabism. The genuine portion of the former is called *Yomi*, while the Chinese supererogation goes under the name of *Koye*. Siebold endeavors to establish genetic connections of the Japanese with various other languages, as for instance with that of the Ainos inhabiting the northern part of the island of Yezo and the southern point of Saghalien (Tarakai); with that in Santam on the coast of Manchuria, south of the Amoor; with those of the Incas of Peru and the Bochicas of New Granada; with that of the Muiscas of Brazil, etc. Although the Korean languages have many features in common with the Japanese, their divergence is radical. The area of the Japanese comprehends the three great islands with some parts of Yezo and other southern Kuriles, of South Saghalien, and also the Loo Choo group of islands, where a dialect or closely related language is spoken. The vernacular idiom differs remarkably from the written, by peculiar terminations, particles, and construction. The written language has also a peculiar style, named *naiden*, for religious and mystical subjects, and another, called *gheden*, for profane composition. There are also two styles of allocution, the one of etiquette, the other vulgar. The speech of women also differs in some particulars from that of men. The *Yomi* is sonorous, soft, and agreeable; almost all words end in vowels, which, however, are often dropped, and in *m* and *n*. Some sounds are of difficult pronunciation to us. A too soft utterance of consonants produces vagueness between the sounds of *p*, *b*, *f*, and *v*; between *s* and the English *z*, *sh* and the French *j*. Although there are no decided *k* and *l*, some Europeans fancy they hear them, while better phonetic authorities credibly assert that they are really *f* and *r* respectively. The initial *r* sounds almost like *dr*. The number of original vocabularies is inconsiderable. Technical terms are generally Chinese, and often much altered. There are two graphic systems. (1) Sinography, somewhat modified. At the request of Ozinteno, the 16th Dairi, Kieu-su-wang (Jap. Kosovo), king of Pe-tsi (Takusai, in Korea), sent Wang-jin (Jap. Vonin), in 285 A.D., to Japan to introduce there the *Tshin-tsé* (Jap. *Sinzi*, China letters), which were afterward named *Han-tsé* (Jap. Kanzi). From that time both the *Tshin-tsé* and the Chinese language became common in Japan; although the former are peculiarly pronounced, as may be seen in the examples within parentheses below. This divergence is, however, scarcely greater than that of the Chinese dialects from the Mandarin idiom. The sinograms of the learned are called *Taf* and *Sso*. With the varieties of sounds there are about 380 Japanized sinograms, beside the unaltered *Tshin-tsé*. The former are explained by the *Kata-kana* (see below); thus: *kekko*, beautiful, by the Jap. *birei*; *mei-fit* (celebrated pencil), fine writing, by *nō-zio*, etc. Sinograms are sometimes pronounced very differently from their proper sounds; thus: *ye* (the 27th Chinese syllable), river, from the sinographic *sin-kiang*; *me* (17th Chinese syllable), woman, sinogr. *nii*. Synonyms are often written with the same sinograms. Prefaces of books are commonly written in sinograms. (2) As these did not

altogether suit the peculiarities of Japanese phonism and grammar, Kibi or Kibi-ko (733), who had been educated in China, selected 47 sinograms, and simplified them into syllabic signs, in analogy with their original sounds. This syllabary was named *I-ro-fa*, from the first 3 syllables, just as our alphabet is named from the first two letters. This Irofa, surnamed *Kata-kana* (half letters or signs), is used collaterally with sinograms, explaining their sounds, and serving beside for the indication of grammatical particles; in the same manner as the Manchu interlinear or marginal letters serve in Chinese texts. This form is called sometimes the writing of men. The 2d Irofa, surnamed *Fira-kana* (expanded letters), was contrived by the celebrated bonzes Comiu and Kobo (774-835), and became so manifold by the licenses of the pencil as to be almost illegible, especially owing to additions by a third bonze, Kiakuso, who added a 48th sign for a nasal sound. This is the cursive writing for daily transactions, sometimes called the writing of women. The 3d Irofa is *Mun-yo-kana* (myriad-leaves-letters, so called from the poem *Mun-yo-sio* by Tatsi-bana-no Moroye, about the middle of the 8th century, containing 10,000 verses), and is almost a sinogrammatic prototype of all the Irofas. The 4th is the *Yamato-kana*, a simple cursive script, which is used promiscuously with all the others. The original idea of the Irofa is Buddhistic and Indian. The varieties of form in all the Irofas are a great impediment to expeditious reading, the difficulty of which is increased by the many ligatures between the letters. Writing and reading proceed in vertical columns downward and from right to left. There are also some other diacritic as well as punctuating signs. The former are two, namely: the *nigori*, which is almost like our quotation mark (""), and indicates that the hard or rough sound of a letter is modified, so as to cause the *ko*, *fo*, *to*, etc., to be pronounced *go*, *bo*, *do*; and the *maru* (°), which indicates tenuification, or hardening, for instance of *fo* into *po*. The marks of punctuation denote also the transposition, repetition, etc., of syllables; they also separate sinograms from Irofas. The order of syllables is as follows: *i*, *ro*, *fa*, *ni*, *fo*, *fe*, *to*, and so on, without any symmetry or analogy. Properly classed, they are: the 5 Latin vowels, *a*, *e*, *i*, *o*, *u*; the labial *f* with these vowels suffixed (*fa*, *fe*, *fi*, *fo*, *fu*); the guttural *k* with the same; the *m* with them; then the *s* with them (and modified by diacritics into *z*, French *j*, Eng. *sh*); then *y*, *t*, *r*, *n*, all with those vowels attached; lastly, two more, *n'a*, *n'e*. The *t* is sometimes *ts*, *dz*, etc. The transcription by Europeans is variable. There is, beside, a kind of metaphor, by which *fō* becomes *fau* and *fafu*; *riō*, *riyau*; *kvo*, *kavau*, *kafau*, etc. This is similar to the Latin *lavō*, *lavatūm* and *lautūm*, *lotūm*; *faveo*, *fautūm*, *fatūm*, *fætus*, etc. Dialectic variations depend chiefly on modifications of sounds; in Yedo, for instance, *r* predominates; elsewhere *f* is pronounced *v*; *fu* like *u*, etc. In the grammar, there is no gender; the male sex is indicated by *vo*, the female by *me*. Substantives do not differ on the whole from adjectives. The latter are often replaced by qualitative verbs or by the particle of the genitive, and are euphonically varied, according to their position; thus, for instance; *akae fana*, red flower; *akashe fanava*,

JAPAN.

FIRST LANDING OF AMERICANS IN JAPAN, JULY 14, 1853.

JAPAN

red is flower-the; *akovo naru*, red becomes it (as in Magyar *vörössé less*); *aka irono fana*, Lat. *rubri coloris flos*. There is no proper article, but the suffix *va* sometimes determines the acceptation, or shows the French *partitif*; and *sya* signifies "as regards." Cases are indicated by suffixes, as in the following example: *sten*, or *sten-va*, Lat. *cælum*; *sten-no* (oftener *sten-ga*, as in Korean), *cæli*, *sten-ni*, *cælo*, *versus*, and *ad cælum*; *sten-ye*, *in cælum*; *sten-vo*, *cælum*, accusative (also *sten-woba*); *sten-de*, *cælo*, ablative; *sten-yori*, *ex cælo*; *sten-kara*, *de cælo*, per *cælum*, etc. The plural is formed by suffixes, as *tatsi*, *domo*, *ra*, *syo*, which signify all, much, many; or by reduplication, as *fito-bitō*, men, from *fito*, man, with altered initial. The genitive precedes: *fitono yomi*, Lat. *viri arcus*; *anagono*, *fana*, *mulieris flos*. The numerals are various. We give here the Koye in the first place, and within parentheses the Yomi or common ones first, and after them those of days, namely: 1, *itsi* (*nitots'*, *tsuitats'*); 2, *ni* (*fatots'*, *futska'*); 3, *san* (*mits'*, *mika*); 4, *si* (*yots'*, *yokka*); 5, *go*, (*itsots'*, *itska*); 6, *vok* (*mots'*, *muika*); 7, *sitsi* (*nanats'*, *nanuka*); 8, *fats* (*yats'*, *yôka*); 9, *kô* (*kokonots'*, *kokonoka*); 10, *yo*, (*iovo*, *tvovka*), etc. The other Koye are: 11, *syo-itsi* (*10 + 1*); 12, *syo-ni* (*10 + 2*), etc.; 20, *ni-syo* (*2 × 10*); 30, *san-syo* (*3 × 10*), etc.; 100, *fyak*; 1,000, *sen*; 10,000, *man*; 100,000, *vok* (and *rak-sya*, Sanskrit *lak-sha*, a lac); 1,000,000, *teô*; 10,000,000, *kei* (*kotsi*, Sanskrit *koti*). There are 3 sets of figures of numbers. Many particular words are also used in the sense of numerals, as in Chinese. Of pronouns, those of the 1st and 2d person seem to have been lost in the words of etiquette. I, to equals and inferiors, is *vasi*, to a superior, *vatakusi*; we, to equals or inferiors, *vasi-domo*, to superiors, *vatakusi-domo*. There are more than 12 ceremonious quasi-pronouns for the 2d person. The 3d is *ano fito*, this man, etc. (as in Korean). There are many demonstratives. Relatives are wanting, being supplied by participles or understood from the context of the phrases, thus: *vasino miru sto*, Lat. *mei (mih) visus vir*, for *vir quem vidi*; but *vasivo viru sto*, *me videns*, *vir*, for *vir qui me vidit*. The verb is the most perfect part of Japanese speech. *Aru* (to be, or to act), united with nouns, produces many compound verbs. It is affected by many moods, voices, and other logical categories, as in the Altai-Uralic and in many American languages; as for instance: *tata-ku*, Lat. *fer-ire*, *percui-ere*; *tata-keru*, *ferire posse*; *tata-kerareru*, *percuti jubere*; *tata-eteoru*, *percutientem esse*; *tata-kau*, *se muovere ferire*, *pugnare*; *tata-sashereau*, *facere ut inter se pugnent*, *bellum circere*, etc., to a greater extent than the Semitic *kal*, *piel*, *nifal*, *hitel*, *hith-pael*. The suffixes of the tenses are: present, *ru*, past *ta*, future *o*; of negation, *nu*, *zu*. Persons and the plural are indicated by pronouns. The theme of the verb, which is also a substantive noun, is employed without alteration if others follow, and receives the suffixes only when it is not followed by others, or when it is the last word in the phrase. Various euphonic modifications take place in such a combination with the suffixes. Certain particles denote the moods. The participle is of very extensive application, rivaling that of the Greek. Adverbs are like adjectives, as in certain German phrases. The syntax adheres to a strict order, which is: first the subject (nominative), then

the object, attributes, the verb, and the conjunction last. Many of the simple words abound in significations, which must be discriminated by sinograms. Compounds and derivatives are as frequent and easy as in Greek or German. Examples of the former are: *kara-mi*, Lat. *corporis truncus*; *kono-mi*, *arboris fructus*; *futa-no*, *telæ paginæ*; *tsi-sivo*, *pectoris liquor* (blood); *yamabato*, mountain bird, wild pigeon. Derivatives from *stat*, under, below, inferior, are: *stativa*, humility; *statno*, humble; *statni*, humbly; *stat-nisheru*, to humble; *stat-ninaru*, to be humbled; *stat-vonarsu*, to cause humiliation, etc. Other derivatives are: *yomo*, to read, *yomi*, reading, *yomite*, reader; *itamo*, to afflict, *itami*, affliction; *orano*, to hate, *orani*, hatred; *kako*, to write, *kakite*, writer, etc. The following are paraphrases for avoiding ambiguity: *fai-torigumo*, fly-catch-spider, for *kumo*, which means cloud as well as spider; *ine-kari-gama*, rye-cut-scythe, for *kama*, scythe, frog, dish, etc. Many synonyms need explanation, as given in lexicons, where they are determined by sinograms, as for instance *ka-yari-bi*, fire-drive gnats, because each of the three words has different meanings; *kami-fusuna*, a paper cloak, because *kami* signifies paper, god, head, above; *kino-doku*, mind-poison, grief; *ine-bikari*, rye-splendor, lightning; *issun-bosi*, one-inch-bonze, for dwarf, etc. The following are examples of plurisignificants: *in-yen*, cause, banquet; *idsiu*, to inhabit, to leave the house; *kanten*, heat and cold (so in Latin, *altus*, high and deep, *calidus* and *gelidus*, Eng. *coal* and *cool*, etc.). Many Yomi and Koye coincide, others diverge altogether in signification; thus: *kiba*, Japanese, tool, Chinese, cavalry; *kido*, Japanese, city-gate, Chinese, joy, anger, etc. The adoption of Roman script of the English alphabet as a substitute for her ancient system of ideography, is one of the most remarkable and not least important of all Japan's steps toward harmonizing herself with the highest civilization of Europe and America. For several years a knowledge of Roman script has been increasing in Japan among the most highly educated. Now it is proposed by the most influential educational organization in the empire to make the teaching of our alphabet and of our mode of word formation compulsory and universal in the public schools. It seems probable that the government will adopt the proposal, in which case, of course, all private schools will have to do the same, with the result that all the children of Japan will be learning to write and read their own language in English fashion.

At present the great stumbling block in the way of mastering Japanese is the necessity of learning a multitude of different ideographs. Once Japanese words are expressed in letters like our own, the task of learning will become immeasurably easier. It will then also be much easier for the Japanese to learn our language, for of course our alphabetically formed words seem as strange to them as their ideographs do to us. Moreover, it will cause a change amounting almost to transformation in the Japanese mind, or in the linguistic functions of that mind. The Japanese will for the first time regard words not as indivisible integers of speech, but as composite things formed of letters.

JAPAN

The literature of Japan comprises works of all kinds, histories, geographical and other scientific treatises, books on national history, voyages and travels, moral philosophy, dramas, romances, poems, dictionaries, and cyclopaedias. A collection of the works of their poets, accompanied by short memoirs, has been made, and almost every Japanese is familiar with the best passages of the principal poets, and fond of quoting them in conversation. Many of their novels are said to be interesting, and to exhibit a higher imagination and more truth to nature than is found in the fictions of other Oriental nations. Their dramas, of which the people are passionately fond, are generally founded on national history or tradition, or the exploits, lives, and adventures of Japanese heroes and gods. Some of them are designed to illustrate and enforce moral precepts. Their general tendency is said to be elevating, patriotic, and decorous, though some of them are strongly tainted with the national passion for revenge, and have horrible exhibitions of cruel punishments. The unities are totally disregarded, and the scene shifts from country to country and flies over great spaces of time without much regard to probability. Only two actors are usually upon the stage at the same time, and the female parts are performed by boys, as was formerly the case in Europe. The actor is most esteemed who can most frequently change parts in the same piece, and the leading actors receive very high pay.

Art.—Japan is in every sense an artistic nation. Owing to the timber construction that prevails in the buildings, which are marked by the characteristics of braced uprights, the overhanging curved roof, and an absence of arches, the architecture of Japan presents no very striking features except in the wealth of ornamental detail and brilliant color. The most imposing architectural monuments are various temples of which two of the earliest and finest are the 7th century hondo or chief temple of Horinji, Yamato, and the pagoda of Yakushiji, near Nara. In sculpture and carving, however, their work is fine almost to microscopic detail, while still preserving the big effect. Their statuary, dating from the 8th century, is marked by a vigor and freedom of design which has resulted in a standard of high artistic merit. In their bronze statuettes and in carving in wood and ivory they are unsurpassed. The artists love to represent Japanese life as it exists, and the incidents of every-day life, more especially the comical and grotesque, are worked out in wood with extraordinary skill. But it is by painting, especially, that Japanese art is best exemplified.

In Japan the art of painting is of such ancient date that its origin is shrouded in the mists of antiquity. China, India, Korea, and Persia exercised a notable influence upon early Japanese art, but its history cannot be traced back farther than the 9th century.

In the Japanese dwelling there are no pictures, according to the conventional acceptance of the term, in their place is the kakemono, a gay and pleasing mural hanging, consisting of a strip of silk, satin, or crêpe, painted in a bold design of flowers, birds, or figures. This silk, often of thin or transparent texture, is sized in such a manner that it becomes an excellent vehicle for the retention of transparent washes in India-ink or water-colors.

The kakemono is appropriately framed in bands of rare brocade, gold or silver cloth, or of silk or paper decorated with a painted pattern. The bordering usually harmonizes in design and color with the subject. A glittering golden network is sometimes placed at the top or bottom, a silken fringe or other suitable finish. It rolls up like a map, and is weighted at the bottom with a cylinder of wood, bone, or ivory. From this cylinder sometimes depend handsome tassels of silk or carven ornaments of bronze, bone, or ivory; but these ornaments are admissible only on very expensive examples. When not in use the panel is carefully rolled up, deposited in a box covered with silk or paper, and put away until it is needed.

The kakemono has no determinate dimensions, the size being governed by the whim of the artist, or the space in which it is to be hung.

The kakemono is invariably assigned to the place of honor in a home, and is hung in a receptacle known as the tokonoma. This is a hooded and partitioned recess made of bamboo or some light wood, built at right angles with the wall of the room, and so constructed that it always commands a good light. These panel pictures are changed as often as three times a week, changes being governed by the season, occasion, or rank of company expected. The kakemono is a favorite adornment for the tea-house, the gayest ones being selected for this purpose.

Some of the finest ancient examples are enshrined in sacred temples, many of them being representations of Buddha and the numerous pagan gods worshipped by the Japanese; others are emblematical, consist of holy symbols, and are bordered with the most expensive fabrics.

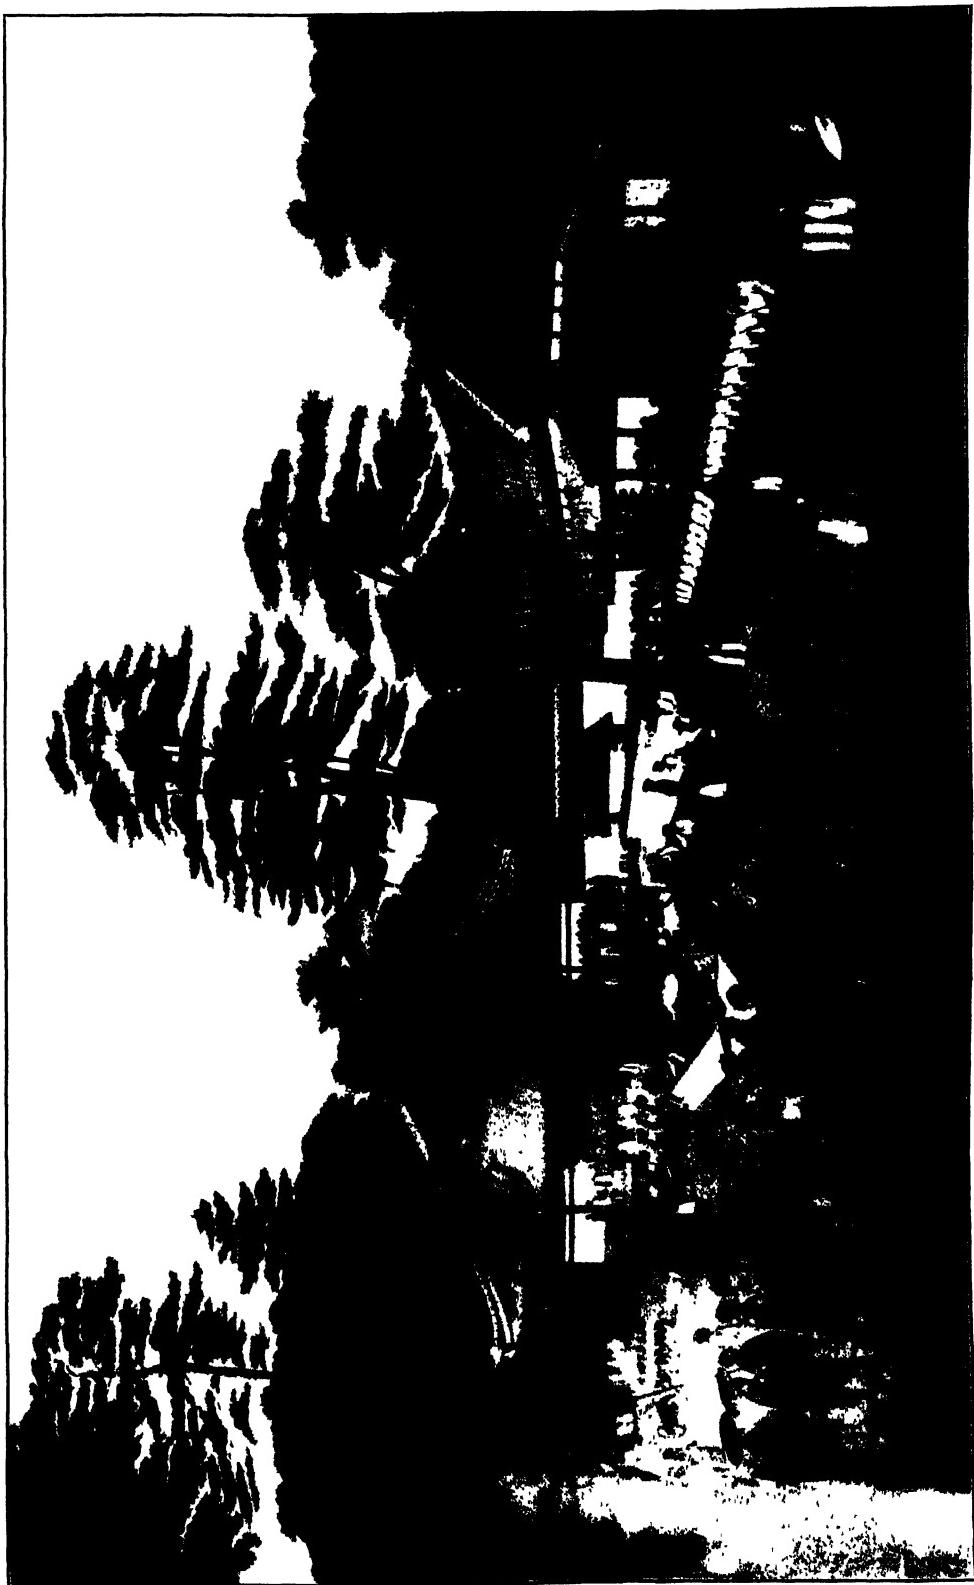

Kosé Kanaoka is said to be the father of Japanese painting; he was the painter and poet-laureate of the imperial court and is regarded as the most eminent artist of antiquity. But few of his works are extant, and they are treasured with such veneration that they are dedicated to the sacred shrines.

Up to the beginning of the 17th century the Japanese painters disdained to reproduce any but heroic and religious subjects. It was not until the 18th century that any paintings portrayed the every-day life of the common people. Four artists soon became celebrated as prominent exponents of this new school of art. Iouasa Matahei was the founder of it, and has presented to posterity the pictorial history of the common people. He shows the peasant laboring in the field, the shopkeeper vending his wares, the artisan plying his various vocations, and the courtesan with her painted cheeks and gorgeous raiment. Hence the kakemonos of Matahei are of inestimable worth to the antiquarian, as they depict with admirable fidelity the manners and costumes of old times.

Motonobou was another able exponent of the realistic school; he began life as an art-embroiderer, and the embellishment of textile fabrics with fine needlework was due to his influence. It was he who created the fashion of the sumptuous trained robe still worn by the women of Japan.

Katsou-Kava was also a realist or impressionist. He devoted his talents to painting scenes from the theatre, and also pictures of women engaged in various occupations, with a smiling landscape or a sumptuous interior for a background. These paintings of picturesque peasant

JAPANESE ART—JARARACA

girls, these counterfeit presentments of gaudily apparelled actors, are mostly to be found decorating the walls of tea-houses. Katsou-Kava was an able exponent of this school of art, which had many followers; he revelled in brilliancy of color, and under his skilful fingers the saffron yellows, the turquoise blues, and the rich violets were blended into a harmonious ensemble with consummate skill; his figures seemed imbued with life and motion.

Yeisai was one of the most delicious colorists of the latter-day impressionistic school, and is responsible for originating the exaggerated type of female who soon became the fashion in the cities of Japan. Although these exaggerations shock our refined tastes, we cannot fail to admire the voluptuous grace of his women, clad in the sumptuous stuffs that the looms of the Orient alone can produce. Another painter fond of portraying females of the refined aristocratic type was Outamaro, whose women are imbued with a languid sensuous charm. His paintings greatly resemble those of the modern French school, and remind one of a mellow rhythmical harmony in music.

Hakousai is undoubtedly the greatest painter, from a European standpoint, that Japan has ever produced, and may justly be compared with the most distinguished painters of Europe. His works are a veritable encyclopædia of dress and customs, but he was pre-eminently the artist of the people, and died unrecognized by the aristocratic classes.

Science.—In science the Japanese cultivated particularly medicine, astronomy, and mathematics. Superstitious prejudices prevented them from studying anatomy by dissection, and they therefore were but little skilled in surgery, but as physicians were able to cope with the most difficult and dangerous diseases. Chemistry also was imperfectly studied, but botany was successfully pursued. Great advance has been made along all scientific lines under the modern regime. As astronomers the Japanese made considerable progress, being well acquainted with the best European treatises either in the vernacular or by translations, and soon equipped their observatories with excellent instruments of native manufacture, and published annually good almanacs, including the calculations of eclipses.

Music.—Japanese music is generally disagreeable to occidental ears, though the people themselves take a passionate delight in it. The use of the samsie or native guitar is an invariable part of female education. Japanese music is almost identical with that of China, having the same scale, and using an invariable common time. It is marked by monotonous melodies, chiefly in a minor key, and by an excessive use of chromatics.

Japanese (jap-a-nēs' or -nēz') Art. See
JAPAN.

Japanese Deer. See SIIKA.

Japanese Fern-balls. See FERNS.

Japanese Quince, a small species of Pyrus (*P. japonica*), closely related to the typical quince, but cultivated wholly as a flowering shrub, as its small apple-like fruit is of little value. The flowers are large, numerous, early, vary from white to deep crimson, and universally admired.

Japan'ning, the art of varnishing in colors. All substances that are dry and rigid, or not too flexible, as woods, metals, and paper prepared, admit of being japanned. Paper is rarely japanned till converted into *papier mâché*, or wrought into such a form that its flexibility is lost. The article to be japanned is first brushed over with two or three coats of seed-lac varnish to form the priming. It is then covered with varnish, previously mixed with a pigment of the tint desired. This is called the ground color; and if the subject is to exhibit a design, the objects are painted upon it in colors mixed with varnish, and used in the same manner as for oil-painting. The whole is then covered with additional coats of transparent varnish, and all that remains to be done is to dry and polish it. Japanned works are chiefly of iron and tin, such as coal-boxes, trays, tin canisters, etc., which are both rendered ornamental and protected from rust. Much care is necessary to secure a high and equal polish. For a description of the Japanese process see LACQUERING; also see VARNISH.

Japheth, jā'fēth, the second of the three sons of Noah, Gen. x. 1. His descendants peopled Europe and northern Asia. The Armenians, Medes, Greeks, Thracians, etc., were of the stock of Japhet. In Arabian legend he is said to have had 11 sons, each of which was the founder of a nation. Some philologists designate the Indo-Germanic languages by the term Japhetic, thus identifying his progeny with the Aryans; and the patriarch is said by others to be represented by the Japetus of Greek mythology, whose wife was Asia, and bore him a son Prometheus, the founder of civilization.

Japp, Alexander Hay, English editor and author: b. Dun, Forfarshire, 25 Dec. 1839. He was educated at Edinburgh University, and was for several years sub-editor of 'Good Words' and the 'Contemporary Review' and editor of the 'Sunday Magazine.' Several of his works have appeared over various pseudonyms—"H. A. Page," "Benjamin Orme," and others. He wrote: a 'Life of Thomas De Quincey' (1874); 'Thoreau: his Life and Aims' (1878); 'German Life and Literature' (1881); 'De Quincey Memorials' (1885); 'Cuckoos and other Parasitical Birds' (1899); 'Darwin and Darwinism' (1900); 'Darwin as Ethical Thinker' (1901), and other volumes.

Japura, zhā-poo-rā'. See YAPURA.

Jararaca, zhā-rā-rā-kā', a venomous crotaline serpent (*Lachesis jararaca*) of northeastern South America. Compare BUSHMASTER.

JARO — JASMINE

Jaro, hā'rō, a pueblo of the province of Iloilo, Panay, situated on the Jaro River four miles northwest of Iloilo, the provincial capital. It is one of the earliest Spanish settlements in the Philippines, having been founded in 1584; in 1865 it was made an Episcopal see. The river is navigable for native boats and there is considerable trade. Pop. 10,400.

Jarool', an English spelling of the native name of an East Indian tree (*Lagerstræmia Ros-reginæ*). It has large purple flowers, and yields valuable timber.

Jarves, jär'ves, James Jackson, American art writer: b. Boston, Mass., 20 Aug. 1818; d. Tarasp, Switzerland, 28 June 1888. In 1838, in consequence of ill health, he sailed for the Sandwich Islands, and resided for several years in Honolulu, where he published the first newspaper ever printed there, the *Polynesian*. Before returning to the United States he traveled extensively in California, Mexico, and Central America, and subsequently published a 'History of the Hawaiian or Sandwich Islands' (1843); 'Scenes and Scenery of the Sandwich Islands' (1844); and 'Scenes and Scenery in California' (1844). He afterward resided in Europe, chiefly in Florence, devoted to the study of art and engaged in making a collection of old masters which eventually became the property of Yale University. For his services to Italian art the king of Italy made him a chevalier of the Crown of Italy. His later works include: 'Parisian Sights and French Principles' (1855-6); 'Art Hints' (1855); 'Italian Sights and Papal Principles' (1856); 'Kiana, a Tradition of Hawaii' (1857); 'Confessions of an Inquirer' (1857); 'The Art Idea'; 'The Old Masters of Italy' (1861); 'Glimpses at the Art of Japan' (1876); 'Italian Rambles' (1884).

Jar'vis, Abraham, American Protestant Episcopal bishop: b. Norwalk, Conn., 5 May 1739; d. New Haven, Conn., 3 May 1813. He was graduated at Yale in 1761, and in the autumn of 1763 sailed for England, where he was ordained deacon in February, 1764, and priest a few weeks later. He left England in April, and was settled as rector of Christ's church, Middletown, Conn., the same year. In 1797 he became the second bishop of Connecticut.

Jarvis, John Wesley, American painter: b. South Shields, England, 1780; d. 1840. John Wesley was his uncle and sent him in his fifth year to Philadelphia, where his father, a seafaring man, had settled. Jarvis had but little regular art training, but was encouraged by Malbone. He had a studio in New York and painted portraits of statesmen, preachers and soldiers, some of which are in the City Hall, New York, and in the collection of the New York Historical Society.

Jasher, já'shér, Book of, a lost book of the Hebrew Scriptures, twice mentioned in the Bible (Josh. x. 13, and 2 Sam. i. 18), and about which various conjectures have been made. It was most probably a national song-book of post-Solomonic age, whose contents were partly secular, partly religious. From the mention of the book in Joshua and 2 Samuel it has been inferred that the book of Joshua could not have been written before the time of David's lamentation. But this assumes that the book of

Jasher was all written at once, an assumption which in our ignorance regarding it we are not at liberty to make; for the book of Jasher may have been written at different times. The theory of Dr. Donaldson as to its scope and contents, in conformity with which he proceeded to reconstruct it from the fragments which he thought he could trace throughout the several books of the Old Testament, has met with little favor either from English or Continental scholars. See Donaldson, 'Fragmenta Archetypa Carminum Hebraicorum in Masorethico Veteris Testamenti Textu passim tessellata.'

Jasmin, Jacques, zhák zhás-mán (Provençal, JAQUOU JANSMIN), Provençal poet: b. Agen 6 March 1798; d. there 4 Oct. 1864. In his 'Mous Soubenis' (My Recollections) he gives a humorous description of the humility of his origin and of the poverty of his kindred. All his poems and songs are written in the patois of the peasantry on the banks of the Garonne, supposed in its purest state to be identical with the old Provençal, the language of the troubadours. His poetry deserved and acquired more than a local celebrity, and was warmly welcomed not only in Southern France, but throughout the whole of Europe. He was elected a member of the academies of Agen and Bordeaux; the city of Toulouse awarded him a gold laurel; and in 1846 he was created a Knight of the Legion of Honor. The poetry of Jasmin is distinguished by beauty and power, and though his genius inclined him to gaiety rather than to pathos, yet perhaps his most striking and successful passages are those in which he addresses himself to the feelings. His principal works are: 'The Charivari', (1825), a mock-heroic poem; 'Lou Tres de May' (1830), an ode; 'The Blind Girl of Castel Cuillé' (1836), his masterpiece in poetry, which has been translated by Longfellow; 'The Curl-papers of Jasmin' (1835); 'Francouneto' (1842); 'The Two Twin Brothers' (1846); 'Maltro L'Innocento' (1847); and 'La Semmano d'un Fil' (1849). Consult Rabain, 'Jasmin, sa vie et ses œuvres' (1867); Montrond, 'Jasmin, poète d'Agen' (1875); Andrien, 'Vie de Jasmin' (1882); Smiles, 'Barber, Poet, Philanthropist' (1892).

Jas'mine, or Jessamine, a genus (*Jasminum*) of beautiful plants of the olive family, including many cultivated species and varieties. Most of these are shrubs with long twining branches bearing usually compound leaves and panicles of fragrant white or yellow flowers. They are natives principally of the East Indies. The common jasmine (*J. officinale*) has become naturalized in the south of Europe, where it grows eight or ten feet tall, and is practically an evergreen. The oil of jasmine is obtained from *J. officinale* and *J. grandiflorum*, but it is usually imitated or adulterated. *J. sambac* also furnishes an oil in the East; and a very common greenhouse species is *J. humile*.

Several shrubs are called jasmines which are only loosely related to the true jasmine. Thus the red jasmine of the West Indies (*Plumeria rubra*), the source of the perfume frangipanni, is of the oleander family; the Chile jasmine, *Mandevilla suavolens*, is another fragrant species of the same family, widely cultivated, and others might be mentioned. Two of these outside "jasmines" are familiar in the United States, one of which is a native. The Cape jasmine

JASON—JASTROW

(*Gardenia florida*) is a Chinese (not South African) shrub of the madder family, which found its way to England and America about the middle of the 18th century; it is cultivated everywhere in greenhouses, in a double-flowered variety; and it grows out of doors along the southern seaboard, it being the special pride of Charleston, S. C., after one of whose citizens the genus *Gardenia* was named by Linnæus.

The native species is the Carolina or yellow jasmine (*Gelsemium sempervirens*), an exceedingly odorous climbing plant of the family *Loriaceae*, common throughout the South Atlantic States. It is a vine, whose blossoms grow in axillary racemes of from one to six vivid yellow tubular flowers; and "evening trumpet-flower" is a common name. "Early laden, indeed, is the warm air of spring with its delicious perfume. . . . Through woods and thickets it wends its way vigorously and gleams as brightly as does later the Cherokee rose. It is one of the joys of the season." The roots are regarded by the country people as possessed of medical virtues.

Ja'son, in Greek legend, the son of Aeson, king of Iolcos in Thessaly, a hero of ancient Greece, celebrated for his share in the Argonautic expedition, before which he had distinguished himself in the Calydonian hunt. He belonged to the family of the *Aolidæ* at Iolcos, and his instructor was the centaur Chiron, who educated most of the heroes of that time. (For his adventures in the Argonautic expedition see ARGONAUTS.) On his return to Iolcos with Medea as his wife he avenged the murder of his parents and his brother by putting Pelias to death. But he was unable to retain possession of the throne, and was obliged to resign it to Acastus, son of Pelias, and flee with his wife to Corinth. Here they passed ten years, till Jason, wearied of Medea, fell in love with Glauce (Creusa, according to some accounts), daughter of Creon, king of Corinth, married her, and put away Medea and her children. Medea, having revenged herself on her hated rival, fled from the wrath of Jason in her car drawn by winged dragons, the gift of Helios, to Ægeus, king of Athens, after she had put to death Mermerus and Pheres, her sons by Jason. According to some, Jason killed himself from grief; but others relate that, after passing a miserable wandering life, he came to his death by accident. Others say that he was reconciled to Medea, and returned with her to Colchis, where he ruled many years.

Jas'per, William, American soldier: b. South Carolina about 1750; d. Savannah, Ga., 9 Oct. 1779. At the commencement of the revolutionary war he enlisted in the 2d South Carolina regiment, in which he became a sergeant. Subsequently, in the attack upon Fort Moultrie by a British fleet, he distinguished himself by leaping through an embrasure to the ground, under a shower of cannon balls, and recovering the flag of South Carolina, which had been shot off. Governor Rutledge presented him with his own sword, and offered him a lieutenant's commission; this, however, Jasper declined, saying: "I am not fit to keep officers' company; I am but a sergeant." His commander gave him a roving commission to scour the country with a few men, and surprise and capture the enemy's outposts. His achievements in this capacity

seem to belong to romance rather than history and in boldness equal any recorded in the revolutionary annals of the southern States. Prominent among them was the rescue by himself and a single comrade of some American captives from a party of British soldiers, whom he overpowered and made prisoners. At the assault upon Savannah he received his death wound while fastening to the parapet the standard which had been presented to his regiment. His hold, however, never relaxed, and he bore the colors to a place of safety before he died. A county of Georgia and a square in Savannah have been named after him.

Jasper, Ind., town, county-seat of Dubois County; on the Patoka River, and on a branch of the Louisville, E. & St. L. railroad; about 47 miles northeast of Evansville. Jasper is situated in an agricultural region. The chief manufacturing establishments are saw-mills, lumbering and planing-mills, flour-mills, a furniture factory, and a brick-yard. Pop. (1900) 1,863.

Jasper, an impure quartz, less hard than flint or even than common quartz, but which gives fire with steel. It is entirely opaque, or sometimes feebly translucent at the edges, and presents almost every variety of color. It is found in metamorphic rocks, and often occurs in very large masses. It admits of an elegant polish, and is used for vases, seals, snuff-boxes, etc. There are several varieties, as red, brown, blackish, bluish, Egyptian. Ribbon or agate jasper is jasper in layers.

Jassy, yās'sē, Rumania, the former capital of Moldavia; on the Bahluiu River. The churches and educational institutions are quite noted; the industrial enterprises are few; but the commerce is extensive and important. The chief exports are petroleum, grain, meat, and salt; the chief imports are coal and clothing. It was in Jassy, in 1821, that Alexander Ypsilanti really began the work for Greek independence. About one-half the population are Jews. Pop. (1902) 80,500.

Jastrow, jās'trō, Joseph, American psychologist: b. Warsaw, Poland, 30 Jan. 1863. He was a son of Rabbi Jastrow (q.v.) and came to America in childhood. He was graduated from the University of Pennsylvania in 1882 and has been since 1888 professor of psychology at the University of Wisconsin. He became president of the American Psychological Association in 1900. He has published "Time-Relations of Mental Phenomena" (1890); "Epitomes of Three Sciences" (1890); "Fact and Fable in Psychology" (1900); "Modern Psychology."

Jastrow, Marcus M., American rabbi and lexicographer: b. Rogasen, Posen, 1829; d. Germantown, Philadelphia, 13 Oct. 1903. After the usual rabbinic and academic studies he graduated from the University of Halle in 1854, became a barber in Berlin, and then rabbi at Warsaw. After five years he was obliged to leave by reason of his political opinions, after being subjected to arrest. He was called to the Congregation Rodef Sholen, Philadelphia, in 1866, with which he was connected until his death, within recent years as rabbi *cmeritus*. Besides some monographs and contributions to the press, he is best known for his "Dictionary of the Targumim, the Talmud Babli and Yerushalmi, and the Midrashic Literature," which is nearing

JASTROW — JAVA

completion (1903) and is a monument of untiring erudition and broad scholarship.

Jastrow, Morris, Jr., American Orientalist: b. Warsaw, Poland, 13 Aug. 1861. He was a son of the preceding, and coming to Philadelphia with his parents in early childhood, he was trained in the schools of that city, graduated from its university in 1881, and from the University of Leipsic 1884. He has been for many years professor of Semitic languages and librarian of the University of Pennsylvania. He was originally trained for the Jewish ministry, studying for some time at the Jewish Seminary of Breslau, Germany, and was appointed assistant to his father's synagogue, Philadelphia, which position he voluntarily resigned. His published works are: 'Religion of the Assyrians and Babylonians' (1898); 'Two Grammatical Treatises of Abu Zakariyya Hayyug' (1897); 'A Fragment of the Babylonian Dibbarra Epic' (1891); 'The Study of Religion' (1901). He has edited 'Selected Essays of James Darmesteter' (1895). He is a frequent contributor to learned periodicals and to various encyclopædias.

Jatrophæ, jät'rō-fa, a genus of euphorbiaceous plants of the tribe *Crotoneæ*, tropical and chiefly American. They are of interest principally for their medicinal properties, which reside mostly in the seeds. These, in the case of *Jatrophæ curcas*, are called Barbados or physic nuts,—the last in allusion to their purgative power. The so-called jatrophæ-oil is extracted from the seeds of the coral-plant (*J. multifida*) and of the East Indian *J. glauca*, and is used externally as a stimulant. A common species in the southern United States is the spurge-nettle or tread-softly (*J. stimulosa*). Compare MANTHOT.

Jats, jâts, the most numerous of the agricultural population of the Panjab, India, numbering about four and a half millions. They are by many identified with the *Getæ*; and some of the best authorities accept the theory that they are descended from Scythian invaders of India in prehistoric times. Some scholars believe them cognate with the Gypsies (q.v.).

Jaundice, jän'- or jän'dis, a morbid condition arising from the circulation of bile in the blood, with consequent staining of the tissues and a peculiar train of symptoms resulting from the poisoning. The tint of the skin and certain mucous membranes varies from a light yellow to a brownish or saffron hue. Staining of the conjunctiva is first observed, and is most intense. Jaundice, with reference to its origin, may be either obstructive or toxic. The term obstructive means causing a hindrance to the outflow of the bile from the gall-ducts into the intestine, with its consequent absorption into the hepatic vein and general circulation. Not only is the skin stained, but all the secretions as well, the urine becoming dark brown. As no bile is thrown into the intestine, the stools become clay-colored and usually hard. There is frequently distressing cutaneous itching, and other skin-maladies are not uncommon. The blood partially loses its power of coagulation, and the vessels are apt to allow the escape of blood into the tissues, giving rise to purpuric spots. The pulse is usually slow, and the patient somewhat melancholic. In bad cases death may follow a period of convulsions, delirium or coma. The

cause of this obstruction may be anything occluding the lumen of the ducts from within, as catarrh of the membrane of the intestine, where the bile-ducts open, or catarrh anywhere along the course of the ducts; stones or thickened bile may block up some part of the tubes, or they may be occluded from pressure on the outside by tumors, constricting bands, or shrinking of the liver-substance. (See LIVER, DISEASES OF THE.) The toxic form of jaundice is due to the circulation of poisons in the blood which break down the red cells or, more rarely, destroy the liver cells. The jaundice in this form is not so intense, and the other symptoms caused by the poison are of more importance. Many of the infectious diseases, such as influenza, typhoid fever, yellow fever, pneumonia, pyæmia, and acute atrophy of the liver, cause this form. Mineral poisons, particularly phosphorus, act in the same way. Jaundice in the new-born is so common as to be considered a natural condition, and usually lasts but a few days. It is evident from the many conditions that may give rise to jaundice that it must be considered as a symptom, and treatment should be directed to aiding the bodily functions until the exact cause can be determined.

Jauré, Jean Leon, zhōn lá-ōn zhō-rā, French Socialist: b. Castres 1859. He taught at Albi and Toulouse, and in 1885 entered politics and was elected to the Chamber of Deputies from Tarn; at this time he was a moderate Republican. In 1889 he failed of re-election, and returned to Toulouse, where he was active in the establishing of a college of medicine. Becoming a Socialist, he defended the strikers at Carmaux, and in 1893 was again elected to the Chamber, where he became one of the leaders of the Socialists. He failed of re-election in 1898, but was again elected in 1902. When the Socialist Millerand accepted a position in the cabinet, Jauré defended his action, thus opposing Guesde and the *Parti Ouvrier*, but sought at the same time to reconcile the factions. He also took an important part in obtaining a revision of the Dreyfus case. He still holds a position of leadership and influence in the Socialist party of France, and is acknowledged to be one of the best orators in the chamber of deputies.

Java, jā'vā (native, *Siti-Java* or *Yava*, land of millet), an island of Dutch East India; situated between lat $5^{\circ} 52'$ (Saint Nicholas Point), and $8^{\circ} 50'$ (South Cape) S.; and lon. $105^{\circ} 13'$ and $114^{\circ} 39'$ E. The island is bounded on the north by the Java Sea, on the east by Bali Strait, which separates Java from Bali Island, on the south by the Indian Ocean, and on the west by Sunda Strait which separates the island from Sumatra. It extends east and west, declining 15° toward the south. It is about 660 miles long, from 40 to 125 miles wide, and the area, including Madura Island, off the east coast, is about 50,554 square miles. The Indian Ocean, which beats with great force along the south coast, has prevented the formation, on that side, of such alluvial plains as extend along the north coast. From the same cause the south coast is generally unsafe for shipping, while the north affords excellent anchorage at almost all times and places. The south presents a continuous front of crags and rocks, forming the outer edge of an extremely mountainous country; the north is flat and low, and covered in

JAVA

many places with mangrove swamps. The chief harbors on the north are those of Surabaya and Batavia; on the south that of Chilatjap, formed by the small island Kambangan.

Topography and Hydrography.—The whole configuration of the island has been transformed by volcanic action. There are at least 50 volcanoes in Java, of which half are active. In the western end of the island they are grouped in a mass and attain a height of 10,000 feet, but in the eastern portion, though more scattered, they are generally higher, one, Semeru, 12,044 feet, being the highest in the island. Among the chief are Salak (7,266), near Batavia, now extinct; Gedé (9,720); Tjirmaj (10,075); Marbabu (10,670); Raun (10,820); Slamar (11,250). Papandayang, in the southwest, destroyed about 3,000 persons in 1772. In 1822 great damage was done by the eruption of Galungung, one of the volcanoes in the western part of the island. In 1686, about 10,000 lives were lost by the eruption of Ringghit, once over 12,000 feet high, but now a low mountain. The eruption of Kloet (q.v.), in 1901, was most disastrous. The eruption of Krakatoa (q.v.) in 1883, was one of the horrors of modern times.

The island is subject to earthquakes, usually not severe. Three earthquakes are known to have preceded and 19 accompanied volcanic eruptions. In 1867 occurred a most destructive earthquake. A low range of non-volcanic hills, about 3,000 feet high, extends along the south coast. The crater of an extinct volcano called Guwa Upas, or the Vale of Poison, about one half mile round, is held in horror by the natives. It is said that every living creature that enters it drops dead, and the soil is covered with the carcasses of deer, birds, and even the bones of men, killed by the carbonic acid gas which lies in the bottom of the valley; but its terrors have been much exaggerated. "In another crater in this land of wonders," says Sir Charles Lyell, "the sulphureous exhalations have killed tigers, birds, and innumerable insects; and the soft parts of these animals, such as the fibres, muscles, hair, etc., are very well preserved, while the bones are corroded and entirely destroyed." Numerous rivers flow from the north and south sides of the mountains, carrying fertility with them, and affording supplies to innumerable artificial water-courses used in irrigation. These streams are generally rapid, shallow, and so encumbered with sandbanks as not to be navigable; so that only two rivers, the Solo and the river of Surabaya, are navigable for large boats; the others are only suitable for proas or canoes of the lightest draught, or for floating down timber from the mountains. The Tji Tarun and the Tji Manuk are navigable a part of the year.

Climate.—Java is considered fairly healthy, but proper care must be taken to avoid the excessive heat of midday and the night air from the marshes. The temperature of the plains and valleys is during the day from 85° to 94° F., and during the night from 73° to 80°. At an elevation of 6,000 feet the thermometer descends to 60°, while the tops of the highest peaks are often covered with ice but no snow falls. The breezes from the water modify the temperature. There are two seasons; the dry from April to October, and the rainy season from October to

April. During the rainy season there is an almost continuous rainfall except for a short time in the morning. The annual rainfall is about 80 inches. The island is not subject to storms which injure life or property, but near the high mountains there are frequently thunder storms.

Geology.—Java is formed mainly of tertiary, though partly of post-tertiary strata; but by volcanic action the arrangement has been much disturbed. Rocks containing fossil invertebrates are common, but the fossils of vertebrates have not been discovered. There are no metallic veins of sufficient length or depth to be profitable for mining; the Bantam coal-mines, in the northwestern part of the island, yield only lignite; sulphur, naphtha, and asphalt are found in several places, and small quantities of salt saltpeter, and magnese. Limestone and marble are in the southern part. Its minerals are not considered of sufficient value to be classed among its natural wealth-producing resources.

Vegetation.—With a temperature ranging from 94° to the freezing-point, a volcanic soil plenteously watered naturally and artificially, it is not surprising that Java should be of astonishing fertility; the range of its vegetation naturally follows that of its temperature, from the palms of the tropics to the mosses of the temperate zone. The coast is fringed with cocoanut trees; behind them the ground rises gently to the foot of the mountain chain, and is completely cultivated. Vast fields of rice, artificially watered, distributed amphitheatrically on the flanks of the hills, yield often three harvests annually. In the same altitude are found the cotton plant, the mangoes, sugar-cane, indigo, palm-trees, and other tropical vegetation. Higher up than the rice-fields the bases of the mountains are covered with vast forests of the fig-tree tribe of different species, remarkable for their great height and vigorous growth. Tea, coffee, fruits, cinchona, sandalwood, mahogany, camphor, bamboo, rattan, and many other forms of vegetation are found in this altitude of from 2,000 to 4,000 feet. These are followed still higher up by the plane-like liquidambars, with their erect stems covered with parasites, also rattans and *Rubiaceæ*, the latter of numerous species, some of them exhaling a very foetid odor. Along the upper limits of the liquidambars about 4,000 feet above the sea, lofty trees are still plentiful; here may be seen *Podocarpus cupressus*, with its lofty straight stem, a tree allied to the yew, and furnishing the best timber in Java; the Dammar pine, rhododendrons, laurels of numerous species, chestnuts, oaks, and several others, magnolias, myrtles, tobacco, maize, potatoes, and other vegetation common to the temperate zones. About 7,000 feet high the vegetation changes its aspect, and mosses appear, which, with heaths, are the principal plants found on the loftier elevations. Before leaving the natural vegetation the famed poison-tree, the chettik or upas (*Antiaris toxicaria*), may be named as a noted Javanese plant. The vast forests likewise claim notice; they are 791 in number, and cover a very extensive surface in 13 of the provinces, and consist mainly of teak. To prevent the waste which was going on, the government has placed them under superintendence,

JAVA

and draws from them a large amount of revenue.

Animals.—Including domestic and marine animals 100 kinds of mammalia inhabit Java. In the west part the one-horned rhinoceros is not uncommon; and in the higher districts the royal tiger, panther, and tiger-cat keep the inhabitants in constant alarm by their depredations. The babioussa and two kinds of wild hog form the large game of the island. There are only two species of the ape kind, but they people the forests in countless numbers. Two kinds of lemurs inspire the inhabitants with superstitious fear by their mysterious nocturnal habits; and this island may be esteemed the native seat of the largest bats, some of which measure five feet across the wings. They may be seen suspended from the branches in hundreds during the day, and at night they devastate the orchards and gardens. Two civets are common, and supply a perfume of which the Javanese are passionately fond; the wild ox abounds in the woods; and the buffalo is the only animal used in agricultural labor. The horses are small, but vigorous, and, as in India, are not used for agricultural purposes. Two species of wild dogs and six species of deer are found here. Among the domestic animals are the buffalo, ox, horse, goat and sheep. The ornithology of Java is rich and varied, both in genera and in species. About 300 species of land birds have been found on the island, among them the peacock, partridge, quail, 10 different species of pigeon, 11 species of heron, two of cuckoo, the woodpeckers, the black and crimson oriole, the hornbill, eagle, owl, the brilliant looking, and appropriately named minaret flycatcher, the "swift" (q.v.), and the minor bird so apt in learning to mimic human speech is common. Almost all the known generic groups of rapacious birds are found here in great numbers, and gallinaceous fowls are plentiful. A variety of reptiles are found on the island, among them the python. Insects cover the grounds and plants in countless numbers; but few are distinguished for brilliancy or variety of color, or are remarkable in form. Fish are plentiful in the rivers and along the coast; but those of the rivers are of inferior quality for food. Excellent oysters are abundant on the north coast, and prawns, from which a condiment called trasi is prepared and considered delicious by the natives. Crocodiles from 20 to 30 feet in length inhabit the water courses.

In 1895 there were in Java in all about 2,643,000 buffalos; 2,572,000 oxen and cows; and 485,500 horses.

Occupations and Productions.—The Javanese are almost entirely occupied in agriculture. There is a small class of fishermen on the north coast, and a few artisans in the towns, but the great bulk of the people live directly or indirectly by the cultivation of the land, in which they have made greater progress than any other Asiatic nation except the Chinese and Japanese. The chief crop is rice, of which with the aid of irrigation, industriously and almost universally applied, two crops are raised in a year. Lands that cannot be irrigated are used for growing pulses, oil-giving plants, cotton, sugar-cane, and tobacco; and on the mountain slopes, at an elevation of 2,000 or 3,000 feet, coffee is cultivated.

"In the most fertile parts of Java," says Crawfurd, "and these from the neighborhood of the high mountains are usually also the most picturesque, the scenery is at once agreeable and magnificent, and certainly for grandeur and beauty excels all that I have seen even in Italy, that country which in summer bears the nearest resemblance to Java. In such situations we have mountains 10,000 feet high, cultivated to half their height, the valleys below having all the appearance of a well watered garden, in which the fruit trees are so abundant as to conceal the closely packed villages." The mechanic arts among the Javanese are not so far advanced as their agriculture. About 30 crafts are practised among them, of which the principal are those of the blacksmith or cutler, the carpenter, the sheath maker, the coppersmith, the goldsmith, and the potter. Bricks and tiles are largely made. The carpenters are skilful in house and boat-building. They make vessels of all sizes from 50 tons down to fishing canoes, and under European superintendence build large ships. The ordinary dwellings of the people are built of a rough frame of timber, thatched with grass or palm leaves, and with walls and partitions of split bamboo. The Javanese excel all other nations of the Malay archipelago in the working of metals. They are especially skilful in the manufacture of the national weapon, the kris or dagger, which is worn by every man and boy above 14 years as part of his ordinary costume, and by many ladies of high rank. They make also excellent gongs of brass, and these with other musical instruments of the same metal have long been exported to the neighboring countries. The only native textile material woven by the Javanese is cotton, of which they make only a stout durable calico, and this is purely a domestic manufacture, carried on exclusively by the women. From raw silk imported from China, the silkworm not being reared in Java, a coarse cloth is woven by the women. Paper of the nature of the ancient papyrus is a manufacture peculiar to the Javanese.

The greater part of the agricultural lands of Java is claimed by the Government of the Netherlands and the private estates are principally in the residencies in the western part of the island. The government or the private landowners can enforce one day's gratuitous work out of seven, and in some cases more, from all the laborers on their estates. In 1882 the greater part of the enforced gratuitous labor for the government was abolished in return for the payment of one guilder (40 cents) per head yearly. In 1900 the natives had under cultivation 7,073,036 acres. Prior to 1891, the government raised sugar; but since 1891 the sugar is all raised on private properties and on lands hired by the natives, or on lands held on emphyteutic tenure from the government. In 1900 the number of sugar estates was 191 and in 1901 the yield of sugar was 766,238 tons. The yield of cinchona for 1900 was 1,415 tons; of tobacco, 5,435 tons; of tea, 1,659 tons; of indigo, 180 tons.

Trade and Commerce.—The trade of Java is now large, and what was once a burdensome colony has become one of the principal sources of wealth to Holland. The great bulk of the

JAVA

foreign trade is carried on through the ports of Batavia, Samarang, and Surabaya. The principal exports are sugar, coffee, cinchona, indigo, nutmegs, mace, cloves, cinnamon, pepper, tea, rice, cocoa, tapioca, cochineal, cubeb, arrack, tobacco, hides, india rubber, and tin. The exports, in 1900, of sugar, and coffee, nearly all of which was sent to Holland, amounted to nearly \$55,000,000. A large amount of rice is sent to Borneo and China. The principal imports are cotton yarns and cloth, machinery, iron, coal, and woolen goods.

Education.—The Europeans and the natives have separate schools with a slight difference in their methods of government. Ample provisions are made by the government for the education of the natives. There are public and private schools, about 20 schools for girls only, and one normal school for the training of teachers for the natives, and two for the training of teachers for the schools for Europeans and those assimilated with them. There is an agricultural college, a museum, and a fine botanical garden at Buitenzorg, and a gymnasium at Batavia. In science the people have made little progress, possessing only a rude notion of astronomy and a slight knowledge of arithmetic. Their architecture at present day hardly deserves the name, though the country abounds with remarkable remains of temples built many centuries ago by the ancestors of the present inhabitants. Of the other fine arts, music is the one in which they have made the greatest progress. They are passionately fond of it, and have generally good taste. Their melodies are wild, plaintive, and interesting, and more pleasing to the European ear than any other Asiatic music. They have wind and string instruments, but their best and most common instruments are drums and gongs.

Religion.—All religious denominations are allowed perfect freedom in Java. The Javanese are Mohammedans, which faith was established by Arab conquerors in the 15th century and has almost displaced Brahminism and Buddhism, the ancient religions of the country. In 1896, in Java and Madura, there were 19,193 native Christians. In 1900 there were about 100 missionaries working among the natives.

Banking.—The "Java Bank," established in 1828, has a capital of \$2,400,000 and a reserve of about \$480,000. The government of the Netherlands has control over the administration. Two fifths of the amount of credits, notes, and assignats must be covered by bullion or specie. In March 1901, the notes in circulation amounted to \$22,534,000, and the bank operations to \$18,637,200. There are postal savings-banks and other savings-banks have been established. The legal coins are the same as those of Netherlands.

Weights and Measures.—The legal weights and measures are the same as those of Netherlands (q.v.).

Ethnology.—The native population of Java comprises two distinct nations, the Sundese and the Javanese. The Sundese occupy the western end of the island, and are greatly inferior in number to the Javanese, and less advanced in civilization. They speak a distinct language. Both nations are of the Malayan race. They are generally about two inches shorter than the men of the Mongolian and Caucasian races, with round faces, wide mouths, high cheek bones,

short and small noses, and small, black, deep-seated eyes. The complexion is brown with a shade of yellow, and is never black. The hair of the head is thick, black, lank, and harsh, and is either scanty or altogether wanting on other parts of the body. A few short, straggling hairs compose the beard. The people are not active, and make but poor runners or wrestlers. They are described as a peaceable, docile, sober, simple, and industrious people. Mr. Crawfurd, author of 'A Descriptive Dictionary of the Indian Islands,' who lived several years in Java, says: "From my own experience of them, I have no difficulty in pronouncing them the most straightforward and truthful Asiatic people that I have met. The practice of running amuck, so frequent with the other cultivated nations of the archipelago, is of very rare occurrence with them." They are patient, enduring, and easily led when convinced that the orders given are not contrary to the ancient laws and customs of the country, which are held in religious reverence. They are very susceptible of affronts, which they are not slow to avenge with the kris, which is invariably worn, and they are frequently likewise armed with the sabre or pike. The mass of the Javanese take only one wife, but people of quality and wealth take advantage of the latitude allowed by the Koran, and practise polygamy. All, without distinction, are passionately fond of gaming, more especially of cock-fighting.

Population.—Java is one of the most densely peopled countries of the world. The population in 1900 was 28,745,698. The population of the principal towns in Java, January 1900, was:

	Euro-peans	Natives	Chinese	Arabs	Orien-tals	Total
Surabaya...	8,906	121,886	13,035	2,791	326	146,044
Batavia....	8,893	77,700	26,817	2,245	232	115,887
Samarang...	4,800	70,426	12,372	724	964	89,286

The whole population of Java is legally divided into Europeans and persons assimilated with them, and natives and persons assimilated with them. The Europeans and those assimilated with them are generally living under the laws which prevail in Netherlands, while the natives and those assimilated with them observe the customs and laws of India. The division of the population into the two classes mentioned is in accordance with the code which specifies the limits and conditions for legislation in Dutch East India. The governor-general, together with the council, has power to make individual exceptions to the general rule.

Government and Revenue.—The most important feature of Javanese society is the village, which forms a complete body politic, with considerable powers of self-government. Its officers are elected by the people, and are charged with the collection of the taxes and the maintenance of public order. The general government of the island is entrusted to a governor-general, appointed by the king of Holland. He is commander-in-chief of the army and navy, and possesses nearly absolute power. Justice is administered to the European inhabitants by a supreme court at Batavia, and by three provincial courts at Batavia, Samarang, and Surabaya. There are besides these other courts for the Asiatic population. In 1832 Gen. Johannes Graaf Van den Bosch introduced into Java a system of government known as the

JAVA

"culture system." In principal, it was based upon the officially superintended labor of the natives, directed so as to produce not only a sufficiency of food for themselves, but a large revenue for Netherlands. This obligatory labor was applied to the culture of coffee, sugar, indigo, pepper, tea, tobacco, and some other products; but at present the labor of the natives is required only for the culture of coffee which is marketed by the Government. By the terms of a bill which passed the legislature of the Netherlands in 1870, the obligatory cultivation of the sugar-cane is now totally abolished.

Java, including the island of Madura, comprises 17 residencies, each governed by a resident, assisted by assistant residents, and other officials. Before receiving government appointments, these officials must first have had examinations. The resident and his assistants, together with a number of native officials, exercise almost absolute control over the province in charge. The native officials are remunerated for their services by salaries or by a per cent on the amount of taxes collected. No law can be enacted or enforced by any governor-general which will conflict with the "Regulations for the Government of Netherlands India," laws passed in 1854 by the king and states-general of Netherlands.

The revenues are derived from the government monopolies of railroads, salt, opium, and from the sale of government products obtained under the "culture system." Other revenues are obtained from taxes on houses and estates, sale of government lands, custom duties, licenses, personal tax, and from a number of indirect taxes. The greatest expenditures are for the general administration, about one third, and for the army and navy another third.

Defense.—The army and navy of Java form a part of the defense of the whole Netherlands India. The army is colonial, and the regular army of Netherlands is not allowed on duty in any part of Dutch East India. The commissioned officers are Europeans, except a few prominent natives to whom honorary offices have been given. One half the non-commissioned officers must also be Europeans. There is a school attached to every battalion, and a military academy on the island of Java, at Meester Cornelis, a place near Batavia.

History.—Ancient Javanese history is written in the still existing magnificent remains of temples and other public buildings, which are plentifully scattered over the island. These attest that the worship of Brahma and Buddha once prevailed in the island under the Hindu empire of Modjopahit, the dismemberment of which was consummated by the Arabs 1478 A.D., by the destruction of a vast capital of that name. Islamism had previously supplanted the rival worship, and had driven their last adherents into the neighboring island of Bali. The island then fell under the dominion of numerous petty chiefs, and was found in that state by the Portuguese, the first European settlers on the island, who arrived in 1511. They were followed in 1595 by the Dutch, who soon eclipsed them. Though their views were at first directed wholly to commerce, the Dutch merchants, like the British East India Company, soon found it necessary to assume the position

of a governing power, and treated accordingly with the native princes, with whom they were frequently at war. In 1811 Java was taken from the Dutch by the British, who, however, restored it after the Peace of 1816, since which time it has remained in their hands. Up till 1825 various portions of the island were still under native princes, who paid tribute to Holland; but in that year a revolt took place, which resulted in the whole island falling under the Dutch sway; although two provinces have been left, but only nominally, under the government of Javanese princes—Surakarta and Jokjokarta. Both princes have a court, nobles, ministers, etc., but are the mere instruments of the Dutch government, by whom they are allowed handsome pensions. Since the close of this war the island has been rapidly increasing in population and prosperity. On 20 Sept. 1859 the Dutch legislature totally abolished slavery in Java. The natives never had slaves, and there never were but a few thousand on the island.

Language and Literature.—It is not certain whether the name of Java be connected with the Sanskrit Javana and Yavana, both of which, beside being related to *Iovia* as names of Greece, also signify (especially the latter) Bactria, Arabia, and other foreign countries, and, moreover, swift, horse, etc.; or whether its etymon be of a different origin. As regards the affinities of the Javanese language, Roorda considers it as a branch of the Malay. Crawfurd derives it from the vernacular of the aborigines, to whom he attributes the primitive culture of the Malayan islands. Domeny de Rienzi supposes it to have arisen from the language of the Bugis of Celebes, by an admixture of Malay and Sanskrit. Humboldt connects it, both as to words and grammar, with the Tagala, the most developed Malayan tongue of the Philippine Islands, as well as with other Malay idioms and with Sanskrit. Others see in it a type of the unmixed tribes of Oceania. It certainly shows all these affinities, and contains also some Arabic elements. The Javanese is the most cultivated of all Polynesian languages, owing to the very early intercourse of the island with the continent of India, whose Aryan as well as Dravidian influence is attested by the presence of Malabaric words along with those from the Sanskrit, not only in Javanese, but also in the idioms of Sumatra, Madagascar, etc. Both religious and political revolutions have served to modify the condition of the languages. There are four dialects, according to Raffles, on the three islands which form the linguistic group in question, namely: (1) The tongue of the mountaineers of Sunda, in the western part of Java, east of Tagal, probably vernacular through this whole region before the introduction of Mohammedanism, now spoken by about one tenth of the population of the island; it contains many Malay and some Sanskrit words, stands in the same relation to the principal language as the Welsh does to the English, and is best spoken at Bantam, sluggishly at Bogor and Chianjore, and verging to the Javanese at Cheribon. (2) The Javanese proper, east of the last named city, extending through the rest of the island, especially along its north shore; its words are long at Tagal, shorter at Samarang, full, short, and strong at the courts of Sur-

JAVA

karta in the centre, and Jokjokarta in the south; it approaches the Madurese at Surabaya, and the Balian at Banyu-Vangi. (3) The dialect of Madura and Sumanap, which has many Sunda words, with more of Malay, and with peculiar endings. (4) That of Bali, little different from the general Javanese. This island preserves the ancient letters as well as Brahminism, both expelled from Java in the 15th century. A sort of jargon, analogous to the *lingua franca*, is spoken at Batavia, being a medley of Dutch, Portuguese, Javanese, and Malay. Along with the preceding there are also peculiar styles or idioms of speech, varying in accordance with social position and age, as the *madhjo* (intermediate), between equals; the *basa* or *bohoso-ngoko* (language popular), to inferiors; the *basa-kromo* (language superior), urbane, court idiom, about three fourths of it Sanskrit, used by poets as the speech of gods, heroes, and ghosts. As to locality, there are also two vernacular idioms, namely, the *basa-dalam* of the interior, and the *basa-luar*, spoken along the shores. The Kavi (learned, wise, poet) is the ancient sacred language of Java, and consists of about six parts of Sanskrit, less altered than in the Pali, to four of Javano-Malay. It owes its origin to Brahminic immigration, about the beginning of our era. It is to the Javanese what Sanskrit is to the Hindostanee, and Pali to the Indo-Chinese languages. Declining in the 14th century, it took refuge in Bali, and was imperfectly known by the Panambahan at Sumanap at the time when Raffles was in Java. Passages in the Kavi are sometimes quoted on peculiar occasions, as for instance in fables and dramas; the term itself is employed as a title of works, etc., such as *Sekar-kavi*, flowers of poetry, whence *Sekarini*, a Kavi metre; *Rama-kavi*, the Javanese Rama-yana; *Kavindhra*, principal singer or poet (named *ma-kathā*, narrator, in Tagala). A few specimens of words may show the relation of the Javanese to the common Malay, where the difference, if not specially noted, is sometimes more in the accent than otherwise: *langit*, heaven; *tanah*, earth (Mal. also *benua*, region); *ayer* (Jav. also *banyu*), water; *laut* (Jav. *la-hut*), sea; *dhina*, (Mal. *hari*), day; *bengi* (Mal. *mālam*), night; *lulan* (Mal. *balan*), moon; *terang* (Mal. *trang*), light; *mati*, to die; *lulat* (Mal. *kāsih*), to love; *dara*, virgin; *dhēva* (Mal. *tuhan*), god, lord; *mangan* (Mal. *mākan*, *santap*), to eat; *bāpa*, *pak* (Mal. *pā*, politely *ayal*), father; *ma*, *bok* (Mal. *mā*, *amā*, politely *ibu*, *bonda*), mother, etc. Compounds and derivatives abound, but the latter are more frequently formed by suffixes than by prefixes, in which the Tagala is very rich. There are many contractions into *tr*, *ngr*, *ngr*, with the dropping of short vowels, together with the alteration of the initial sound (similarly to the Celtic), and other variations which obscure the etymic origin, thus: Sans. *nātha*, master, lord, becomes *tata*, order, to reign; Jav. *neda*, to eat, *teda*, food; *nulis*, to write, *tulis*, scripture; *nitik*, to prove, *titik*, proof. The prefix *n* denotes verbs, *t* substantives; other changes are: *nyatur*, to tell, *chatur*, tale; *nyerrat*, to write, *serrat*, writing, etc. The doubling of the first syllable makes verbs, as *tutulung*, to help, from *tulung*, aid; *gagriya*, to dwell, from *griya*, house. The

insertion of *in* is the sign of the passive voice. Substantives are also made by prefixing *pem* (*pen*, *pe*), denoting an agent; thus: *pem-pektō*, carrier, from *pektō*, to carry; *pem-dahar*, eater, etc.; by prefixing *ka*, a sign of the past participle; *ka-bektō*, Lat. *allatum*; by suffixing *n* (*en*, *an*): *bakt-en*, the carrying, *dahar-an*, Lat. *cibus*; and by both prefix and suffix: *ka-dahar-an*, an eatable. Articles, gender, and the dual number are wanting. In the plural, cases are denoted by particles, and also by reduplication, as in the Japanese. The genitive relation is shown by the precedence of the noun or by inserting *ing*. The other relations of case are indicated by means of verbs. The adjective is unchanged after the substantive. Pronominal forms are fewer than in Malay: *kita*, we in Malay, means I in Javanese. The numerals are: (1) *sidshi*, (2) *loro*, (3) *telu*, (4) *papat*, (5) *limo*, (6) *nem*, (7) *pitu*, (8) *volu*, (9) *songngo*, (10) *sepuluh*, (11) *savelas*, (12) *volas*, etc. Ordinals are formed by prefixing *ping* or *kaping*. The figures of numbers are modified letters. The person, number, tense, mood, and voice of verbs are indicated by certain particles. Many verbs and nouns are expressed by the same word, others are distinguished as stated above. The suffixes of the imperative are *o*, *ono*, *en*, *enno*. The following are examples of a verb in various forms: *ningngalli*, to see; passive, *dhipun*, *tingngalli*, *kattinggalan*, etc.; *kula*, *tingngalli*, I have seen; *bade kula tingngalli*, I shall see; *tinningngallam*, to see one another; *sampeyan tingngalli*, see; *kula tingngallana*, that I may see, etc. The construction is as follows:

*Rama kahula kang vonten ing surga, vasta andika dadi
Father our who art in heaven, name thy be
chapieno.*

As regards the shape and employment of letters, the graphic system is derived from the Devanagari, but not as regards their order, which is as follows: *'ha, na, tcha, ra, ka, da, ta, sa, va, la, pa, da, dja, ya, nya, ma, ga, ba, ia, ng'a*. These 20 *Akshara* (letters) are consonants with an adherent *a* in the general language, or *o* at the courts of princes, which, when not suppressed, gives to the syllabarrium the epithet of *lagana*. As many *Pasangan* (consonants) are vowelless, three of them are annexed, the others subscribed to other letters. This peculiar succession of letters must have originated prior to that of the organic scheme of the Devanagari, and it is explained by its signifying: "There were two messengers, disputing, equally courageous, till both died." The *Akshara-Buddha*, being ancient, differ in form from the later *Akshara-gede*. Some Kavi letters are almost like those of the Sanskrit, while the more recent resemble the square Pali. The vowels are called *San-dang'an* (connection), namely, *a*, *i*, *u*, *ɛ*, *ɔ* (almost French *œuf*), *o*, either used as initials or (except *a*) attached to the consonants instead of the inherent *a*. The diacritic signs are analogous to those of the Devanagari. There are also characters for the quasi-vowels *le* and *re*. The writing runs from left to right, each letter being connected with the others in words, and these following one another without any space left between them. Tradition assigns the introduction of writing as well as of Brahminism

JAVA ALMOND — JAWS

and political institutions to Aji Saya Baya. Palaeography finds a rich harvest in Java, its subjects being distributed in four classes: (1) inscriptions in ancient Devanagari near the ruins of Brambanan and Sinagasari; (2) those in square Kavi letters, from which the cursive are derived, mostly on stone and metal; (3) those in a dialect resembling the language of Sunda; (4) the *Chandra-Sangkala* (light of royal times or dates), which consist in selecting such words, symbolic of numbers, as may also express a fact that is to be recorded. Thus, for instance, the date of the destruction of Majapahit, a fact most important in Javanese history, is thus inscribed (1400, reading from right to left):

Sirna (o) ilang (o) kertaning (4) bumi (1)
Lost and gone (is) (the) work, (pride of the) earth (land.)

The date of certain long graves at Gresik, near the tomb of the princess of Chermai (1313), is thus written:

Kaya (3) vulan (1) pütri (3) iku (1).
Like (to) the moon princess (that) was.

The literature, which is in Kavi, dates from about the commencement of our era, and is rich, especially in legends concerning cosmogony. The subjects of the works are mostly either of a mythical or ethical character. Prominent among the former are: the *Kanda* (Sans. *Khandata*, fragment, section) *Pepakem* (book), or *Sejarah* (history); *Manek-Maya*, a mythical genesis, in which Buddhism predominates; *Vivaha-Kavi* (matrimonial poem), about a *Rasaksa* (evil spirit) who courts a *Vidaduri* (nymph); *Rama-Kavi*, the Javanese *Ramayana*; *Parikesit*, "Arjuna's Grandson"; *Mintaraga*, a poem on Arjuna in the Indra mountain. This kind of composition comes down to the time of Aji Saya Baya. Of the ethical order are the *Niti Sastra Kavi*, in the purest style, of about the 13th century; and *Sruti*, which already alludes to Islam. But the *Brata Yudha* ("Holy War") is an epos mostly on the deeds of Arjuna; being an episode of the *Mahabharata*, in 712 stanzas, with varying rhymes. The *Sastra Menara* is a Javanese imitation of the ordinances of the Indian *Menu*. Indeed, most of the Kavi works are such imitations. Whether mere versions of Sanskrit works have been made or still exist is not precisely known; but there are many Javanese versions from the Kavi. Javanese literature abounds in romantic compositions, mostly of elegiac form. Among these, the adventures of the popular hero Pandji are most prominent. Dramas, and especially puppet shows, called *vayang* (shadows), and with figures of either leather or wood personating heroes, are popular.

Java Fowl. See POULTRY.

Java Sea, a body of water with Borneo on the north, Celebes on the east, the island of Java on the south, and Sumatra on the west. It borders on a number of other islands, all small. The direct route from Singapore to Australia is through Java Sea; and it is crossed by two approved routes to China, one by Pitt's Passage and the other through the Straits of Macassar.

Java Sparrow, a species of Oriental weaver-bird (*Munia oryzivora*), called rice-bird or paddy-bird by the British in India and China, where it has become naturalized from its original home in Java. It has a poor song but is kept in cages for its beauty and liveliness, and is sold by bird-dealers all over the world. Its colors are slate-blue and black, with conspicuous white cheeks and a swollen rosy bill.

Javary, zhā-vā-rē', a river which has its rise in the northwestern part of Bolivia, flows northwest, then north and northeast into the Amazon River. The greater part of its course of 350 miles, it forms the boundary line between Brazil and Peru. It is navigable from the mouth to the Anahuac Mountains. By treaty between the governments of Brazil and Bolivia, the source of the Javary is the demarcation of the boundary line between the countries.

Javelin, a short and light spear thrown from the hand, and in ancient warfare used by both horse and foot soldiers. The *pilum* of the Romans was a weapon of this description, and was used either to throw or to thrust with. The shaft was 4½ feet long, and the barbed iron head was of equal length, but as it extended half way up the shaft, the whole length of the weapon was nearly 7 feet. The shaft, made of some tough wood, often cornel, was an inch in diameter. The use of the javelin was not confined to the Roman legionaries, for many barbarous tribes, and especially the Goths, employed this weapon in their military operations.

Jaws, Anatomy of the. The upper jaw is formed by the union of the two superior maxillæ; these bones each form part of the cheek, the outer wall of the nasal cavity, the hard palate, and the lower part of the eye-socket. The lower jaw is formed of one bone, the inferior maxilla, which presents a horseshoe-shaped body, and vertical plates of bone ascending from the body posteriorly. The top of these vertical plates is widened into a knob-like end for articulation with the skull.

Dislocation of the jaw may take place during excessive laughter or yawning. The articular knob slips forward and the jaw is held open. Reposition is accomplished by placing the thumbs on the back teeth and making forcible downward and slightly backward pressure until the bone is felt to snap into place.

Fracture of the upper jaw is uncommon except when the face is crushed in. Usually in fracture it is the body of the lower jaw near the front that is broken. Besides the usual signs of fracture (q.v.) the attitude may be character-

JAXARTES — JAY

istic; the patient is unable to shut the jaw; and the difference in the line of the teeth may show clearly. Repair of the fracture is facilitated by fastening the upper jaw with a sling-bandage carried around the head, and keeping it so fastened until union is established. During this time the patient is forced to eat liquid foods almost entirely.

Jay, John, American statesman and jurist: b. New York 12 Dec. 1745; d. Bedford, Westchester County, N. Y., 17 May 1829. His father was a wealthy merchant of Huguenot stock, and his mother a daughter of Jacobus Van Cortlandt. His father,—early discovering, to use his own words, that Jay was of "a very grave disposition, and took to learning exceedingly well"—sent him to a school in New Rochelle something like Dotheboys Hall in 'Nicholas Nickleby.' Three years at school were followed by study under a tutor until he entered King's College at 14. He was graduated in 1764, the subject of his oration being the blessings of peace, of which he was to have still keener appreciation. Two weeks later, on payment of £200, he entered the office of Benjamin Kissam, a prominent lawyer of New York, as an apprentice bound to serve five years, the last two years to be devoted to the study of the law. Admitted to the bar in 1768, he soon attained prominence in the profession, forming a partnership with Robert R. Livingston, afterward chancellor of the state, and secretary of foreign affairs. In 1773 he began his public career, as secretary to the Royal Commission to determine the boundary between New York and Canada; and for the following 28 years his public services were constant, varied and of supreme importance to the country so fortunate in being his birthplace. All his duties in the many fields covered by him during his splendidly successful life were performed in a manner indefatigable, zealous and faithful, and with marked ability.

Bound by no ancestral ties to England, and having married in 1774 a daughter of the famous Whig, and Revolutionary Governor of New Jersey, William Livingston, many would suppose that in the conflict impending between the colonies and mother country, Jay's voice, like those of James Otis and Samuel Adams, would have been from the first "still for war." But he was constitutionally so calm and conservative that he was unwilling to be too precipitate in determining upon a change in the mode of government. When, however, the colonists decided that their only safety lay in separation, Jay was found to be as staunch and aggressive a patriot as any, and represented the citizens of New York on the committee to settle the question arising out of the Boston Port Bill. Jay drafted the suggestion of that committee that "a Congress of Deputies from the Colonies in general" be convoked—in fact, the convocation of the Continental Congress. He was a member of that congress, and met with it in Philadelphia on 5 Sept. 1774. Congress at once appointed a committee to "state the rights of the colonies in general," of which Jay was made a member. This committee designated him to draft an address to the people of Great Britain, which was so satisfactory that it was at once reported to Congress, and adopted by it. Jefferson, without knowing who was the author, pronounced it "a

production certainly of the finest pen in America."

Jay was also sent to the 2d Continental Congress, but in the interim devoted himself to shaping the public mind in the direction of obedience to Congress and in hostility to enforcement of Parliamentary taxation. When the 2d Congress convened, the signal shot—"heard round the world"—had been fired at Lexington, and Congress, realizing that a condition of war existed, deputed Jay to draft an address to the people of Canada, which was prepared and adopted, and circulated in that country. He also wrote an address to the people of Jamaica and Ireland by request of Congress, but the second petition to the King that he prevailed upon Congress to make was written by Dickinson. Other important and effective work by him in that general direction might be cited, but I shall be content with the assertion I deem supported by the facts, that as a creator and molder of public opinion at that particular juncture Jay stands unrivaled; and all this was in the main accomplished through the wise use of his pen, the efficacy of which was strongly presented by John Adams when he wrote regarding it to Jefferson, "I never bestowed much attention to any of those addresses, which were all but repetitions of the same things; the same facts and arguments; dress and ornaments rather than body, soul or substance. I was in great error, no doubt, and am ashamed to confess it, for these things were necessary to give popularity to the cause, both at home and abroad." Jay's contribution to the debates in Congress, like all his public work, showed that he followed in all things and upon all questions the path illuminated by the light of his well balanced judgment, and his conscience, thinking not of personal popularity, but simply of the right. He served actively upon the committee that carried on negotiations with foreign powers friendly to America and inimical to England. Indeed, during the year 1775 he was a member of so many committees, each having different and important objects, that it is difficult to understand how he was able to accomplish so much important and laborious work.

If it be asked why so good a patriot as Jay was not a signer of the Declaration of Independence, the answer is, that in 1776, while a member of the Continental Congress, Jay was also elected to the New York Provincial Congress, and the Continental Congress having directed the colonies to each adopt a government, Jay, on the call of his colony, proceeded to New York to take part in the formation of the local government, where he was forced to remain while the Declaration of Independence was being signed. During 1777, and while the war was going on in the vicinity of New York, the Provincial Congress, then styled the Convention of the Representatives of the State of New York, was laboring with exceeding difficulty, the members, as is recorded, performing "all the various and arduous duties of legislators, soldiers, negotiators, committees of safety and ways and means, judges, juries, fathers and guardians of their own families, flying before the enemy, and then protectors of a beloved commonwealth." Yet amid all this turmoil and unrest a constitution was drafted by Jay which was, in the main, adopted as drafted, and was published upon 22 April 1777, by being read in front of

JAY

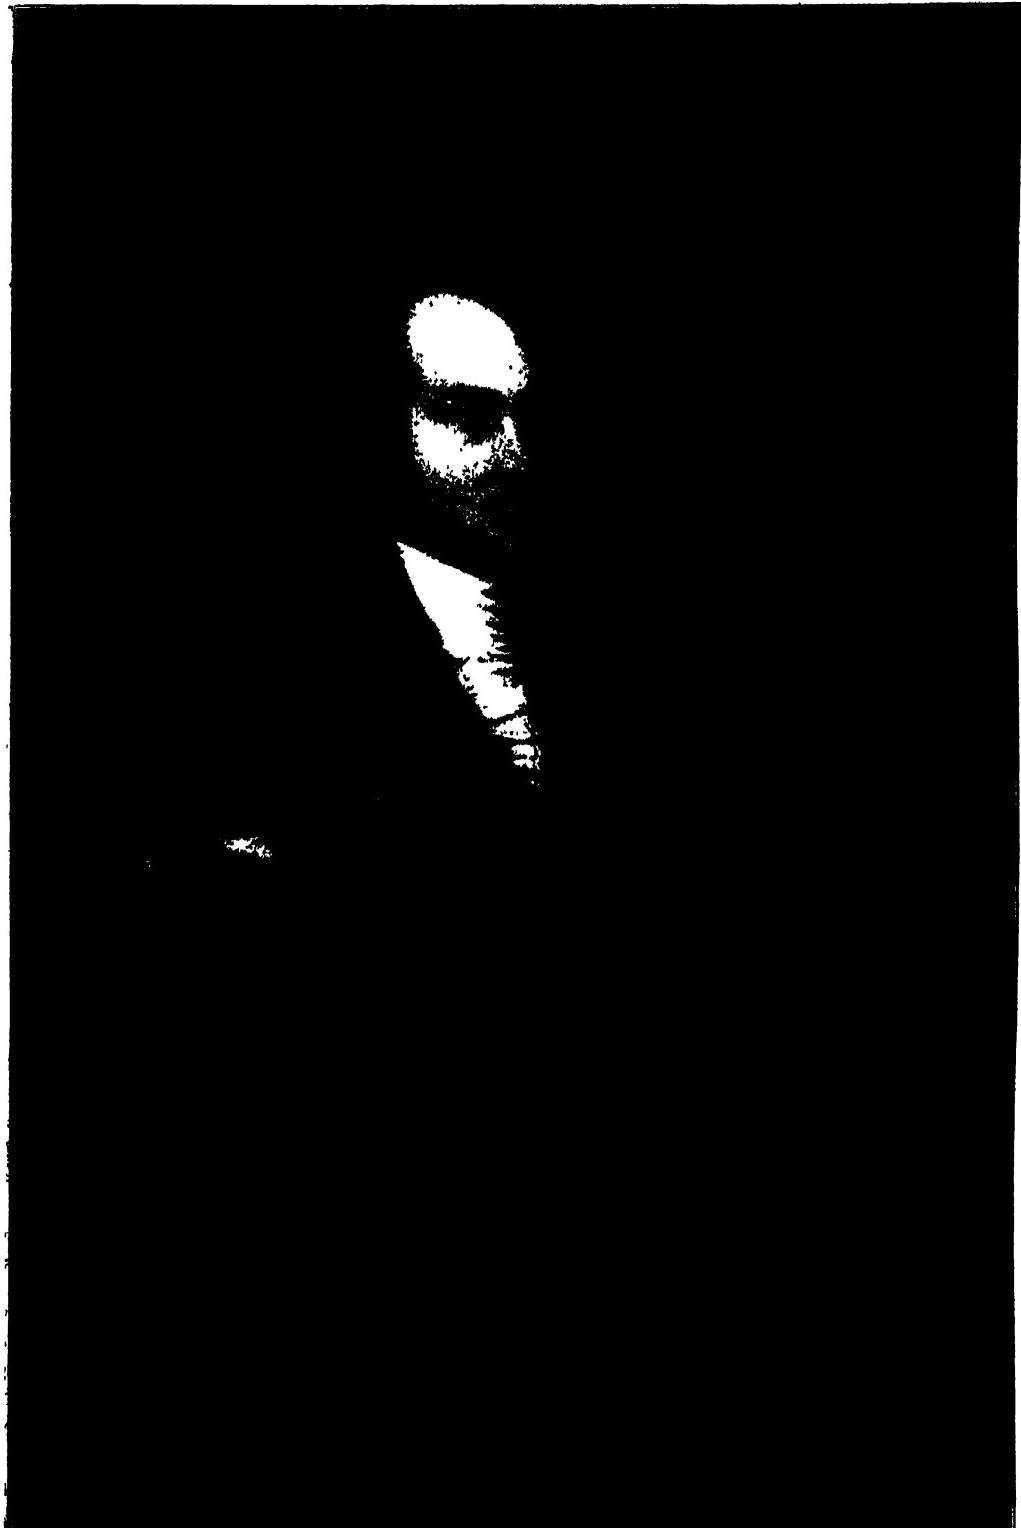

the court-house in Kingston. A committee was at once appointed, Jay being a member, to organize a new government; and a council of safety was created to act until the legislature should meet. Robert R. Livingston was appointed chancellor and Jay chief justice, and the judicial department of government was temporarily organized.

Jay was urged to be a candidate for governor at the first election under the Constitution, but declined. General Clinton was elected over his opponent, General Schuyler, and took the oath of office, it is said, while "clothed in the uniform of the service, standing on the top of a barrel in front of the Court-House in Kingston." On 9 September following, Chief Justice Jay delivered an address to the grand jury at Kingston, which is to be found in the first volume of his correspondence and public papers. The address is a much prized document of revolutionary times, and was, undoubtedly, intended to reach and affect a much larger constituency than the grand jury to whom it was delivered. Of course, in those unsettled days, with the struggle between the old and the new countries raging, but little litigation of importance came before the supreme court, so that during Jay's chief justiceship the work of the court was mainly confined to criminal trials, and the court never sat in banc. During 1778 he was active in the Council of Revision, of which he was a member ex-officio. The legislature in 1779 appointed Jay to Congress without requiring him to vacate the office of chief justice, it being resolved that owing to serious questions between certain States "a special case" obtained under the Constitution. Shortly afterward Congress elected him its president. Later in the year, however, he resigned the office of chief justice, designing, he said, to recoup his failing fortunes. But his desires in that direction were not to be gratified. More than 20 years elapsed before the public he had served so well would submit to be deprived of his services.

In October, 1779, Jay resigned the presidency of Congress to accept the office of minister to Spain. His instructions in part were to secure if possible a commercial treaty with Spain similar to that existing with France, to acquire a port in Spanish dominion on the Mississippi, and to negotiate a loan of \$5,000,000. That his mission was not entirely successful, and was personally disagreeable, was due to the fact that Spain disliked the new nation because it occupied lands formerly held by Spain, and it was apprehended that with increasing strength it might reach out and take more—fears that we know now were not groundless. While minister to Spain, Jay was appointed, with Franklin, Jefferson, Adams, and Laurens, commissioner for a general peace. Their instructions rested on the mistaken theory that France would aid in procuring for us the best possible terms. In June, 1782, Jay joined Franklin, then minister to France, in Paris, and promptly but cautiously entered upon an investigation which disclosed that France had other interests to serve than those of the United States. Possessed of the situation, he boldly entered upon negotiations with England's representative without even consulting his only colleague in Paris, whom he regarded as necessarily embarrassed by his position as minister to France, and his instructions. With firmness, and yet with great tact, he con-

ducted the negotiations alone until joined by Adams, who enthusiastically approved of his action, and so advised Mr. Franklin, who, after consultation, agreed that the negotiations should be concluded without consulting the French court. The result of these most interesting negotiations with England was a treaty by which the United States gained more than Congress had ever ventured to propose. And Jay's part in this great triumph of diplomacy is well summed up in a letter written by his fellow commissioner John Adams to Jonathan Jackson, "a man and his office were never better united than Mr. Jay and the commission for peace. Had he been detained at Madrid, as I was in Holland, and all left to Franklin, as was wished, all would have been lost." When he returned New York gave him the freedom of the city in a gold box, and he found that he had been appointed by Congress secretary of foreign affairs. This office he filled with his usual ability, settling international questions, and advocating the building of a navy, and the organization of a federal government under a constitution. His papers in the *'Federalist'* evidence both his activity and forcefulness in this direction, and his influence contributed in no small degree in bringing New York to the support of the Federal Constitution.

It is said that after the first election of Washington to the presidency he offered Jay the choice of any office in the government, and that he chose that of chief justice of the Supreme Court of the United States, which he justly regarded as the most exalted position next to the presidency; but be that as it may, Washington appointed him to that position, and in his letter to Jay, advising him of the nomination, said, "I not only acted in conformity with my best judgment, but I trust I did a grateful thing to the good citizens of these United States." The opportunity to contribute largely toward the development of the law in this country did not come to him, however. Had it, his success in other fields and his well poised mind assure us that Washington's judgment would have been triumphantly vindicated. Only a few causes came before the court during his incumbency, and the record of those, with a single exception, are preserved only in the minutes of the clerk, but his every step was in the right direction, whether taken while holding a circuit or sitting in banc with associates, and had effect in shaping the foreign policy of the United States as well as in establishing the dignity and independence of the Federal judiciary. He continued to hold the office until he resigned in 1795; but in the meantime and in 1792 the Federalists supported him unsuccessfully as against Governor Clinton for the governorship of New York, and in 1794 President Washington urged him to go to Great Britain as special envoy to settle differences growing out of the failure of that country to keep the obligations of the Treaty of 1784; differences which had aroused a strong war spirit all over the land. It was easy to foresee, as Jay foresaw, that the outcome of the situation would in all probability be unpopular with the people, but he did not hesitate to meet the responsibility that Washington believed he could meet better than any other man, partially because of the reputation he had established in England while negotiating the Treaty of Peace of 1784. A treaty

Copyright by C. E. Anderson, Sec'y, 1901.

JOHN JAY.

CHIEF JUSTICE OF THE UNITED STATES SUPREME COURT, 1789-1795.

JAY

resulted, known on this side of the ocean as "Jay's Treaty," which settled the eastern boundary of Maine, recovered for illegal captures by British cruisers \$10,000,000, secured the surrender of the Western forts still garrisoned by the British, and contained an article about the West India trade. With the exception of the latter article the treaty was approved by the President and ratified by the Senate. But many were not satisfied, and they denounced him with tongue and pen, and even burned him in effigy in Boston, Philadelphia and at his own home, New York. How different was the homecoming from that after the negotiation of the other treaty, when the freedom of the city was presented to him in a gold box, and each one seemed to vie with every other in extending a welcome. In a letter to a friend, Jay said at that time, "Calumny is seldom durable, it will in time yield to truth"; and he bore himself at that time as one having full confidence that he had acted both wisely and skilfully, and expected the people to realize it in time.

He found on his return that he had been elected governor of New York—before the public had knowledge of the terms of the treaty, of course. Before the close of that term, and in April 1799 he was re-elected by a majority so large as to constitute a personal triumph. During this term the statute was passed providing for the gradual emancipation of slaves within the State, then numbering about 22,000. The six years of his incumbency of the office of governor were crowded with interesting legislative and executive events in which he performed his part with that staunch devotion to the public interests which ever characterized his efforts throughout his career as a servant of the public, as is well illustrated by his refusal to be a party to the scheme of certain leaders of the Federalists to secure the electoral vote of New York for the ensuing election. The unexpected result of the spring elections of 1800 assured the Republicans of a substantial working majority on joint ballot, and hence of the Presidential electors under the law as it then stood. It was generally conceded that New York would determine the choice of the next President. Although the Federalists had, in March prior to the elections, defeated the attempt of the Republicans to redistrict the State, and had insisted that it was necessary that the State should act as a unit in the choice of Presidential electors, the leaders changed their position after the election had gone against them, and insisted that the electors should be chosen by districts. Alexander Hamilton wrote Governor Jay on 7 May advising that he call an extra session of the Legislature to enact such a statute before July first, the end of the legislative year. Philip Schuyler also wrote a letter strongly urging that such a course furnished the only means of saving the "nation from more disasters." But Jay, although a staunch Federalist, who had received the votes of New Jersey and Delaware, five votes from Connecticut and one from Rhode Island for the Presidency in the preceding electoral college, refused to take such action, and endorsed on Hamilton's letter these words: "Proposing a measure for party purposes which I think it would not become me to adopt." He refused a renomination for the office of governor on the ground that he now intended to retire from public life, and his purpose was

unshaken by President Adams announcing to him his nomination and confirmation a second time as chief justice of the United States.

For 28 years he had been a good and faithful public servant. To him indeed had public office been a public trust, in which he had toiled faithfully and intelligently, having only in view his duty and the public good, unmoved by desire for great emolument or popularity. Naturally conservative he carefully examined every situation before acting, but when he had determined the proper course to take he acted promptly and boldly, and without regard to the effect of his course upon himself. His perfect self poise had its effect upon associates and subordinates, and the value he placed upon it may be inferred from his letter of instructions to William Carmichael in which he said, "Command yourself under every circumstance; on the one hand avoid being suspected of servility, and on the other let your temper be always even and your attention unremitting." This great patriot gave to the public service the day of his vigorous manhood, the best years of his life, covering the period of the struggle for independence and the formation of our complex system of government, the years when his country most needed the faithful service of her sons. He set aside every personal interest, laboring with fidelity and unselfish effort, and showing himself willing to "spend and be spent" for his country. Having borne his portion of travail at the birth, and done his part in the nurture of the early infancy of this great nation, he retired at last to his farm at Bedford, Westchester County, where he lived a restful life, indulging his agricultural, philanthropic and religious tastes, and enjoying the confidence, esteem and affection of the people until he went to his last rest at the age of 84 years, leaving behind him

"A name that shall live through all coming time,
Unbounded by country, by language, or clime."

Consult: 'Correspondence and Public Papers of John Jay' edited by H. C. Johnston (1890-3); William Jay, 'Life of John Jay' (1833); White-locke, 'Life and Times of John Jay' (1887); Pellew, 'John Jay' (1890).

HON. ALTON B. PARKER, LL. D.,
*Chief Judge of the Court of Appeals of the
State of New York.*

Jay, John, American diplomatist: b. New York, 23 June 1817; d. there 5 May 1894. He was the son of William Jay (q.v.) He was graduated from Columbia in 1836, studied law in New York, was admitted to the bar in 1839, became a prominent opponent of slavery, was secretary of the Irish relief committee in 1847, and was counsel for several fugitive slaves. He organized the meetings at the Broadway Tabernacle, New York, in 1854, and took a leading part in the organization of the Republican party at Syracuse 27 Sept. 1855. From 1869 until his resignation in 1875 he was United States minister to Australia, in 1877 was appointed chairman of the so-called Jay commission for the investigation of the New York customs-house administration, and in 1883 was appointed the Republican member of the New York State civil service commission. He was long corresponding secretary of the New York Historical Society, and published several pamphlets, among them: 'The Dignity of the Abolition Cause' (1839); and 'The American Church and the American Slave-trade' (1860).

JAY — JAY'S TREATY

Jay, William, English Congregational clergyman and writer: b. Tisbury, Wiltshire, 8 May 1769; d. Bath, 27 Dec. 1853. After studying for the Congregational ministry, he officiated at Hope chapel, near Bristol, and became pastor in 1789 of Argyle chapel, Bath, where he remained till 1852. As a preacher he not only enjoyed a high celebrity in his own denomination, but won the applause of critics like John Foster, Sheridan, and Beckford. His published sermons are esteemed as well for their catholic spirit as their practical earnestness and simplicity of style. They have passed through many editions, and besides them he wrote 'Essay on Marriage'; 'Lectures on Female Scripture Characters' (1854); 'Morning and Evening Exercises' (1854). His autobiography, in the form of letters, appeared in 1854.

Jay, William, American jurist: b. New York, 16 June 1789; d. Bedford, N. Y., 14 Oct. 1858. He was the son of John Jay, statesman and jurist (q.v.). Graduated from Yale in 1808, he studied law with J. B. Henry at Albany, was obliged by defective eyesight to withdraw from the profession, and became interested in various philanthropic movements, including the anti-slavery cause. He was a founder of the American Bible Society (1816), which he greatly promoted and long defended against High Church attacks led by Bishop Hobart. In 1818-21 he was judge of common pleas in New York, and in 1835-7 corresponding foreign secretary of the American Anti-Slavery Society, in the drafting of whose constitution he had assisted. He wrote much on anti-slavery, and was recognized as a leader of the more conservative of the Abolitionists. Among his publications were: 'The Life and Writings of John Jay' (1833); 'An Inquiry into the Character and Tendency of the American Colonization and American Anti-Slavery Societies' (1834); 'A View of the Action of the Federal Government in Behalf of Slavery' (1837); 'War and Peace' (1848).

Jayhawk, a name originating in Kansas during the slavery and anti-slavery warfare; applied to a few Free State men who organized a system of retaliation against pro-slavery outrages. Gov. Lane of Kansas, in 1861, declared that "the people of Kansas were neither thieves, plunderers, nor jayhawkers."

Jays, a group of birds forming with the magpies a sub-family (*Garrulinae*) of the *Corvidae*, or crow family. They are readily distinguished from the true crows (*Corvina*) by their relatively short wings, long conspicuous tails, and usually showy plumage, in which blue colors are prominent. They are generally smaller than the crows, have weaker bills, and feet better adapted to the more completely arboreal life which they lead. Jays are found throughout the greater part of the world, but America leads in number and variety of species. North America has four genera and ten species with many additional local varieties. A familiar representative is the bluejay (*Cyanocitta cristata*), which is numerous throughout the eastern half of the United States and Canada. It is about one foot long, of which the tail is nearly half; the head conspicuously crested; purplish-blue above with a slight tinge of the same color on the generally gray underparts; the wings and tail are a

nearly saturated blue in the males, duller in the females, cross-barred with black and with white markings especially conspicuous on the end of the tail; a rich black collar encircles the neck. The bluejay eats all kinds of nuts, fruits, large insects, and at times the eggs and young of other birds; it seldom leaves the trees in search of food, and when on the ground hops instead of walking like the crow. Except in Canada it is resident, and it breeds throughout its entire range. The nest, a large structure of twigs, grass, leaves, etc., is built in trees, bushes, or old buildings. Five is the usual number of eggs. Like the magpie this jay is known to collect and hoard various glittering or brightly colored objects, but is chiefly noteworthy on account of the variety and quality of its notes which range from the harshest cries to full flute-like tones. On the Pacific Coast this species is replaced by the darker and duller Steller's jay (*C. stelleri*). The Canada jay, or whiskey jack (*Perisoreus canadensis*) is, as its name indicates, a northern bird, found within the United States only along the northern border, and occasionally breeding in northern Maine. This is a dull-colored gray bird, without a crest, and with soft, lax plumage. It is well known to hunters and lumbermen whose camps it haunts with great boldness; and in manners and voice resembles the bluejay. It nests very early in the spring. Related species are the Oregon jay (*P. obscurus*) and the Siberian jay (*P. infaustus*) of boreal Eurasia. Several species of crestless deep-blue "Florida" jays (*Aphelocoma*) inhabit Florida and the west and the southwest. The brilliant green jay (*Xanthura luxuriosa*) is an example of the gorgeous tropical jays which just enter the United States in Texas. Consult the works: Wilson, Audubon, Nuttall and American ornithologists generally; for western species in particular, Coues, 'Birds of the Northwest' (1874), and 'Birds of the Colorado Valley' (1878).

Jay's Treaty, 1794. The Articles of Confederation provided that the States might nullify at will any provisions of whatever commercial treaty Congress might negotiate; of course therefore no nation with much commerce to be disturbed by our competition would make such treaties with us. Our chief commerce was with Great Britain; and that country would make no commercial treaty whatever with us, even for years after the Constitution had given Congress power to enforce its treaties. There were two main reasons for this: first, that Great Britain had valuable commercial monopolies (especially in the West Indies) for which she thought we could return no equivalent; second, she was angry over the *sequela* of the peace of 1783. She had agreed to surrender the border forts on the Great Lakes, the St. Lawrence, and Lake Champlain, and carry off no negroes, on condition that Congress "recommend" to the States to restore confiscated Tory property, and agree to confiscate no more. Congress did so twice emphatically, but the States paid no attention to it; the British government, though it knew very well how much the recommendation meant, made this an excuse to retain the forts and refuse payment for 3,000 negroes carried off; this in turn hardened the States to refuse compliance with the treaty, and the forts being

THE JAY FAMILY.

1. European Jay (*Garrulus glandarius*).
2. Mexican Long-crested Jay (*Cyanocitta diademata*)
3. Canada Jay (*Perisoreus canadensis*).
4. Blue-capped Jay (*Cyanocorax chrysops*).
5. American Bluejay (*Cyanocitta cristata*).
6. Spanish Jay (*Cyanopica cooki*).
7. Red-billed Jay (*Cissa erythroryncha*).

JEAN PAUL—JEFFERSON

made a basis for Indian outrages winked at by the British commandants enraged the country still more. The Republicans, who sympathized with the new French Republic and hated Great Britain, held the House; the Federalists, whose sympathies were exactly opposite, the Senate by a small majority. On 16 Dec. 1793, Jefferson made a famous report on a House resolution, recommending retaliatory duties; and after an acrid debate the Republicans pushed through a non-intercourse resolution, only defeated even in the Senate by Vice-President Adams' casting vote. But Washington threw his weight into the scale of peace, and nominated Chief Justice John Jay as envoy extraordinary to negotiate a commercial treaty. With Lord Granville he drew up one on 19 Nov. 1794, which removed the chief American grievance by surrendering the forts, but refused compensation for the negroes and referred all other claims to commissioners; and as to commerce, allowed direct but not coasting trade between the United States and the British East and West Indies (the latter in vessels of not over 70 tons), but denied the United States the right to export sugar, molasses, coffee, cocoa, or cotton to Europe—in other words, to become an intermediary for the British colonies to evade the British commercial monopoly; and limited even this provision to two years after peace with the powers then at war with Great Britain. There were also clauses which impliedly recognized British right of search and impressment, and power to make anything contraband. The treaty was ratified by the Senate in secret session (8 June 1795), but when published excited an uproar of public indignation; Jay was burned in effigy, and even Washington vilified incredibly. The Virginia legislature and the Federal House practically passed votes of censure; but the people gradually came to recognize that it was the best thing to be had, hard as were the terms; the commercial bodies in the States openly commended it; Hamilton wrote his "Camillus" letters in its favor; and after a bitter struggle for many weeks in the House to refuse compliance with the Senate action, the treaty won by 51 to 48.

Jeanne d'Arc, zhan dark. See JOAN OF ARC.

Jeannette, jén-nét'. Pa., borough in Westmoreland County; on the Pennsylvania railroad; about 22 miles southeast of Pittsburg. The natural gas which supplies the borough has contributed somewhat to its development. It is situated in a fertile agricultural region, which is also a coal mining section. The government is vested in a burgess, who holds office three years, and a council. Pop. (1890) 3,296; (1900) 5,865.

Jeannette Expedition, an enterprise, projected 1879 by James Gordon Bennett of the New York *Herald*, who sent out an Arctic expedition from San Francisco in the steamer Jeannette, under command of Lieut. De Long, U. S. N. The Jeannette was early caught in the icepack, drifted for nearly two years, and never escaped from its grip. After the wreck of the Jeannette the crew embarked in two cutters and a whaleboat. Lieut. Danenhower and a portion of the Jeannette's crew reached New

York in May 1882. The bodies of De Long and his men were finally discovered in the snow, with evidences that all had perished from cold and hunger. See POLAR RESEARCH.

Jepp, Sir Richard Claverhouse, English Greek scholar: b. Dundee, Scotland, 27 Aug. 1841. He was educated at the Charterhouse, London, and Cambridge University, and in 1869 became public orator of that university. In 1875 he was called to fill the Greek chair in Glasgow University, which he resigned in 1889, on being appointed Greek professor at Cambridge. He has several times visited the United States, and in 1874 married the widow of a general in the United States army. He was lecturer at Johns Hopkins University, Baltimore, in 1892. His best-known works are: "The Attic Orators" (1876); "Modern Greece" (1880); a "Life of Richard Bentley" (1882); "Homer: an Introduction to the Iliad and Odyssey" (1886); "Lectures on Greek Poetry" (1893); "Humanism in Education" (1899); and an edition of Sophocles, with notes and translation. Since 1891 he has represented Cambridge University in Parliament. He was knighted in 1900.

Jefferson, jéf'er-són, Charles Edward, American Congregational clergyman: b. Cambridge, Ohio, 29 Aug. 1860. He was graduated from Ohio Wesleyan University (Delaware, Ohio) in 1882, from the School of Theology of Boston University in 1887, was ordained to the Congregational ministry in 1887, and became pastor of the Broadway Tabernacle, New York. Among his writings are: "Quiet Talks with Earnest People in My Study"; and "The Broadway Tabernacle of the Past and Future" (1901).

Jefferson, Joseph, American actor: b. Philadelphia 20 Feb. 1829. He was privately educated and was early upon the stage, among his first public appearances being that as a miniature of T. D. Rice in one of the latter's "Jim Crow" entertainments at Washington, D. C. In 1843 he became a member of a band of strolling players that gave primitive entertainments through Mississippi and Texas, and followed the United States army into Mexico. On his return to the United States he appeared at the Arch Street Theatre, Philadelphia, directed the performances at Peale's museum in that city, became known as an excellent stock actor, and in 1851 played Marroll in "A New Way to Pay Old Debts" to the Sir Charles Overreach of Junius Brutus Booth. His prominence began with his creation of Asa Trenchard in "Our American Cousin," in which part he first appeared 18 Oct. 1858, and which eliminated from the stage the traditional caricature of Yankee character. He later appeared in the parts he has since made famous: Newman Noggs in "Nicholas Nickleby"; Caleb Plummer in "The Cricket on the Hearth"; Dr. Pangloss in "The Heir at Law"; Dr. Ollapod in "The Poor Gentleman"; Mr. Golightly in "Lend Me Five Shillings"; Salem Scudder in "The Octoroon"; Bob Acres in "The Rivals"; and, above all, Rip Van Winkle in the play of that name. Dissatisfied with his own dramatization of Irving's sketch, in which he had appeared at Washington in 1860, Jefferson had the play re-written by Dion Boucicault, and in Boucicault's version, with slight changes,

JEFFERSON

has since acted. The drama ran for 170 nights at the Adelphi, London, in 1865, and in the United States was so successful that for years Jefferson appeared there in nothing else. Jefferson's Rip long since established itself as one of the classic creations of the stage, and outside of Shakespeare probably no character has attained so wide and permanent a recognition among the American public. Of late years he has played but a few weeks annually in a repertoire of favorite parts. He also made a considerable reputation as an artist by his impressionist landscapes in oils. His acting method is distinguished by ease, verisimilitude, and perfection of finish. In the plays used by him he has, for artistic purposes, introduced several admirable changes and additions. He published an interesting *'Autobiography'* (1890); and a *'Reply to Ignatius Donnelly on the Shakespeare-Bacon Argument.'* Consult the *'Autobiography,'* and Carroll, *'Twelve Americans'* (1883).

Jefferson, Thomas, American statesman, third President of the United States: b. Shadwell, Albemarle County, Va., 13 April 1743; d. Monticello, Albemarle County, Va., 4 July 1826; student at William and Mary College, Williamsburg, Va., 1760-2; student of law 1762-7; member of House of Burgesses 1769-74; member of Virginia Conventions 1774 and 1775; of the Continental Congress 1775-6; of Virginia Legislature 1776-9; governor of Virginia 1779-81; member of Congress 1783-4; minister to France 1784-9; secretary of state 1790-3; Vice President 1797-1801; President 1801-9; in retirement at Monticello 1809-26.

Early Life.—Thomas Jefferson was the son of Peter Jefferson, a planter of Albemarle County, Va. His mother was Jane Randolph, daughter of Isham Randolph, who was a descendant of William Randolph of Turkey Island, the progenitor of that family so well known in Virginia history. Jefferson's birthplace was Shadwell, about four miles from the city of Charlottesville. At this homestead he resided until it was destroyed by fire in 1770; thereupon Jefferson selected a low mountain about two miles from Charlottesville, where he built that now famous mansion, "Monticello." Albemarle County, Va., has the proud distinction of being the section in which Jefferson was born, reared, lived, died and lies buried. Jefferson's early education, as was usually the case with Virginia planters, was entrusted first to a private tutor, from whom he learned Latin, Greek, French, and mathematics. At 14 his father died, and after two years in a school conducted by the Rev. James Maury, he entered in 1760 William and Mary College, at that time the best institution of learning in America. The student Jefferson is described as tall and raw-boned, with reddish hair and grayish hazel eyes. He was not then regarded as handsome, though in after years he was considered as probably the most attractive in appearance of the great Virginia statesmen. As a youth he was noted for his intelligence, and while at college, he was in constant association with such men of culture as George Wythe (q.v.), the eminent lawyer; Professor William Small, the profound scholar, and Governor Francis Fauquier (q.v.), the gay and accomplished gentleman. With these gentlemen, many years his senior, he was accustomed to discuss the deepest questions of philosophy and

government. In Williamsburg, Jefferson was one of the leaders in all social functions, and always attended the balls given in the Apollo Room of the Raleigh Tavern. Probably his first year at college was spent among too many festivities, but during his second year he is said to have been a most diligent student, often devoting 15 hours a day to his books. After two years of college work, he commenced the study of law under George Wythe, but did not apply for admission to practice before the general court of Virginia till 1767. Jefferson was now 24 years of age; he had a large farm of 1,000 acres (soon increased to 5,000 acres) to which he gave his personal supervision. Though he devoted much time to this farm, he succeeded so well as a lawyer that his profession soon paid him \$3,000 annually.

A Revolutionist.—In 1769 he was returned by Albemarle County a member of the House of Burgesses, an honor which his father had had before him. This was Jefferson's beginning as a statesman. He had stood in 1765 in the hallway of the House of Burgesses when Patrick Henry (q.v.) offered his famous Resolutions against the Stamp Act, and from Patrick Henry he imbibed the spirit of revolution. Just as soon as he became a member of the Burgesses, he joined the party of resistance to England. He was by nature a bold and fearless thinker, and when a mere boy he had had engraved on a seal as his motto, "Resistance to tyrants is obedience to God," a principle to which he held throughout his long and eventful life. Jefferson was present when the House of Burgesses passed the resolutions of 1769. He was one of those who signed the agreement not to import goods from England. He was also a member of the House of Burgesses when, in 1773, it established a Committee of Correspondence between Virginia and the other colonies. Some think that the resolutions for such a committee were drawn by Jefferson, though they were offered in the house by his kinsman, Dabney Carr (q.v.). Of this committee Jefferson was a member. He served again in the House of Burgesses in 1774, and was one of those who voted for the resolution appointing a day of fasting and prayer because of the oppressive measures which England had passed against the city of Boston. When the governor dissolved the assembly, Jefferson met with those discontented members who called for a general congress of the colonies and asked the freeholders of Virginia for a convention to consider the state of the colony. To this convention Jefferson was returned by the people of Albemarle. The convention of 1774 was the first extra-legal assembly to meet in Virginia. Jefferson was unable to be present, having been taken ill on his way to Williamsburg. However, his influence was felt through a document called *"The Summary View of the Rights of British America,"* which was intended to be a series of instructions to the Virginia delegates to the First Continental Congress. The instrument marked him as a revolutionist, and as an advocate of independence from England, for in it he distinctly claimed that the colonies had a right to govern themselves without interference from the English Parliament. His views were too radical for the Virginia convention to give them its official stamp.

Jefferson was also elected a member of the

THOMAS JEFFERSON,
THIRD PRESIDENT OF THE UNITED STATES.

JEFFERSON

convention of 1775, which met at St. John's Church, Richmond, and when Patrick Henry by his eloquence carried the colony into open rebellion against the mother country, Jefferson was appointed a member of the committee to devise a plan for organizing the militia of the colony. Shortly after this he became a member of the Second Continental Congress. When he entered that body, he was 32 years of age, being one of the youngest three members. Here he was placed on such important committees as those which drafted a paper to explain the rebellious attitude of Massachusetts at Lexington and Concord, and to reply to Lord North's "Clementary Policy." On each committee he showed such a strong republican tendency that his suggestions were not accepted. The members of the Continental Congress of 1775 were not far-sighted enough to see that independence was the only course. Finally, in the spring of 1776, there came to the Virginia members of Congress instructions from the Virginia convention of 1776 that the united colonies should be declared free and independent States; and accordingly Richard Henry Lee, called the American Cicero, moved that a Declaration of Independence should be adopted. In accordance with the motion, a committee was appointed and the members were elected by ballot. Jefferson's facility for writing was so well known to the Congress that he received the highest number of votes and was named as chairman of the committee over such men as John Adams, Benjamin Franklin, Roger Sherman and Robert R. Livingston. To him as chairman fell the task of drafting that immortal document which stands in the history of the world as the most revolutionary political paper ever written. On 4 July 1776, the instrument, practically as offered by Jefferson, was unanimously adopted and to it were placed the signatures of all the members of Congress then present, except one. The principles set forth in that document mean a government by and for the people, and show that Jefferson was far ahead of his day; for it is only at the dawn of the 20th century that we are beginning to comprehend the great and universal truths that Jefferson made known to the world (See DECLARATION OF INDEPENDENCE.) Jefferson retired from Congress in 1776, and, on returning to his native State, entered the Virginia legislature with the hope of revising and modifying her laws so that they might accord with republican government. For three years he served in the House of Delegates. During this time he succeeded in breaking down the laws of primogeniture and entail, in practically disestablishing the English Church, and in passing one of the best laws that the world has ever seen for public education providing an ideal system from the primary school to the university. Through his influence the legislature appointed a committee to revise thoroughly the laws of Virginia. The committee was composed of Edmund Pendleton, George Wythe and Jefferson. After two years, the revision, chiefly done by Jefferson, was submitted to the General Assembly, but it was not adopted *in toto*. Finally, however, in 1785, while Jefferson was in France, his faithful friend and political follower, James Madison, secured the passage of nearly all of Jefferson's work. It was at this time that the legislature approved the famous Statute for Re-

ligious Freedom, by which the complete separation of Church and State was accomplished, except the taking away of the *glebe* lands, a thing which was done in 1802. Jefferson wished even more radical changes in Virginia, such as the equalizing of representation on population instead of having two representatives from each county. He also desired that the suffrage should not be restricted to land owners, but that it should be extended to all men who might be subject to military duty. He likewise advocated more local self-government in the counties and towns of the State. He even went so far as to advocate the emancipation and the deportation of the slaves from Virginia. These measures were too radical for the Virginia Assembly, and were rejected. It is interesting to note, however, that all of them have since been accomplished save the deportation of the negroes.

Governor of Virginia.—Jefferson was governor of Virginia from June 1779 to June 1781. These were trying times; Virginia was invaded by British troops under Cornwallis, and Jefferson lacked money and resources with which to defend properly the State. His administration has often been criticised, some claiming that he was a mere doctrinaire and not a practical man; but close scrutiny shows that he did all that then lay in his power.

In Congress and at the French Court.—In 1783 Jefferson entered the Congress of the United States. To this body he proposed in 1784 a plan for the government of the Northwest Territory which Virginia so generously gave to the Union. One clause of this plan provided for the prohibition of slavery in that territory after 1800, and for this reason the plan was not adopted. In 1787, however, Congress enacted a bill for the government of the Northwest much like the original draft of Jefferson. From him Congress had the plan of our present decimal monetary system. In 1784 Jefferson was sent to France to join Benjamin Franklin and John Adams in negotiating commercial matters with foreign countries, and in 1785 he succeeded Franklin as our minister plenipotentiary to the French court. Through his efforts many unjust impositions on American commerce were removed by the French government.

Secretary of State.—In October 1789 he returned to America, and the following year became secretary of state in Washington's cabinet, in which position he opposed Hamilton (q.v.), who favored the exercise of extensive powers by Congress. Jefferson believed in a real federal relation between the States, and in a restricting of the congressional powers to purely constitutional authorizations. The final line of cleavage came when Congress passed a bill to establish a national bank. Hamilton submitted to Washington a paper asserting that such a step was legal, while Jefferson made a vigorous written protest showing that the bill was unconstitutional. Washington approved the measure, thus accepting Hamilton's views as correct. The Bank Bill, along with similar congressional acts, caused the establishment of two distinct parties—the Federalist or Loose Construction Party, headed by Hamilton, and the Anti-Federalist or Strict Construction Party, with Jefferson as its leader. Jefferson's followers were usually called the Democratic-

JEFFERSON

Republicans. (See BANKS AND BANKING, AMERICAN.)

In December 1793 Jefferson resigned from the cabinet and returned to Monticello, where he remained for four years, studying farming. His estate at this time contained 10,647 acres of land, worked by 154 slaves, and stocked with 34 horses, 5 mules, and 249 cattle. Among the negroes he had a sort of industrial (manual-training) school, and taught them to be cabinet-makers, bricklayers, masons and smiths.

Vice President.—From his retirement at Monticello, Jefferson was called to become Vice President in 1797, a position which he held till 1801. During these four years, he bitterly opposed the so-called monarchical tendencies of the Federal party as seen in the Alien and Sedition Acts (q.v.), and he boldly asserted the compact theory of State sovereignty in the Kentucky Resolutions of 1799. The Kentucky Resolutions and Virginia Resolutions of 1798-9 (the latter framed by Madison after a copy of the Kentucky Resolutions sent him by Jefferson), made the platform, so to speak, of the Democratic-Republican party which elected Jefferson as President in 1801.

President.—From 4 March 1801 to 4 March 1809 Jefferson was President. He was the first President to be inaugurated in Washington City. He believed in rotation in office, and in pursuance of this idea, removed a number of Federalists from their positions. His great act, however, was the purchase of the Louisiana Territory from France for the sum of \$15,000,000. This vast territory was acquired for two reasons: (1) In order that the United States might have control of the Mississippi River, and the port of New Orleans; and (2) that the United States might not be hampered by European countries in the development of a republican form of government. As secretary of state in Washington's cabinet, Jefferson had practically asserted what was afterward known as the Monroe Doctrine, when he claimed that the United States should see that no European countries, other than those already holding possessions, secure a foothold in America. In 1801 Jefferson viewed with alarm the transfer of the Louisiana Territory from Spain to France, for he feared that, with France added to Spain, England and Russia, in control of colonies in America, republican government would have a hard struggle. Jefferson was accused of inconsistency for having sanctioned the Louisiana Purchase (q.v.), for if he had applied the strict construction principle of the Constitution here as in such acts of Congress as the establishment of the national bank, this Territory could not have been purchased, there being no provision in the Constitution allowing territorial expansion. But Jefferson's political sagacity kept him from refusing this great opportunity, and his wish of expansion caused him to advocate earnestly the purchase of Florida from Spain. It was 13 years later before his desire was accomplished. The second administration of Jefferson was not so successful as the first. It opened with a war against the Tripolitan pirates who were plundering American commerce. The outcome of this war was to increase our influence among the nations of the world. The last years of the second term were marked with difficult complications arising out of the Napoleonic wars. Napoleon tried

to prevent the United States from trading with England, and England retaliated by attempting to cut off all commercial relations between the United States and France. Many American vessels were seized by both England and France. Adding to this indignity, England claimed the right to search American vessels for English seamen, and an English war vessel actually fired on an American man-of-war, killing three of the crew and wounding 18. Jefferson tried to meet the restrictions on American commerce by the Non-Importation Bill and the Embargo Act. To enforce the measures all of the New England ships would have been shut up in American harbors. The New England merchants preferred to run the risk of losing their ships to keeping them without traffic; therefore they began to abuse the President and his policy. The result was that Congress felt forced to repeal the Embargo Act. Jefferson always claimed that had the embargo been enforced the United States would have gained its rights without the second war with England in 1812. (See EMBARGO IN THE UNITED STATES.)

Private Citizen.—On 4 March 1809, Jefferson retired from the White House, and spent the remaining 17 years of his life at Monticello. In these latter days he was known as the "Sage of Monticello," and to his home came people of prominence from all parts of the world to consult with him on great questions of politics and economics. Often his housekeeper had to provide beds for 50 guests. The demands which were made on his hospitality were so great that he died a bankrupt. During this period of his life he did all that he could to encourage better methods in agriculture, to reform the government of Virginia, and to develop in it a better system of education. The crowning event of his life was the establishment of the University of Virginia (q.v.) in 1819. He died on 4 July 1826, just 50 years from the day that has made him famous in all history, and by a singular coincidence his old rival and political antagonist, John Adams, passed away on the same day. Jefferson asked that three things be inscribed on his tomb: "Author of the Declaration of Independence; of the Statute for Religious Liberty in Virginia, and Founder of the University of Virginia,"—three acts which have made him famous.

Jefferson's Principles.—Jefferson stands in history for: (1) Republican government and the sovereignty of the people; (2) Opposition to privileged orders of nobility and the entail system; (3) Universal education and local circulating libraries; (4) Separation of Church and State; (5) Freedom of thought and speech; (6) Local self-government; (7) Economy in government and small public debt; (8) A policy of peace; (9) Political equality and universal suffrage; (10) Strict construction of the Constitution and the sovereignty of the States; (11) Well-trained militia and small standing army; (12) Metallic money, either gold or silver, as a standard, and no paper legal tender; (13) Opposition to bounties and monopolies; (14) Emancipation and deportation of slaves; (15) Expansion of the United States to include Louisiana, Florida, Cuba, and Canada; (16) Maintenance of Indian reservations; (17) Judiciary beyond the control of the legislative or executive branches of government; (18) Small navy; (19) Opposition to nepotism; (20) Rotation in

JEFFERSON-BURR IMBROGLIO — JEFFERSON CITY

office; (21) Opposition to all secession movements, North or South. This review will show that Jefferson probably gave to the world more broad principles of government than any other man. Wherever republican forms of government exist there the name of Jefferson will always be uttered with reverence and respect.

Of Richmond College, Richmond.

Jefferson-Burr Imbroglio, im-brō'lēō, a disputed Presidential election which resulted from a defective clause in the Constitution and caused its amendment in 1800. By its original provisions, the person who received the highest number of electoral votes should be President, the next highest Vice-President. Each set of electors had informally agreed that to save the pride of the leading candidates (Jefferson and Burr, Adams and Pinckney) each pair should have equal votes, and with one exception never reflected that this meant a tie; one Rhode Island Federalist elector cast his second vote for John Jay instead of Pinckney, and there is an unproven charge that Burr intrigued for an extra vote over Jefferson. They, however, received 73 each, and the Federalist House had to choose between the two Democratic candidates. Rules were adopted for the balloting, among the chief being that the Senate should be admitted, that the balloting should be in secret session, and that the House should not adjourn till a choice was made. The Federalists in caucus decided to vote for Burr; perhaps partly to spite the Democrats—Jefferson being their great national leader and the great Federalist terror, and the man the Democrats had intended to vote for as President—and partly because Burr as a New York man would consult Northern commercial interests, which the Virginian Jefferson might antagonize. They were right in this; Burr would not have laid the Embargo. Their solid vote would have elected Burr by one (nine out of 16 States); but they could not hold their members, three of whom bolted and voted for Jefferson to satisfy public feeling in their districts. Thus Jefferson had eight States, Burr six, and Vermont and Maryland were divided. But the Burr electors in the last two secretly agreed with Bayard of Delaware, who had also voted for Burr, that if there were likely to be bad blood and danger from prolonged balloting, they would stop it by voting for Jefferson. The casting vote thus lay with Bayard, who justly commanded confidence; but as the agreement was not known, the situation seemed much more perilous than it was. The balloting lasted a week without change. Some of the Federalists plotted to have it last till John Adams' term expired, and then let the others fight it out, or leave it by special act to Chief Justice John Marshall (Federalist), as a sort of regent trustee. The Democrats countered by resolving either to have Jefferson and Burr jointly (one of them certainly being President) call a special session, or to seize the capital by a militia force, call a convention, and revise the Con-

stitution. Finally, after 34 ballots, the confederate electors decided that if Jefferson would give a guarantee for the civil service, he should have the election after one more ballot; he gave the guarantee, and was elected on the 36th ballot by 10 to 6 (States). Burr became Vice-President; that the attempt to put him at the head was mainly due to real fear for commerce is made probable by the fact that every New England State except the one (Vermont) which had no commerce, voted for him to the last. This affair resulted in the passage of the Twelfth Amendment (see CONSTITUTION OF THE UNITED STATES), which obliged the electors to specify their choice for the offices on distinct ballots, and enlarged the range of choice to three candidates in case of tie.

Jefferson, Texas, city, county-seat of Marion County; on the Cypress Bayou, and on the Missouri, K. & T. and the Texas & P. R.R.'s; about 20 miles from the eastern boundary of the State and 142 miles east of Dallas. It was settled in 1850 and incorporated in 1866. It is situated in an agricultural and stock-raising region with rich iron ore deposits in the vicinity. Some of the principal industrial establishments are furnaces, machine-shops, foundries, saw-mills, cottonseed-oil mills, and large storage houses. The shipments are chiefly articles manufactured in the city, vegetables, grain, cotton, live stock, and fruit. The principal buildings are a government building, the city and county buildings. An iron bridge across the Bayou and good roads assist in making Jefferson the trade centre for a large part of Marion and Cass counties. Pop. (1900) 2,850.

Jefferson, Wis., city and county-seat of Jefferson County, at the junction of the Rock and Crawfish rivers, 50 miles west of Milwaukee; and on the Chicago & Northwestern railroad. It was settled in 1837 and is governed by a mayor and a council elected every two years under a charter of 1893. It has pork-packing plants, flour-mills, tanneries, brick and tile works, carriage and wagon factories and other industries. The city owns and operates the waterworks and the electric-lighting plant. Pop. (1900) 2,584.

Jefferson City, Mo., city, capital of the State, and county-seat of Cole County; on the Missouri River, and the Chicago & A., and the Missouri P. R.R.'s; 125 miles west of Saint Louis. It is the farming and manufacturing trade centre for Cole and adjacent counties; has manufactories of flour, shoes, clothing, beer, brooms, bricks, farming implements, carriages and wagons, and iron foundries. It is the seat of Jefferson City College, the general western offices of the Standard Life Insurance Company, Lincoln Institute, State Capitol building, State penitentiary, State armory, governor's mansion, Supreme Court building, United States courthouse, and the Carnegie Public Library. It has gas and electric light plants, 2 national banks, daily, weekly, and monthly periodicals, and an assessed property valuation exceeding \$800,000. Jefferson City was settled in 1826 and was first incorporated in 1839. A mayor and council elected every two years administer the affairs of the city. Pop. (1890) 6,742; (1900) 9,664.

JEFFERSON RIVER—JEFFRIES

Jefferson River, Montana, a stream about 200 miles long, formed by the union of the Beaver Head and Wisdom (or Big Hole) rivers in Madison County. It unites with the Madison and Gallatin to form the Missouri.

Jeffersonton, Engagement at. Early in October 1863 the Army of the Potomac, under command of Gen. Meade, lay around Culpeper Court House, with the advance of two corps on the Rapidan. Gen. Lee, who was south of the Rapidan, determined to flank Meade's position, seize the Orange and Alexandria Railroad north of the Rappahannock, and intercept his retreat upon Washington. Informed of the movement, Meade withdrew his army to the north side of the Rappahannock, 11 October, his rear-guard of cavalry having a sharp engagement with the Confederate cavalry at Brandy Station. Believing that the Confederate army was moving upon Culpeper, Meade turned about and on the 12th, threw three infantry corps and a cavalry division south of the Rappahannock, with instructions to push forward and find and strike Lee, if at Culpeper. When they reached Brandy Station the Confederate army was nowhere in that neighborhood. At this time Gen. Gregg's division of Union cavalry was guarding the upper fords of the Rappahannock and Hazel rivers; on the morning of the 12th Col. Gregg's brigade crossed the Rappahannock near Sulphur Springs; his pickets at Jeffersonton being driven in, he marched for that place, found it in possession of the enemy, drove them from the town, and occupied it. That morning Fitzhugh Lee's cavalry division, leading the Confederate advance from near Madison Court House, crossed Hazel River at Starks' Ford and pressed on toward the Rappahannock. The 11th Virginia cavalry drove Gregg's skirmishers into Jeffersonton and attacked the two regiments in the town, but was driven out after losing several men. The 7th and 12th Virginia were now sent to the left and right, encircling the town, a combined attack was made, and Gregg was utterly routed and driven across the Rappahannock, with a loss of about 400 men, most of them captured. The Confederate loss was about 40 killed and wounded. When Meade heard of the engagement, and that Lee was crossing the Rappahannock at Warrenton Springs, he hastily recrossed the river, withdrew to Auburn and Catlett's Station and, on the 14th, to Centreville, Lee following closely and attacking his rear at Auburn and Bristoe Station during the day. Consult: 'Official Records,' Vol. XXIX.; Walker, 'History of the Second Army Corps.'

E. A. CARMAN.

Jeffersonville, Ind., city and county-seat of Clark County; on the Ohio River, and the Baltimore & O. S. W., the Pittsburg, C. C. & St. L. and several other railroads; 50 miles southwest of Evansville. It is opposite Louisville, Ky., with which it is connected by railroad bridges. It contains the Southern State penitentiary, high school, public library, prison library, United States quartermaster's supply depot, and has waterworks, gas and electric lights, street railways, large car works, 2 national banks, daily, weekly, and monthly periodicals, and an assessed property valuation of about \$1,700,000. Being at the head of the Ohio falls excellent water power is obtained here and the city has

numerous industries, among them extensive works for freight and passenger cars and for building river steamboats. The mayor and council are elected biennially; the police commissioners are appointed by the governor of the State. Pop. (1890) 10,666; (1900) 10,774.

Jeffrey, jēf'rī, **Francis**, Lord, Scottish judge and critic: b. Edinburgh 23 Oct. 1773; d. Craigbrook Castle, near Edinburgh, 26 Jan. 1850. He was educated at the University of Glasgow, and Queen's College, Oxford, and was admitted to the Scottish bar in 1794. He assisted in establishing the 'Edinburgh Review' in 1802 with Sydney Smith, Lord Brougham, and others, and after two numbers had been issued became its editor, a position which he held till June 1829. In 1831 he was made lord-advocate, and sat for several years as member of Parliament for Edinburgh. He was made a lord of session in 1834, and continued during a period of 16 years to be one of the ablest and most popular judges of the supreme court in Scotland. Consult: Cockburn, 'The Life of Lord Jeffrey' (1852); Gates, 'Three Studies in Literature' (1899).

Jeffreys, jēf'rīz, **George**, Lord, English judge: b. Acton, near Wrexham, Wales, 1648; d. London 19 April 1689. He was called to the bar in 1668, and soon after was chosen recorder of London. He was appointed, successively, a Welsh judge and chief justice of Chester, created a baronet in 1680, and became chief justice of King's Bench in 1683. He was one of the advisers and promoters of the arbitrary measures of James II.; and for his sanguinary and inhuman proceedings against the adherents of Monmouth on the famous 'Bloody Assize,' was rewarded with the post of lord high chancellor (1685). After the abdication of King James the chancellor, who had disguised himself as a seaman, was detected by a mob and carried before the lord mayor, who sent him to the lords in council, by whom he was committed to the Tower, where he died. Consult: Woolrych, 'Memoirs of the Life of Judge Jeffreys' (1827); Campbell, 'Lives of the Lord Chancellors,' Vol. IV. (1849-57); Macaulay, 'History of England,' Vols. I. and II. (1856); Irving, 'Life of Judge Jeffreys' (1808).

Jeffries, jēf'rīz, **John**, American physician: b. Boston, Mass., 5 Feb. 1744; d. there 16 Sept. 1819. He was graduated at Harvard in 1763, studied medicine at London and Aberdeen, and returning to Boston in 1769 he entered upon a lucrative practice, which continued until the evacuation of the town by the British troops, whom he accompanied to Halifax. After serving as surgeon-general of the troops in Halifax, he was appointed in 1779 surgeon-major of the forces in America. In the succeeding year he established himself in London in the practice of his profession, but also occupied himself much with scientific studies, and in the prosecution of his experiments in atmospheric temperature undertook 7 Jan. 1785, a remarkable voyage in a balloon from Dover cliffs across the British channel, landing in the forest of Guenness in France. This was the first successful attempt at aerostation on an extended scale, and Jeffries in consequence received many attentions from the learned societies of Paris. In 1789 he returned

JEHOVAH — JEKYLL

to Boston, where he practised his profession until the close of his life. He announced a course of lectures on anatomy in Boston in 1789, but so great was the prejudice against the practice of dissecting, that on the evening of the second lecture a mob broke into his anatomical room. The course thus interrupted was never resumed, and the single lecture delivered by Jeffries is said to have been the first public one on anatomy given in New England.

Jehovah, je-hō'vā, the most sacred name applied to God among the Jews, though the Hebrew word in the English Bible is generally translated by *LORD* (in small capitals). The case is similar with the Greek version (the Septuagint), which renders this word by *Kyrios*, and with the Latin Vulgate, which translates it by *Dominus*, both these words signifying Lord. The proper form of the name is now generally believed to be *Yahvch* or *Yahweh*. Why there should be any doubt about the matter is explained by the fact that in Hebrew only the consonants were written, giving the form *Yvh*, and the name itself was never uttered, the Jews in reading substituting another divine name, usually *Adonai*. The exact meaning of the word is doubtful, but as a form of the Hebrew verb "to be" some explain it as, He who is, was, and will be, or the Eternal and Unchangeable, and it seems certainly to imply existence. The awe which the Hebrews cherished for this name led them to avoid pronouncing it, as they still do. The monotheistic conception of the Jehovah of the Israelites differs from all other theological conceptions of that age. No image of him was allowed. He was the invisible protector and king of Israel, worshipped by obedience to his commandments, and an observance of the ceremonies established by the law. As is well known, in some parts of the Pentateuch *Elohim* is used almost exclusively, in others *Jehovah*, and this has led many to imply a corresponding difference of authorship. Others deny that this is at all a necessary deduction, maintaining that either name might be used by the same writer according to the conception of the Most High that was in his mind at the moment, *Elohim* being the abstract expression for absolute Deity, apart from the special notions of eternity, unity, holiness, etc.

Jehovist, je-hō'vist, sometimes called **JAHWIST**, a hypothetic author of the Pentateuch, who used the word Jehovah, or Jahweh, as the name of God instead of Elohim, which term denotes the Supreme Being in other passages of the sacred canon. To the writer who employs the latter designation is applied the term Elohist. According to the theories of many modern Biblical critics the present Pentateuch is a compilation from two original records, one made by an Elohist, the other by a Jehovah. The Jehovah history is supposed to be the older of the two (by some critics it is dated 950 B.C.), and to have consisted of an account of Jehovah's dealings with the chosen people up to the conquest of Palestine west of the Jordan. It is a religious history of the attainment of the Promised Land. In this history was emphasized the supremacy of Jehovah as the one God, creator of the world, and the national God and Father of the chosen people, in whose affairs He interposes as He appeared to their early fore-

fathers in the shape of a man or an angel. In the Elohist record, which is supposed to cover the same period and to have been written 700 B.C., there is a more modern interpretation of history attempted. The anthropomorphic suggestions of deity are softened, Elohim interposes merely by a voice, speaking to his people in words of encouragement or rebuke. Through the narrative of the hypothetical Elohist there runs also a tone of sadness, there are anticipations of coming disaster and disappointment.

The Jehovahistic or Jahwistic editor who combined these two histories is supposed to have lived in the 7th century B.C., while in the 4th century B.C. a third post-exilic writer added to these combined elements the legal codes which swelled the Pentateuch into the Hexateuch.

Jehu, jē'hū, general of the army of Joram, king of Israel. The prophet Elisha sent one of the school of the prophets to anoint him king over Israel, and in a sudden revolution Joram was slain and Jehu reigned in his stead. He was the first of a new, the fifth, dynasty, and reigned 843-815 B.C. On his accession he massacred all the family of Ahab, including his wretched wife Jezebel, and put the priests of Baal to the sword. In order to obtain possession of the kingdom of Judah he slew Ahaziah the king, and 42 of his family. But his reign was not a prosperous or successful one, and by an invasion of the Assyrians he lost all the territory east of the Jordan. His name has been found on the black obelisk discovered by Layard at Nineveh, and now in the British Museum. This obelisk was set up by Shalmaneser II., and the inscription refers to the tribute paid by Jehu to the Assyrian monarch.

Jejeebhoy, Sir Jamsetjee, Parsee merchant and philanthropist: b. Bombay 15 July 1783; d. there 15 April 1859. By his energy and business talents he succeeded in achieving for himself the position of the first native merchant in India, and realizing a fortune of nearly a million sterling. The munificence displayed by him toward all benevolent and public objects, without regard to class or creed, was of the most princely kind, his donations from first to last being estimated at about \$1,500,000. Among benevolent institutions founded by him are the great hospital at Bombay which bears his name, the establishment in the same city for the education of poor Parsee children, and the *dhurumsallas*, or places of refuge for travelers in various parts of the country. He also constructed the causeway uniting the islands of Bombay and Salsette, the waterworks at Poonah, the bridges at Earla, Parta, and Bartha, and other public works. He was knighted in 1842, and in 1857 made a baronet. A statue was subsequently erected in honor of him in the town-hall of Bombay.

Jejunum, je-joo'nūm (Latin, *jejunus*, empty), the second portion of the small intestine, succeeding the duodenum, and so named from its generally being found empty after death. The duodenum extends to about 12 inches in length, and the jejunum forms two fifths of the remaining portion of the small intestine. See **INTESTINE**.

Jekyll, jē'kil, Gertrude, English horticulturist: b. London 29 Nov. 1843. She holds the

JELLY—JELLYFISH

gold medal of the Royal Horticultural Society and has published: 'Wood and Garden' (1899); 'Home and Garden' (1900); 'Wall and Water Gardens' (1901); 'Lilies for English Gardens' (1901); 'Roses for English Gardens' (1902).

Jelly includes every translucent juice so far thickened as to coagulate when cold into a trembling mass; as the juices of acid or mucilaginous fruit, currants, etc., which, by the addition of one part of sugar to two parts of juice, and, by boiling, have obtained a proper consistency. Jelly may be of either animal or vegetable origin.

1. *Animal Jelly*.—The soft parts, such as the muscles, skin, cartilage or integuments of animals, when boiled in water, yield a solution which on cooling solidifies to a tremulous jelly. The substance may also be prepared from bones by subjecting them, after crushing, to the united action of high pressure steam and water. Seventy pounds of bones, when treated with 1 pound of water in the form of steam, at a pressure of 4 pounds to the square inch, and simultaneously digested in 5 gallons of water, will yield about 20 gallons of a strong jelly. Animal jelly is a colorless, elastic, transparent substance, without taste or smell, which is almost insoluble in cold but very soluble in hot water. After boiling for some time in water a solution of animal jelly loses the power of gelatinizing upon cooling; alcohol, however, still throws down a precipitate having the composition of the original substance. When moist animal jelly is exposed to the air it putrefies, at first becoming acid, but afterward evolving ammonia.

Animal jelly seems to be nearly identical in composition with the tissues which yield it, so that we are unable to trace any chemical change, except, perhaps, the assimilation of water during the process of its manufacture. There is probably a rearrangement of the atoms accompanying this assimilation of water, but the subject has not yet been sufficiently studied. The following analysis shows the average percentage of carbon, hydrogen, and nitrogen in animal jelly:

	Carbon	Hydrogen	Nitrogen
(1)	49.0	7.0	18.0
(2)	50.0	6.5	17.5

Various observers have also detected sulphur among its constituents.

2. *Vegetable Jelly*.—When the juice of fruits is heated with sugar, the liquid forms a stiff jelly on cooling. It appears from the researches of Frémy and others that unripe fruits contain a compound of carbon, hydrogen, and oxygen, called *pectose*; as the fruit ripens, this substance is transformed into *pectin*, the change being brought about chiefly by the influence of a peculiar ferment called *pectase*, which is contained in the fruits. As pectin is soluble in water, the expressed juice of ripe fruits contains a large quantity of this substance, which on heating to a temperature of about 105° F. is converted into one or more substances which have not as yet been completely studied, but which have the property of gelatinizing on cooling. The principal of these substances are *pectic* and *metaplectic* acids. This latter acid, when boiled along with another strong acid, whether mineral or organic, is decomposed, one of the products being pectin sugar, a substance which is

closely allied to glucose, so that in all probability there is produced in the very process of manufacturing jellies more or less of this sugar, which certainly is not cane-sugar, and which might, therefore, be by some regarded as an adulteration. The processes which, in the living plant, result in the transformation of pectose into pectin may be imitated on a small scale by heating the juice of unripe fruit with the pulp, which contains the ferment pectase, or with a dilute acid which induces the same change as this substance. Alkalies also produce a similar effect. The exact composition of these various pectous substances yet remains a matter of doubt.

Jellyfish, the medusa-stage of *Hydrozoa* (q.v.), but more especially the common name of *Scyphozoa* (formerly *Discomedusa*), the second class of the phylum *Calenterata* (q.v.). A familiar example is the common large jellyfish of the coast of New England, *Aurelia flavidula*. It sometimes reaches the diameter of 10 inches; its umbrella-shaped body is convex and smooth above, and from the under sides hang down four thick oral lobes which unite to form a square mouth-opening also giving off four tentacles. The margin of the umbrella or disk is fringed and bears eight eyes which are covered by a lobe. Just under the surface are seen the water-vascular canals, branching out from four primary canals radiating from the stomach. When in motion, the disk contracts and expands rhythmically, on the average from 12 to 15 times a minute.

The *Aurelia* spawns late in the summer, the females having yellowish ovaries, while the sperm glands of the males are roseate in hue. The eggs are fertilized in the sea, and the ciliated pear-shaped larva by October sinks to the bottom, attaching itself to rocks or shells, finally assuming a hydra-like shape, with often as many as 24 long slender tentacles. This is the *Scyphistoma* stage in which it remains about 18 months. From this it passes into the *Strobila* stage in which the body divides into a series of cup-shaped disks, each of which is scalloped on the upturned edge. These disks separate one after the other in March, and swim away as miniature jellyfishes called *Ephyra*. The *Ephyra* is at first about a fifth of an inch in diameter, and becomes a fully formed *Aurelia* in April, reaching maturity in August. Another but less common jellyfish on the coast of New England and in the North Atlantic is the great *Cyanea arctica*, or "blue jelly," which is nearly two feet in diameter, sometimes from three to five, and with very long string-like tentacles, sometimes extending from 20 to 100 feet, which are filled with stinging or lasso-cells (*trichocysts*), so that the animal is poisonous to fishermen and bathers. While these forms undergo a metamorphosis, in fact, an alternation of generation; other kinds, as *Pelagia*, etc., are known to develop directly from the egg, and even the *aurelia* under exceptional circumstances does not pass through the scyphistoma stage. The jellyfishes are divided into a number of groups. They are most numerous in the tropical seas, comprising forms of great beauty. Consult: Romanes, 'Jellyfish, Starfish and Sea Urchins' (1885); Packard, 'Zoology' (1897); Arnold, 'The Sea Beach at Ebb-tide' (1902).

JELLYFISHES.

JENA—JENKINS FERRY

Jena, yā'nā, Germany, town 12 miles east of Weimar, on the left bank of the Saale. It consists of the town proper and of four suburbs, and is a dull antiquated place. It contains a famous university which was opened in 1558, and attained its highest prosperity toward the end of the 18th century, when it numbered Schiller, Humboldt, Fichte, Schelling, and Griesbach among its teachers, and was attended by above 1,000 students. In 1844 the number had dwindled down to 411; but in 1902 it had about 800. It has 98 professors and instructors, who teach the different branches of law, medicine, philosophy, and theology; and possesses an anatomical theatre, botanical garden, observatory, good physical and chemical cabinets, and a library of 200,000 volumes. Pop. 15,499.

Jenckes, jēnks, Joseph, American inventor: b. Hammersmith, London, England; d. Lynn, Mass., 16 March 1683. About 1645 he came to the Massachusetts Bay colony, and in that year settled at Lynn, where he established the first iron-foundry in the colonies. He was also an inventor, and in 1646 obtained on an improved water-wheel the first recorded patent in America. He secured a patent also for an improved grass-scythe, and originated other improvements and inventions in machinery and tools. In 1654, under contract with the Boston selectmen, he built the first fire-engine in this country. In 1652 at the Lynn iron-works he cut the dies for the Massachusetts coinage, the first executed in America. Among these coins were the so-called "pine-tree" shillings, deriving their name from that emblem on the obverse side.

Jenkin, jēng'kin, Henrietta Camilla Jackson, English novelist: b. Jamaica about 1807; d. Edinburgh 8 Feb. 1885. In 1832 she was married to Charles Jenkin, an English naval officer. Her novels were lively studies of character and popular in their day, among the best being: 'Cousin Stella' (1859), a portrayal of West-Indian life and manners; 'Who Breaks, Pays' (1861), in which the flirt is admirably pictured; 'Skirmishing' (1862); 'Two French Marriages,' issued in New York as 'A Psyche of To-day' (1868); 'Within an Ace' (1869).

Jenkins, jēng'kinz, Charles Jones, American jurist and statesman: b. Beaufort County, S. C., 6 Jan. 1805; d. Summerville, Ga., 14 June 1883. He was graduated from Union College, Schenectady, N. Y., in 1824, and after the study of law began practice in Augusta, Ga. He was a member of the Georgia legislature in 1830 and after a short service as attorney-general of the State was a member of the legislature 1836–50, and a leader of his party there. He was State senator 1856–60, and was a judge of the Georgia supreme court 1860–5. He became provisional governor of his State in 1865, holding office till 1868, and presided over the Constitutional Convention of 1877. Consult: Jones, 'Life of C. C. Jenkins' (1884).

Jenkins, John Edward, English political and social writer: b. Bangalore, India, 28 July 1838. He was educated at McGill University, Canada, and the University of Pennsylvania, and sat in Parliament for Dundee 1874–80. He became famous by the publication of his 'Ginx's Baby, his Birth and Misfortunes' (1870), a clever satire aimed at the clumsy

handling of the problem of English pauperism. Among later works of his which have circulated widely are: 'Lord Bantam' (1871); 'Little Hodge' (1872); 'Jobson's Enemies' (1879–82); 'A Paladin of Finance' (1882).

Jenkins, John Stilwell, American biographer: b. Albany, N. Y., 15 Feb. 1818; d. Weedsport, N. Y., 20 Sept. 1852. He was a lawyer by profession, and at one period edited the Cayuga 'Times.' Among his works are: 'Generals of the Last War with Great Britain' (1841); an abridgment of Hammond's 'Political History of New York' (1846); 'Alice Howard' (1846); 'Life of Silas Wright' (1847); 'History of the Mexican War' (1848); 'Heroines of History' (1853).

Jenkins, Thornton Alexander, American naval commander: b. Orange County, Va., 11 Dec. 1811; d. 9 Aug. 1893. Entering the United States navy as a midshipman in 1828, he served therein during the war with Mexico. Appointed to investigate European lighthouse systems he framed the law passed in 1852 under which the existing lighthouse board is managed. He saw active service during the Civil War and was chief of the bureau of navigation 1865–9. From 1869 to 1871 he was naval secretary of the lighthouse board and commanded the East India squadron 1871–3. In 1870 he was appointed rear admiral and retired from active service in 1873.

Jenkins Ferry, Battle of. During the winter of 1863–4 the Union forces of Generals Steele and Blunt held the line of the Arkansas River, with headquarters at Little Rock; the Confederates, under Gen. Sterling Price, held that of the Washita, with headquarters at Camden, which was strongly fortified. On 23 March 1864 Steele started from Little Rock southward with about 8,000 men to co-operate with Gen. Banks' expedition up Red River, the objective point of both being Shreveport, La. Gen. Thayer, with 5,000 men, left Fort Smith on the 21st to join Steele at Arkadelphia, and Col. Powell Clayton, with a small cavalry force, marched from Pine Bluff in the direction of Camden, which was Steele's first objective. Steele reached Arkadelphia on the 28th, was joined near Elkins' Ferry, on the Little Missouri, by Thayer, and, after several severe skirmishes, in which the Confederates were defeated, flanked Price out of Camden, 15 April, and occupied it. Here he was fully informed that Banks had been defeated on Red River and was retreating, and his own position became very precarious. Gen. E. Kirby Smith, who had been opposing Banks, marched rapidly with three divisions of infantry — 8,000 men and 14 guns — to join Price and crush Steele. Steele was too strongly entrenched at Camden to be attacked, but he was greatly harassed and nearly surrounded by the gathering Confederates, his forage-trains, with their guard, were cut off and captured, and, the loss of a large supply-train at Marks' Mills, 25 April, with nearly an entire brigade and a battery, determined him to fall back to the Arkansas River. He left Camden on the night of the 26th, crossed the Washita, and had hardly begun his movement northward when Smith and Price pressed him vigorously and kept up a running fight, which was particularly sharp on the 29th, when Steele reached Jenkins' Ferry, on the Saline River. The river was swollen,

JENKS—JENNER

and Steele had crossed only part of his army when his rear brigade, commanded by Gen. S. A. Rice, was fiercely attacked by Price, and yielded some ground. But the brigade rallied, and, supported by a part of Engelmann's that had not yet crossed the river, engaged in a sanguinary fight lasting the greater part of the day. Three times the Confederates charged and were repulsed, and the Union line advancing, the Confederates fell back and did not renew the fight. Steele now crossed the river without further molestation, and moved leisurely to Little Rock, which was reached 2 May, and Thayer's division was sent back to Fort Smith. Price was so badly defeated that he made no effort to follow Steele north of Saline River. The Union loss at Jenkins Ferry was 63 killed, 413 wounded, and 45 missing. The Confederates report a loss of 86 killed, 356 wounded, and 1 missing. The Union loss during the entire campaign (23 March–2 May) was 102 killed, 601 wounded, and 1,072 missing, a total of 1,775. Consult 'Official Records,' Vol. XXXIV.; 'The Century Company's "Battles and Leaders of the Civil War,"' Vol. IV.

E. A. CARMAN.

Jenks, Edward, English publicist: b. Clapham, Surrey, 20 Feb. 1861. He was educated at Dulwich College and Cambridge University, and was dean of the faculty of law in the University of Melbourne 1889–92, and Queen Victoria professor of law in University College, Liverpool, 1892–6. He is now reader in English law at Oxford, and widely known as a writer on English law, his published works comprising: 'Constitutional Experiments of the Commonwealth' (1891); 'The Doctrine of Consideration in English Law' (1893); 'The Government of Victoria (Australia)' (1893); 'History of the Australasian Colonies' (2d ed. 1896); 'Outlines of English Local Government' (1895); 'Law and Politics in Middle Ages' (1897); 'A Short History of Politics' (2d ed. 1900); 'Edward I.' (1902); 'Parliamentary England 1660–1832' (1903).

Jenks, Jeremiah Whipple, American political economist: b. St. Clair, Mich., 2 Sept. 1856. He was graduated from the University of Michigan in 1878, and subsequently studied in Germany, at the University of Halle. He then studied law and was admitted to the Michigan bar. In 1886 he became professor of Greek, Latin, and German in Mount Morris College, Ill.; in 1886–9 was professor of political science and English literature at Knox College, Galesburg, Ill.; in 1889–91 professor of political economy and social science at Indiana University; and in 1891 became professor of political economy and politics at Cornell University. In 1899–1901 he was expert agent for the United States Industrial Commission on investigation of trusts and industrial combinations, and was also expert for the Department of Labor on the same subject. In 1902 he was commissioner of the United States War Department to the Philippines and other Oriental nations to investigate the condition of labor and other economic subjects. In 1903 he went to Mexico to consult with the minister of finance in regard to a change of the financial system. He has written: 'Henry C. Carey als Nationalökonom' (1885); 'The Trust Problem' (1900); 'Trusts and Industrial Combinations' (1900);

a part of the report of the Industrial Commission; and 'Report on Certain Economic Questions in the English and Dutch Colonies in the Orient' (1902); besides many magazine articles. He is recognized as one of the foremost authorities on the trust question, and his writings are marked by scholarly and accurate investigation, combined with unusual simplicity and clearness of statement.

Jenks, Tudor, American editor and author: b. Brooklyn, N. Y., 7 May 1857. He was graduated from Yale in 1878, from the Columbia Law School in 1880, studied art in Paris in 1880–1, practised law in New York in 1881–7, and in 1887 became a member of the staff of the 'St. Nicholas Magazine.' His writings include many magazine contributions in prose and verse, and 'The Century World's Fair Book' (1893); 'Imaginations, or Truthless Tales' (1894); 'The Boys' Book of Explorations' (1900), and 'Galopoff, the Talking Pony' (1901).

Jenner, jēn'ér, Edward, English physician, discoverer of vaccination as a preventive of the smallpox: b. Berkeley, Gloucestershire, 17 May 1749; d. there 26 Jan. 1823. Having adopted the medical profession, he visited London to attend the lectures of the celebrated anatomist John Hunter, in whose family he resided for two years. Returning to the country, he settled at Berkeley, to practise the various branches of his profession. His investigations concerning the cowpox were commenced about 1770, when his attention was excited by the circumstance of finding that some individuals to whom he attempted to communicate the smallpox by inoculation were not susceptible of the disease; and on inquiry he found that all such patients, though they had never had the smallpox, had undergone the casual cowpox, a disease common among the farmers and dairy-servants in Gloucestershire, who had some idea of its preventive effect. Other medical men were aware of the prevalence of this opinion, but treated it as a popular prejudice; and Jenner seems to have been the first who ascertained its correctness, and endeavored to derive from it some practical advantage. He discovered that the *variole vaccine*, or cowpox, as the complaint has been since termed, could be propagated from one human subject to another by inoculation, rendering all who passed through it secure from the smallpox. In 1798 he published a short treatise—'An Inquiry into the Cause and Effects of the Variolæ Vaccine'—and in July 1798, Cline, surgeon to St. Thomas's Hospital, introduced vaccination into that institution. The practice was adopted in the army and navy, and in the country generally, and soon spread to other countries, and honors and rewards were conferred on the author of the discovery. In 1802 a parliamentary grant was made to him of the sum of £10,000, and five years later a second grant of £20,000. Besides the treatise already mentioned, and 'Further Observations on the Variolæ Vaccine or Cow-Pox,' Jenner also published various letters and papers on the same subject, as well as on others. A famous paper of his on the cuckoo appeared in the 'Philosophical Transactions' in 1788. Consult: Baron, 'Life of Jenner'; Creighton, 'Jenner and Vaccination' (1889); Crookshanks, 'History and Pathology of Vaccination' (1890). The

JENNER — JEREMIAH

last-named work contains reprints of the 'Inquiry,' the 'Further Observations,' and other papers by Jenner. See VACCINATION.

Jenner, Katherine Lee Rawlings, English novelist: b. Hayle, Cornwall. She was married to Henry Jenner, and has published: 'A Western Wildflower' (1882); 'In London Town' (1884); 'Katharine Blythe' (1886); 'An Imperfect Gentleman' (1888); 'Love or Money' (1891); 'When Fortune Frowns' (1895); 'In the Alsatian Mountains.'

Jenner, Sir William, English physician: b. Chatham 1815; d. London 12 Dec. 1898. He was educated at University College, London, became in 1848 professor of pathological anatomy, and in 1857 of clinical medicine in that institution, and in 1861 physician to the queen. In 1862 he was appointed professor of the principles and practice of medicine in University College; in 1868 was created a baronet, and in 1872 a K.C.B., in recognition of his services during the severe illness of the Prince of Wales, now Edward VII. In 1881 he was elected president of the College of Physicians. He wrote various papers on specific diseases, and was the earliest to establish the difference in kind between typhus and typhoid fevers.

Jennings, jēn'īngz, Samuel, American colonial Quaker preacher: d. 1708. In 1680 he came from Buckinghamshire, England, to Burlington, N. J., and was governor of West Jersey in 1683. Becoming entangled in religious controversy he opposed the Quaker schismatic, George Keith, and in London in 1694, supported the action of the American Friends in regard to Keith. On returning to America he often made preaching tours through the various colonies, and after the recall of the English governor, Lord Cornbury, aided in restoring public order in the affairs of West Jersey.

Jennings, Sarah, DUCHESS OF MARLBOROUGH. See MARLBOROUGH, DUKE OF.

Jephson, jēf'sōn, Arthur Jermy Mountney, English writer of travels. He commanded a detachment under the explorer, Stanley, in the Emin Pasha relief expedition, was queen's messenger 1895-1901, and has been king's messenger from the latter date. He has published: 'Emin Pasha and the Rebellion at the Equator'; 'Stories Told in an African Forest'; 'The Story of a Billiard Ball' (1897).

Jephthah, jēf'tha, in Jewish history one of the judges of Israel (Judges xi., xii.). He was a son of Gilead, and was driven from home by his brothers, but when the Ammonites made war against Israel was summoned to defend his countrymen. Jephthah after trying conciliatory measures without success, put himself at the head of the Israelites, and defeated the enemy. He had made a vow that if he was victorious he would sacrifice to God as a burnt-offering whatever should first come to meet him from his house. He was met by his daughter, his only child, whom he accordingly sacrificed to the Lord (Judges xi. 29, 40). The way in which the vow was kept has given rise to much controversy, some authors maintaining that Jephthah put his daughter to death; others that he devoted her to perpetual virginity; others that he actually sacrificed her as a burnt-offering, and that, though prohibited by law of Moses,

human sacrifices occasionally took place among the Jews at this period.

Jep'son, Edgar, English novelist: b. London 28 Nov. 1864. He was educated at Oxford and has published: 'Sibyl Falcon' (1895); 'The Passion for Romance' (1896); 'The Keepers of the People' (1898); 'On the Edge of the Empire' (1900).

Jerboas, jēr'bō'az or jēr'bō'az, small rodents of the family *Dipodidae*, found in the sandy plains of Africa, Russia and southern Asia, and represented by a few species in North America. Their most prominent peculiarity is the great length of the hind legs, especially in the metatarsal portion, so that they look like miniature kangaroos. They walk ordinarily on their two hind feet, but when alarmed escape danger by long leaps. They are fawn-colored, as a rule, with long slender tails, large ears, big eyes, and nocturnal habits. They dwell in underground burrows and tunnels, many of which, more or less connected, are likely to be found together. Their food is mainly vegetable, but they also eat insects, eggs, etc.; they hibernate in cold climates, do not store food, and are the prey of foxes, jackals, wildcats, serpents, and Arab children. The most familiar species of jerboa is the Egyptian form (*Dipus aegypticus*), found in North Africa in arid places. The jumping-hare of South Africa (*Pedetes capensis*), and its ally, the jumping-mouse of North America (*Zapus hudsonius*), are also well-known examples of the family. The latter is a reddish "mouse," white underneath, which abounds all over the temperate parts of the country, and is easily recognized by its bounding gait. It is one of the longest and soundest of winter sleepers, preparing for its dormancy a warm ball-like nest of grass lodged in a bush or among strong weeds. Gerbils (q.v.) of Africa and India are often confused with jerboas, but are a group of true mice. Consult Lydekker, 'Royal Natural History,' Vol. III. (1895).

Jeremiah, jēr-e-mī'a, the second of the four major prophets of the Old Testament, the son of Hilkiah, of the priests that were in Anathoth, a town about three miles from Jerusalem. He flourished during the darkest period of the kingdom of Judah, under Josiah, Jehoiakim, Jecoeniah, and Zedekiah, having been called to the prophetic office in his youth, in the 13th year of the reign of Josiah 626 B.C. He continued in it till the 11th year of Zedekiah, when Jerusalem was taken by Nebuchadnezzar (588 B.C.). His task was to deliver messages and warnings to a corrupt people and to foretell the destruction of the nation. In Judah were two political parties—the one favoring an Egyptian alliance, the other a Chaldaean. Jeremiah repudiated both at first, but was driven over to the latter and unpopular party. He became the leader of this minority in contending with three features of popular infatuation—religious apostasy; neglect of justice; and false patriotism, which led the people frequently to break faith with Babylon, by bursting into revolt. He characterized Nebuchadnezzar as the servant of God, and prophesied the approaching burning of the temple. A cry for his life arose from the priests and prophets, and he escaped with difficulty. At last Jerusalem with its temple and palace was consumed with fire. Jeremiah was favorably

JEREMIAH — JEROBOAM

treated by the Babylonian conqueror, and offered a home at Babylon, but preferred to stay among the people left in Judah. One section of this party thought they saw in Egypt a safe place of refuge from the power of Nebuchadnezzar, and led the people together with Jeremiah to Tahpanhes, where, according to Christian tradition, the prophet was stoned to death by his countrymen, who were incensed by his rebukes. According to the Rabbinical tradition, however, he and Baruch made their escape on the conquest of Egypt by Nebuchadnezzar.

Jeremiah, Lamentations of, the title given by the Septuagint translators, by the Vulgate and English Bible, to a book of songs and dirges which is placed next to the book of the prophecy of Jeremiah. The book is divided into five chapters each of which contains a complete composition. In I., II. and IV. the death of the Jewish nation is bewailed with the utmost abandonment of grief. The form of each elegy is poetry of the most strictly artificial kind. The metre is that of the Kinah (q.v.), the metre employed in dirges from immemorial time in the east. As if to run down the whole gamut of sorrow each verse begins with a different letter of the Hebrew alphabet, arranged, generally, in the usual order.

The whole work may be thus briefly analyzed. Elegy 1: Lamentation over the city after the people have been swept off into captivity. Help is asked from Jehovah. Elegy 2: The destruction of the city mourned over. Jehovah again called upon as alone able to save. Elegy 3: Sufferings of "Jehovah's servant," a personification of the whole pious multitude, described. Elegy 4: Contrast between former gladness and the present misery, which is attributed to national transgression. Elegy 5: A final appeal for help in prayer to Jehovah.

The date and authorship of the Lamentations are matters of dispute. Few modern critics attribute them to Jeremiah. They show traces, however, of that prophet's language and sentiment, but internal evidence is not conclusive. Some think that they are referred to in 2 Chronicles xxxv. 25. Consult: 'Commentaries' of Payne Smith; Cheyne; Plumptre; and Löhr, 'Die Klagelieder Jeremias' (1894).

Jeremiah, The Prophecy of, a book of the Old Testament containing the utterances of that prophet. The writings of Jeremiah, or certain of them, were taken down by his pupil and friend Baruch. They must therefore have been originally spoken without being previously written out, although it is possible that the scribe or secretary took them down at his master's dictation. The roll of Baruch contained all that Jeremiah had spoken for 23 years; probably, therefore, many of the prophecies may have been sketched merely as outlines. The substance of these impassioned appeals is imbued with firm belief in God's unfailing covenant with Israel and with David. Although Jeremiah is not so often quoted by New Testament writers as is Isaiah, yet there is abundant evidence in their writings that they read him, and he is not only a prophet of denunciation and warning but also of Messianic hope and promise. He shows, moreover, an intimate acquaintance with Deuteronomy, the utterances of his prophetic predecessors, and the book of Psalms.

The book seems naturally to be divided into five parts, the first of which contains six discourses, each of the last three introduced by the formula of sanction, "The word which came to Jeremiah from the Lord." Each of these discourses includes sketches, outlines or skeletons of different prophecies each by a distinct formula of sanction. Take for instance, the first discourse (1 ch. to 20 ch.), the first sketch would be in the first chapter, verses 4 to 10, introduced by the formula, "The word of the Lord came unto me saying." There are at least four of these brief sketches in the first chapter.

The second part of the book consists of 15 prophecies, which are fuller and completer than those of the first part, each with its formula of sanction. They include poems, appeals, allegorical object-lessons, historic narratives, and one letter. The third part is a connected narrative in classic Hebrew, different in style from that of the first 20 chapters. The fourth part contains poetic invectives against Egypt, Philistia, Moab, Ammon, Edom, Damascus, Hazor, Elam and Babylon. The fifth part is a supplementary, adding details to the description of Jerusalem's downfall.

Jerfalcon, jér-fá"kn, or Gyrfalcon, a large and bold falcon of the Scandinavian mountains (*Falco gyrfalco*), represented by closely allied species or varieties in Iceland, Greenland and the Hudson Bay region, whose plumage is prevailingly white, with more or less blackish markings, especially about the face. It is one of the largest, strongest and most impetuous of its race; and has always been highly prized by falconers, among whom, by ancient laws, its use was restricted to men of ducal and princely rank. The bird is a rare winter wanderer to the United States from arctic Canada, where it breeds, and survives the winter mainly by killing ptarmigan.

Jericho, jér-i-kō, a once important city of ancient Palestine, near the foot of the mountains, on the west side of the Jordan plain, northeast of Jerusalem. Its name means "city of palms." The site is marked by mounds of sun-dried bricks, and called Tel es-Sultan; gardens and a fine spring are found there. The palms and balsams for which Jericho was formerly famed have disappeared. At the conquest of Palestine by Joshua, Jericho was the key to the country and was miraculously captured, destroyed by fire, and its rebuilding forbidden under a curse. It is now a poor village, much visited by tourists. It has two hotels, a Russian monastery and church.

Jerked Beef, beef cut into strips of about an inch thick, and dried in the sun. This method of preserving meat has been largely adopted in South America and Australia. Cut from the animals when in good condition these strips of flesh dry in the sun before decomposition commences, and will keep for any length of time. In the United States, jerked beef is common in the southwest, where the Indians prepared buffalo, deer and bear meat by cutting in strips and curing in the sun.

Jeroboam (jér-ō-bō'am) I., the first king of Israel, the northern kingdom. Having conspired against Solomon, he was obliged to escape to Egypt, where he remained until the monarch's death. He then returned to lead an insurrection

JEROBOAM — JERROLD

against Rehoboam, which ended in the formation of the kingdom of Israel, composed of the 10 revolted tribes. These tribes worshipped at Bethel and Dan, instead of going to Jerusalem. Jeroboam reigned from about 937 B.C. to 915 B.C.

Jeroboam II., king of Israel. He was the son of Joash. He reigned from about 782 B.C. to 741 B.C. His reign was evidently an active one. He was a skilful warrior, and regained territory which had been captured by the king of Aram in previous reigns. It was during Jeroboam's time that Hosea and Amos announced their prophecies.

Jerome, jér'om or jér'ōm, Saint (EUSEBIUS HIERONYMUS SOPHRONIUS), a father of the Latin Church: b. Stridon, between Styria and Hungary, about 331. His parents educated him with care in literary studies and he read the Greek and Roman classics at Rome under the famous grammarian Donatus. He did not escape uncontaminated by the licentiousness of the capital; but soon became inclined to the Christian faith. The catacombs and tombs of the martyrs first excited his devotion. His travels on the Rhine and in Gaul made him acquainted with several Christian preachers, and he was eventually baptized. After a long residence at Aquileia he went in 373 to Antioch in Syria, where he passed through a spiritual crisis and renounced pagan learning, and in 374 retired to the deserts of Chalcis. There he spent four years as a hermit in the severest mortifications and laborious studies. He left his solitude again to be ordained priest at Antioch, but soon after went to Constantinople to enjoy the instruction of Gregory Nazianzus. In Rome, where he became literary secretary to Pope Damasus, he made his appearance as a teacher. His exposition of the Holy Scriptures found favor with the Roman ladies. Marcella and Paula, rich patricians, are celebrated for the learned and ingenious theological epistles he wrote them, and for their rare monastic piety. Paula accompanied him to Palestine in 386, where he founded a convent at Bethlehem; here he remained till his death in 420. His writings show his active participation in the controversies of his day, and his letters give a very vivid idea of the condition of society at Rome. They are full of satiric strictness on the corrupt clergy, and are often as biting as Juvenal or Martial. Many of them are profoundly touching and full of fervent piety; others are lampoons traversed with vehement invective with the spirit of Plautinian ribaldry. His Biblical labors are highly valuable; his Latin version of the Old Testament from the original language is a marvellous achievement, and it may be said that ecclesiastical Latin, with all its peculiar graces, originated with Jerome's Vulgate. His principal claim to the gratitude of the Church lies in the fact that he was really the founder of Latin monasticism.

Jerome, Jerome Klapka, English humorist: b. Walsall 2 May 1861. He was at first a clerk in a railway office, afterward actor, schoolmaster, and journalist by turns. After many discouragements he succeeded in making a popular hit with his book, 'On the Stage—and Off' (1885), largely autobiographical; and his 'Idle Thoughts of an Idle Fellow' (1889) and 'Three Men in a Boat' (1889) made him famous in

America as well as at home. He edited the 'Idler' with Robert Barr (q.v.) (1892-7); 'To-Day' (1892-7); and has published several successful comedies: 'Sunset' (1888); 'New Lamps for Old' (1890); 'Miss Hobbs' (1900); etc.; and also 'John Ingerfield and Other Stories' (1894); 'Sketches in Lavender' (1897); 'Observations of Henry' (1901); 'Paul Kelver' (1902); etc.

Jerome, William Travers, American lawyer and politician: b. New York. He entered Amherst College, but did not complete his course there on account of failing health. He graduated from the Columbia Law School in 1884. In 1888 he was appointed assistant district attorney, in which position he saw much of the political corruption prevailing in the city. In 1890 he was active in the Municipal League, which opposed Tammany; in 1893 was assistant counsel of the Lexow Committee, in 1894 a member of the committee of 70, and manager of the campaign which resulted in the election of Mayor Strong. In the same year the mayor appointed him judge of the court of special sessions. In 1901 he was active in the Fusion campaign against Tammany; and in 1902 was elected district attorney of New York County; immediately after his election he established headquarters in the East Side of New York, in order to be within easy reach of the people who most needed his assistance; in this official position he has done very effective work in the breaking down of the system of protection of vice and maladministration of justice. In 1903 he again took an active part in the Fusion campaign.

Jerome of Prague, Bohemian religious reformer: b. Prague about 1370; d. there 30 May 1416. He was educated at the universities of Prague, Paris, Oxford, Cologne, and Heidelberg; and was in faith and sufferings the companion of the famous John Huss, whom he excelled in learning and eloquence, and to whom he was inferior only in moderation and prudence. His reputation for learning was so great that he was employed by Ladislaus II. of Poland to organize the University of Cracow; and Sigismund of Hungary caused Jerome to preach before him in Buda. He took a zealous part at Prague in the contest of his friend Huss against the authorities, and not unfrequently proceeded to violence, causing the monks who opposed him to be arrested, and even had one thrown into the Moldau. He publicly burned in 1411 the bull of the crusade against Ladislaus of Naples, and the papal indulgences. When Huss was imprisoned in Constance he could not remain inactive, and hastened to his defense. But attempting to return to Prague the Duke of Sulzbach caused him to be arrested in Hirschau and carried in chains to Constance. After an imprisonment of half a year he consented on 11 Sept. 1415 to recant the heresies with which he and Huss were charged. But this recantation did not deliver him, and after languishing a year, he solemnly retracted his recantation. On 30 May he was burned at the command of the council, and his ashes thrown into the Rhine.

Jerrold, jér'old, Douglas William, English dramatist and humorist: b. London 3 Jan. 1803; d. Kilburn Priory, near London, 8 June 1857. He was a midshipman in the navy 1813-15, and

JERROLD — JERSEY CITY

then quitting the service, was bound apprentice to a printer in London. By hard study he made himself master of Latin and Italian, besides acquiring an extensive knowledge of general literature, and at first attempted dramatic criticism. The bent of his genius, however, lay mainly in the direction of dramatic writing. Numberless pieces were produced by him before he was 20, but the first which won decided popularity was 'Black-eyed Susan,' represented for 300 successive nights at the Surrey Theatre in 1829. Among Jerrold's subsequent dramas were the 'Rent-day'; 'Nell Gwynne'; 'The Housekeeper'; 'Prisoner of War'; 'Bubbles of a Day' and 'Time Works Wonders,' the last named one of the most successful comedies on the English stage. He founded and conducted successively the 'Illuminated Magazine' and 'Douglas Jerrold's Shilling Magazine,' also acting as a most important member of the literary staff of 'Punch.' To this he contributed 'Mrs. Caudle's Curtain Lectures'; 'Punch's Letters to his Son'; the 'Story of a Feather.' He wrote several novels, among which are 'The Mad Mode of Money'; and 'Chronicles of Cloverhook' (1846). A selection of his essays edited by his grandson, Walter Jerrold, appeared in 1903. Though a powerful master of satire, he never allowed his wit, whether as an author or in private life, to be tinged with malevolence. Consult: W. B. Jerrold, 'Life and Remains of Douglas Jerrold' (1859).

Jerrold, Walter Copeland, English author and journalist: b. Liverpool 3 May 1865. Since 1890 he has been connected with the editorial staff of the London 'Observer,' and beside editing several reprints from the works of his grandfather, Douglas Jerrold (q.v.); Thackeray's prose works, etc., has published: 'Michael Faraday: Man of Science' (1891); 'Gladstone: England's Great Commoner' (1893); 'Oliver Wendell Holmes' (1893); 'The Triumphs of the Printing Press' (1896); etc.

Jerrold, William Blanchard, English journalist and miscellaneous writer, son of Douglas Jerrold (q.v.): b. London 23 Dec. 1826; d. there 10 March 1884. He edited Lloyd's newspaper for a long period and published: 'Cool as a Cucumber,' a novel (1851); 'Swedish Sketches' (1852); 'Life of Douglas Jerrold' (1858); 'At Home in Paris' (1866); 'Up and Down in the World' (1866); 'Paris for the English' (3d ed. 1868); 'The Cockaynes in Paris' (1871); 'The Best of all Good Company' (1871); 'Life of Napoleon III.' (1874-84).

Jersey Cattle. See DAIRY CATTLE.

Jersey (jér'zi) **City**, N. J., the most important suburb of New York since the annexation of Brooklyn, the second largest city in New Jersey, and seat of Hudson County. It occupies about five miles of the Hudson River frontage opposite lower New York: Paulus Hook, its starting point, is exactly opposite the Battery. It lies on a peninsula between the Hudson and New York Bay on one side, and the Hackensack and Newark Bay on the other; and is limited on the south by Bayonne, which takes up the lower end of the peninsula, and on the north by Hoboken. It has several ferry lines to different portions of New York, some of them operated by the great railroads which have their terminals here—all the roads from the

south and west: the Pennsylvania, Erie, Baltimore & Ohio, Lehigh Valley, Delaware, Lackawanna & Western, New York, Susquehanna & Western, Central of New Jersey, and the West Shore line of the New York Central. The Morris Canal ends here. Jersey City is also the terminal of several of the most important steamship lines between New York and Europe. Its area is 12,228 acres, or 19.1 square miles.

The city lies on a flat meadow about a mile wide from the river back to a sharp bluff; the business section occupies the former, the residence district the latter, with some very handsome streets of costly dwellings—though Grand Street in the business section is a notably beautiful residence street. The municipal improvements are of a high and thorough grade: paving (nearly all the streets are paved, largely with granite and asphalt), sewerage, water supply, etc. The trolley service extends to all the neighboring section of New Jersey. The parks are few and very small, less than in almost any other large American city; but along the ridge in the western part extends the magnificent Hudson County Boulevard, 19 miles long (the entire length of that county from Bayonne up, and five miles of Bergen County), 100 feet wide, and with a noble view of the river and upper New York, as well as the country west. The city hall with the soldiers' monument, the public library, and the Fourth Regiment armory, are among the conspicuous buildings. The intellectual facilities of the city are good, aside from its proximity to New York. It has 27 public schools, besides 10 Roman Catholic parochial schools, and for higher education a public high school, Hasbrouck Institute (1856), St. Peter's (Roman Catholic) College (1878), St. Aloysius Academy, and the German-American School. There is a public library with over 100,000 volumes; and a historical museum rich in colonial documents. The hospitals are the City, St. Francis, and Christ; there are several homes and asylums, and some convents.

The immense commercial and shipping interests of the city, though second only to those of New York, have no separate statistics, the customs report being included in that of the latter city. Its position on the great river, with Newark Bay in the rear and the entrance of Kill van Kull on the south, give it a most favorable commercial position, which has been improved by properly equipped wharves. The Pennsylvania and Erie roads have large grain elevators here. Among the leading industries are those of slaughtering and meat-packing: Jersey City is the meat depot of New York, and has two huge abattoirs, one on the river front and the other on the Hackensack meadows in the northwest. Its slaughter-house products in 1900 amounted to \$5,708,763. Its other manufactures are enormous, the total amounting to \$77,225,116 in 1900. They are exceedingly varied, no one having a great predominance except the tobacco manufacture, over \$6,000,000 a year; other important branches are iron and steel goods, locomotives, boilers, and heating apparatus; bridges, ships, and windmills; planing-mill products, cars, carriages, boxes, and cooperage; brass, copper, and zinc goods, electrical and scientific apparatus; pottery and glass; lead-pencils, and famous crucibles used in all chemical laboratories and smelting works; watches,

SOLOMON'S TEMPLE.
FROM DR. SCHIEK'S MODEL AT JERUSALEM.

JERSEY — JERUSALEM

jewelry, and musical instruments; sugar, and confectionery; mineral waters and patent medicines; soap and candles (a natural annex to the abattoirs), and perfumes; compressed gas; chemicals, paints, and roofing materials; paper, and window-shades; rubber goods; silk thread and goods; oakum; fireworks; printing and writing inks, and varnish; and hundreds of others. There are four national banks, and several State and private banks, with loan and trust companies.

The city has a two-year mayor and a council with only one chamber, called the board of aldermen; most of the other officials are appointed by the mayor, only the city clerk being appointed by the aldermen, and the street and water board elected. The assessed valuation in 1902 was \$100,550,026; the total public debt, excluding the water debt, \$16,205,325; the sinking fund is above \$3,000,000. The expenditures are about \$8,000,000 a year. The largest single item is \$460,000 for schools.

The population in 1850 was 6,856; 1860, 29,226; 1870, 82,546; 1880, 120,722; 1890, 163,003; 1900, 206,433. Of these 3,704 were colored, and 58,424 foreign-born, 19,314 Irish, 18,820 German, 4,642 English, 3,832 Italian.

The site of the city was used only as farming land till into the 19th century despite its remarkable position. In 1802 the entire population was 13 in one house with outbuildings; this was on Paulus Hook, the point opposite the Battery, named after the Dutchman Michael Pauw, who formerly owned it. Here in the Revolution the American fortifications had been taken by the British, and retaken and destroyed in a most brilliant action by "Light Horse Harry" Lee. In 1804 the "associates of the Jersey Company" bought the land, and laid it out in streets, incorporating it as a village with a board of selectmen. In 1820 it was incorporated as the "City of Jersey," still with a board of selectmen; in 1838 it was reincorporated as Jersey City, with a mayor and aldermen. Repeated annexations have brought it to its present territory: Van Vorst in 1851, Hudson City and Bergen in 1869, Greenville in 1873. It obtained a new charter in 1889. Consult: McLean, 'History of Jersey City' (1895); Eaton, 'Jersey City and its Historic Sites' (1899).

Jersey, Island of, the largest and most important of the Channel Islands, lying in the English Channel, and belonging to Great Britain. It is 12 miles long and from 4 to 7 miles wide, and has an area of 45 square miles. The distance to the coast of France is about 12 miles. The interior is mostly table-land and is well-wooded. The principal town is Saint Helier. The island is famous for a breed of cattle. Pop. (1901) 52,796.

Jersey Prison Ship, a notorious, unseaworthy ship, lying in New York harbor from 1776 to 1783, and used by the British as a prison for captured American sailors. Over 11,000 are said to have died of cold, starvation, and inhuman treatment.

Jer'seyville, Ill., city and county-seat of Jersey County, on the Chicago & A. and the Chicago, P. & St. L. R.R.'s, 66 miles southwest of Springfield. It was settled in 1839, incorporated in 1867, and adopted a new city charter in 1897. It has a public library and court-house,

and being the centre of a rich agricultural district, has an established trade in produce, fruit, grain and live-stock. The waterworks are owned by the city. Pop. (1900) 3,517.

Jerusalem (Greek *Hierousalem*. Old Hebrew pronunciation, *Yurushalem*. Tel-el-Amarna tablets, *Uru-sa-lim*; Assyrian monuments, *Ur-sa-li-im-mu*. Meaning certainly "city of Salim"; meaning of *Salim* disputed—probably an Assyrian god; usually assumed as Hebrew "peace," but the name antedates Hebrew. The Greek and Latin *Hierosolyma* is a corruption, from the erroneous supposition that the first syllable is Greek *hieros*, sacred. Hadrian renamed it *Aelia Capitolina*, and its official name was long *Aelia*, even Arabicized into *Iliya*; the Greeks called it *Kapitolias*. Arabic name, *Beit el-Makdis*, or simply *el-Mukaddas*, modern vernacular *el-Kuds*, "the sanctuary," or *el-Kuds esh-sherif*).

The "Holy City" is 33 miles from its port of Jaffa on the Mediterranean, 15 from the Dead Sea, 18 from the Jordan, 19 from David's first capital, Hebron, and 34 or 35 from the old kingdom of Samaria: the pregnant Hebrew history was transacted in the space of a county. It is 126 miles from Damascus. The position of the dome of the Church of the Holy Sepulchre is lat. $31^{\circ} 46' 45''$ N., lon. $35^{\circ} 13' 25''$ E. The city lies in the midst of an infertile, ill-watered district, once (under good government) made prosperous by irrigation, now blighted by Turkish possession. The rainfall is about 23 inches. The climate is hot and irregular—rising to 112° and not sinking below 25° , with an annual mean of 62° —but not malarious; the city is unsanitary and plague-stricken, but from dirt, lack of sewerage, bad water, and unhygienic habits. The only natural water-supply (the drainage sinking in the soft limestone) is from the Virgin's Spring (Gihon), an intermittent natural siphon on a dolomite floor, in a rocky cave 12 feet deep in the face of the eastern ridge; this was carried by a rock and masonry conduit to the rock and masonry Pool of Siloam, 52 x 18, and thence to another, the Old Pool; a shaft within the walls led down to a rock channel communicating with the spring. At present the water-supply is from rain-tanks or "pools," in and out of the walls. The remaining one of three old aqueducts, which carries water when in repair, was built by Pilate. There is little trade except that of local shops for supplying tourists; and the manufacture is chiefly of souvenirs, as olive-wood and mother-of-pearl articles. Indeed, as a commercial location it never possessed any merits, and its greatness was due to original political situation, and partly to its very defects. It is connected with Jaffa (west), Bethlehem and Hebron (south), and Jericho (north) by carriage-roads; and in 1892 a narrow-gauge railroad to Jaffa, with a circuitous course of 54 miles, was opened by a French company.

Jerusalem lies on several hills, rising from a steep plateau (see below), and the floor and slopes of a valley between the two main divisions. The modern city, much less extensive than the old in its best estate, is a rough quadrangle surrounded by a very irregular wall, built in the 16th century by Solyman I., on the lines of the Crusaders' fortifications. It has nominally eight gates, two on each side; the

JERUSALEM

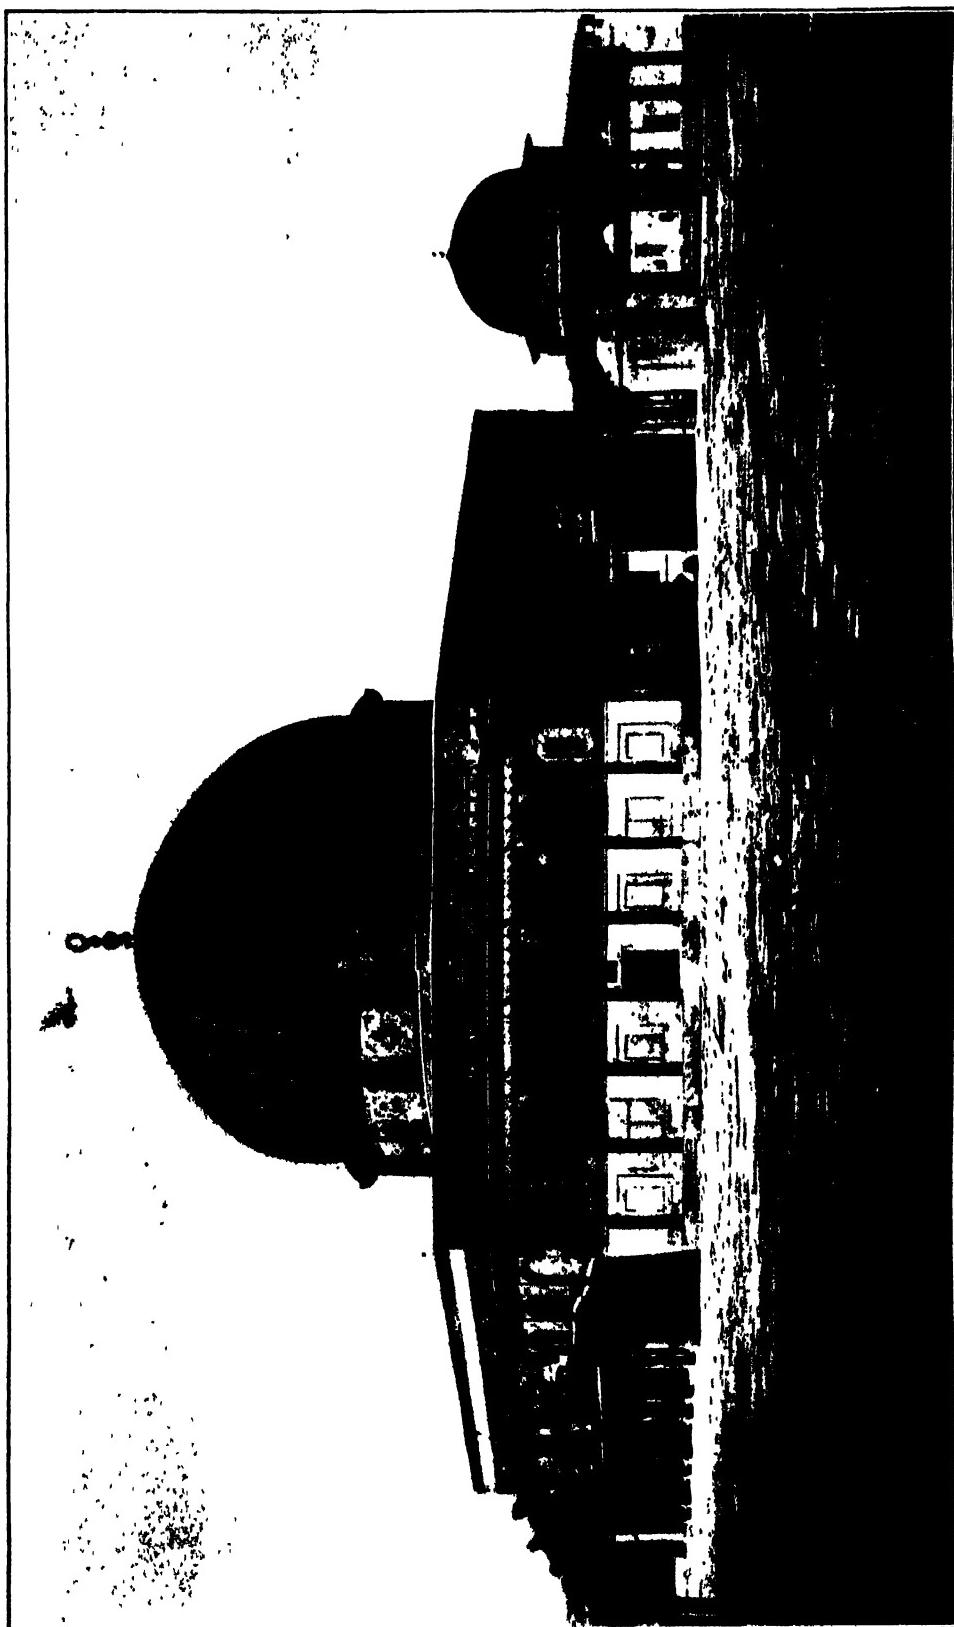

Jaffa and Abd-ul-Hamid on the west (the latter very recent), the Zion and Dung on the south, the Golden (closed up) and St. Stephen's on the east, and the Damascus and Herod's on the north. The city is unevenly divided, by the main street running from the Damascus gate south to near the Zion gate, and that running east from the Jaffa gate to the Haram-esh-sherif, into four "quarters" in which the great religious divisions are segregated: the Mohammedan, much the largest, on the northeast, adjoining the original holy places; the Christian next, on the northwest, where is the Church of the Holy Sepulchre; the Armenian on the southwest; the Jewish on the southeast. The streets are crooked, narrow, ill-made, and dirty, and the city has few except historical attractions; the stream of tourists, however, has developed civilized conveniences such as hotels, banks, mercantile establishments, etc. Several Jewish colonies have been settled in the environs; and since 1858 a quarter has grown up outside the walls on the northwest, approached by the Jaffa Gate, and containing consulates, Christian churches, schools, charitable institutions, etc., but not more sanitary than the old. The city is the capital of an independent sanjak, or Turkish administrative district, immediately subject to the government at Constantinople, and has an executive and a town council with representation of the great religious divisions. It is the seat of Roman Catholic, Greek Catholic, and Armenian patriarchs; the smaller Eastern churches have resident bishops; and till 1887 a joint Protestant bishopric was supported by England and Prussia, with alternate bishops, but on the death of the then incumbent Prussia withdrew from the arrangement, and England continues it alone. The population of the city at the last returns was as follows: Jews, 41,000; Mohammedans, 10,000; Christians, 12,800—made up of 6,000 Orthodox Greeks, 4,000 Roman Catholics, 1,400 Protestants, 800 Armenians 200 Uniat Greeks, and small bodies of Syrians, Copts, etc. Total, over 60,000.

The intense historical interest is centred on memorials of the time or localities of David and Solomon, and of the life and death of Christ. Of the former, the supreme interest is in the Haram-esh-Sherif, the site of the temple, and palace of Solomon and of the later temples. It is a walled area about 527 x 330 yards, with an elevated platform in the centre reached by steps; in the centre is the beautiful Kubbet es-Sakhra, or Dome of the Rock—a wooden octagon with sides of 66 feet 7 inches, decorated on the outside with marble and porcelain tiles, each of the four sides which face the cardinal points having a square gate surmounted by a vaulted arch. Just east of this is the Chain Dome, or David's Place of Judgment. Other domes of interest are near; but the next most notable structure in the Haram is the mosque El Aksa, at the south end. Within it are also a beautiful 15th-century fountain, a pulpit of the same date, a modern mosque called the Throne of Solomon, and the fortress of Antonia. Of the Christian monuments, the most noteworthy is the Church of the Holy Sepulchre, in the Christian quarter, originally built by Constantine the Great over the supposed place of the Ascension; after long oscillation of views, and for a time a general abandonment of the site as the true one, opinion is again favoring its authenticity. Most of the

present structure, however, dates only from the 19th century. There is a rotunda, with a dome 65 feet in diameter, above a small Chapel of the Sepulchre; a number of church buildings, said to include the site of Golgotha or Calvary; and 22 chapels. The Via Dolorosa, along which Jesus is said to have carried the cross to Calvary, follows the present street Tarik Bab Sitti Maryam from St. Stephen's Gate. Several modern churches and other institutions are also worth visiting; but the thronging Scriptural associations—besides those mentioned above, the Mount of Olives, the Pool of Bethesda, the Vale of Hinnom, etc.—overshadow all else.

Topography and History.—About a mile north of Jerusalem, the main north and south watershed ridge of Palestine turns to the west; while a spur called Olivet, having three pinnacles, runs first southeast 1½ miles, and then south 1¼ miles. The space between the two is occupied by a plateau sloping southeastward, and separated on each side from the bounding ridges by a ravine 300 to 400 feet deep, with steep and often precipitous sides. The eastern ravine, separating it from Olivet, is the "brook" Kedron or Kidron (Cedron), which was always a dry bed; the western is the Wady el-Rababi (probably the vale of Hinnom), which after skirting it on the west, turns east along the southern scarp of the plateau and joins the Kedron. Through this plateau from north to south runs a broader and much less deep and precipitous valley, the Tyropeon ("cheese-makers' place") 100 to 150 feet deep, thus dividing it into two uneven sections: the east ridge is continuous, and its northern part was the first occupied; the western part, the "new city," is divided by a lateral branch of the Tyropeon into two summits, a north and a south, connected by a narrow saddle separating also Tyropeon from el-Rababi. The general height may be stated as about 2,500 feet; the eastern ridge is 2,440 feet at the north, and descends southward; the western north summit is 2,490 feet, south summit 2,520. The accumulation of 3,000 years' rubbish, however, has greatly modified the contours of the hills and ravines, obliterating some minor ones altogether. The average depth over the rock levels is 30 to 40 feet, and in the valleys 70, in one case reaching 120.

This plateau, surrounded on three sides by steeply scarped bluffs and crested with hills, was a natural fortress; but it had two defects—it commanded nothing in particular, and its water-supply (one spring intermitting for hours or even a day or two, and that at the foot of a bluff) was very scanty. Probably at the first, as many times since, army after army marched around it, and left it untouched as of too little military significance. We first hear of it on the Tel el-Amarna tablets (about 1400 B.C.), when it is seemingly a little hill fort with a small garrison, possibly with a village also, and the capital of the "land of Jerusalem," apparently a small territory along the watershed. The king, Abd-Khiba, is a vassal of the king of Egypt, and begging assistance against the Khabiri (Hebrews?). Later it is a minor "Jebusite" citadel: Hebron, Bethlehem, Bethel, Gibeah, Jericho, are all more important. But when David undertook to form a consolidated Hebrew kingdom, Jerusalem had the transcendent merit that it lay on the border between Judah and the northern tribes, not historically identified with either; it

THE MOSQUE OF OMAR, JERUSALEM.

JERUSALEM OAK— JERUSALEM PLANK ROAD

was also fairly on the central line of communication, and convenient for action against the Philistines and the desert tribes at once. He made terms with the Jebusites and occupied the hill-fort of Zion on Ophel, near the only available water-supply. Possibly a village grew up on the eastern slope of the hill; but it was small, for the whole levy of Palestine was but 30,000 men (*2 Sam. vi. 1*), and other places held the trade. Solomon greatly increased the size of the town, and built a stone temple for Yahweh and a great palace. Under Rehoboam the place was captured by Shishak of Egypt; under Amaziah by Jehoash, and its walls partly leveled. During the palmy times of the northern kingdom it was held of small account except by the Judahites: it was only one of many places of pilgrimage down to Hezekiah's time, and the northern prophets ignore it and speak of Bethel, Gilgal, and Beersheba. With the fall of its northern neighbor, for the moment its importance and wealth increased; especially it became the one undefiled shrine, never mixed with rites of the native religions, the centre of Jewish religious life, the one place where sacrifice might be offered. In the later days of the monarchy the town spread beyond the east ridge into the Tyropoeon; a second town and a trading quarter grew up. For a long time after its destruction by Nebuchadnezzar in 586 the history is scant and dubious. It suffered heavily under the Persian empire; under Artaxerxes Ochus the temple *may* have been destroyed. Alexander's sacrificing in the temple is mythical; and in 320, Appian says, Ptolemy Soter destroyed the city. Then there was a time of peace and prosperity, culminating in the high-priesthood of Simon II. (219–199 B.C.); after a series of struggles between the Ptolemies and the Seleucids, in which the former took and garrisoned the place and the Jews helped drive out the garrison, the Seleucids obtained Palestine by treaty in 197. When Antiochus Epiphanes undertook to Hellenize Palestine in 169, he took the city, destroyed the walls, plundered the temple, and erected an altar to Zeus in place of that to Yahweh. Judas Maccabæus rebuilt the temple and the walls; again razed by the Greeks, they were again rebuilt by Jonathan. Under the Hasmonean dynasty it extended to the western ridge; there was a new palace and royal quarter of great splendor; the city became the metropolis of the Jewish world, and the one great pilgrim shrine. Then it became tributary to Rome, but at least still a kingdom governed by its own sovereigns; such it was when Jesus was born; but it shortly after became a province governed by a Roman procurator. The Roman system and Jewish feeling were incompatible, aside from any actual misgovernment; and a grand national revolt took place, which in 66 A.D. gained possession of Jerusalem. Vespasian was appointed to repress it; and in 70 A.D. his son Titus, after one of the most frightful sieges in history, with unimaginable horrors, took it, burned the temple, and leveled the city to the ground. Josephus says the city's population was 1,000,000, and Tacitus (probably from Josephus) 600,000; both are absurd, and Josephus' figures are always Oriental. From 30,000 to a maximum 45,000 may be estimated. It remained a ruin for many years. In 131 Hadrian visited the site and ordered it rebuilt; apprehending a restoration of pagan worship, the Jews broke out in rebellion under Bar-

Cochba; and Hadrian, not caring to set up a new centre of Jewish propaganda, made it a Roman colony called *Ælia Capitolina*, and forbade Jews to enter it on pain of death. Thence till the time of Constantine nothing is known of it; except as a Jewish shrine it was nothing. When the empire became Christian, Constantine's mother, Helena, induced him to cherish the seat of Christ's ministry and death; and he built the Church of the Holy Sepulchre (see above). Pilgrims flocked to Jerusalem from all parts, and it became the shrine of Christendom. Captured by Khosru of Persia in 614, it was retaken by Heraclius in 628; but in 637 was taken by the Moslems under the caliph Omar. The line of Arabian caliphs of different dynasties was succeeded by the Seljuk Turks. The Christians were oppressed, the sacred places defiled; to crown all, the overland caravan trade was cut off. Religious feeling and mercantile interest together roused Europe to the crusades, and Jerusalem was taken by Godfrey of Bouillon in 1099, becoming the capital of a Christian monarchy. This maintained a precarious existence till 1187, when the great Saladin put an end to it.

Among the many excellent works on the subject see, for topography and ancient history, the article *Jerusalem* in the "Encyclopædia Biblica," by W. R. and G. A. Smith and Col. Conder; also for topography, Col. Conder in Hastings' "Dictionary of the Bible." See also Warren and Conder's "*Jerusalem*" (1884, Palestine Exploration Fund), containing a large portfolio of plates; Wilson's "*Ordnance Survey of Jerusalem*" (1868), the basis of all modern work; De Vogue's "*Temple de Jérusalem*" (1864); Le Strange's "*Palestine under the Moslems*" (1890, Palestine Exploration Fund), the only book based on Arabic writers; Besant and Palmer's "*Jerusalem, the City of Herod and Saladin*" (4th ed. 1899); and the '*Quarterly Statement*' of the Palestine Exploration Fund.

Jerusalem Oak. See *GOOSEFOOT*.

Jerusalem Plank Road, Engagement near. After the battle of Cold Harbor (q.v.), 1–3 June 1864, Gen. Grant crossed to the south of James River, made unsuccessful assaults upon the Petersburg intrenchments, 15–18 June, and then determined to invest the city partially by a line of works toward the South Side Railroad, and by the evening of the 21st the Fifth corps rested its left on the Jerusalem Plank Road. The Second corps, followed by the Sixth, was moved across the road with the intention of seizing the Weldon Railroad at a point near Globe Tavern next day, and with the expectation of seizing also the South Side Railroad, and cutting Lee's communication with Lynchburg. At night the Sixth corps was in rear of the left of the Second. The orders for the 22d were that the Fifth corps should hold fast its position in front of the Confederate intrenchments, while the Second and Sixth swung to the right, and forward on its left, each division intrenching as it came into line. In the movement the corps commanders at first were directed to keep up connection, then they were ordered to move without regard to each other, each taking care of his own flanks. The Second and Sixth corps moved chiefly through densely wooded thickets; the Second on the right and near the Confederate works; the Sixth at right angles to the Second

JERVIS—JESUITS

toward the Weldon Railroad. Gibbon's division of the Second corps had swung in on the left of the Fifth and entrenched, Mott's division was intrenching, and Barlow's division, on the left, was not yet in position, when the last named was attacked. Gen. A. P. Hill had been sent down the Weldon Railroad to oppose Meade's attempt upon it. He had the three divisions of Wilcox, Mahone, and Bushrod Johnson. Leaving Wilcox to oppose the Sixth corps, which had not come up on the left of the Second, Hill, about 3 p.m., passed Mahone and Johnson through the opening between the two corps and struck Barlow in flank and rear, driving him back in confusion to the position from which he had advanced in the morning, and taking many prisoners. Mott's division, on Barlow's right, fell back precipitately, and then Hill struck Gibbon's left brigade in front, flank and rear, causing it to give way and abandon a battery of four guns. So sudden and unexpected was this attack upon Gibbon that the greater part of several regiments were captured with their colors. Gibbon made an unsuccessful effort to recover the lost portion of his line. Hill returned to his intrenchments, leaving some force on the railroad, and toward evening the Second corps was thrown forward; but it was not until next morning that it occupied the ground from which it had been driven, the Sixth corps, forming on its left, thrown back facing the Weldon Railroad, and about a mile from it. The Union loss on the 22d, confined almost entirely to the Second corps, was nearly 2,000, of whom about 1,700 were prisoners. The Confederate loss is unknown. Consult: 'Official Records,' Vol. XL.; Humphreys, 'The Virginia Campaign of 1864-65'; Walker, 'History of the Second Army Corps.'

E. A. CARMAN.

Jervis, jér'vís, John Bloomfield, American civil engineer: b. Huntington, N. Y., 14 Dec. 1795; d. 12 Jan. 1885. He was employed as axeman on the route of the Erie Canal in 1817; in 1819 became a resident engineer of the middle portion of the canal; was chief engineer of the Delaware and Hudson Canal and Railroad Company, 1825-30; and chief engineer of the Croton Aqueduct, 1836-43. In later life he was consulting and chief engineer of the Cochituate water works, Boston, and of several important railways. He built the Croton dam, the High Bridge at New York, and other notable structures. The town of Port Jervis (q.v.), N. Y., was named for him. He published: 'Railway Property'; 'Construction and Management of Railways'; 'Labor and Capital.'

Jesse, jés'ë, in the Bible stands at the head of the house of David, who was his son. While Saul was persecuting David he took refuge in the land of the Moabites, where Ruth the Moabitess, his grandmother, had lived. In the genealogy of Jesus Christ as given in the Gospels of SS. Matthew and Luke he is mentioned as one of the ancestors, as Christ in the New Testament is hailed "Son of David." This fact has suggested some of the most interesting creations of mediæval art, and what is called a "Jesse window" is a stained glass church window in which Jesse is depicted as the root of a tree which bears as its fruit David and other heroes and saints of the Old Testament, with

the infant Jesus in the arms of his mother on the highest branch.

Jesse, Richard Henry, American college president: b. Epping Forest, Lancaster County, Va., 1 March 1853. He was graduated from the University of Virginia in 1875, was dean of the academic department of the University of Louisiana from 1878 till its union with Tulane University in 1884, in which institution he was professor of Latin till 1891. Since January 1891 he has been president of the University of Missouri.

Jes'sop, Augustus, English Anglican clergyman and author: b. 20 Dec. 1824. He was educated at Cambridge and after taking orders in the English church was curate of Papworth St. Agnes, Cambridgeshire, 1848-54; head master of Helston Grammar School, Cornwall, 1855-9; and head master of King Edward VI.'s School, Norwich, 1859-79. He has been rector of Scarning, Norfolk, from 1879, and is an honorary canon of Norwich Cathedral. As a writer he became widely known by his 'Arcady for Better or Worse' (1881), studies of agricultural life in Norfolk; and among other works of his are: 'Studies by a Recluse'; 'Trials of a Country Parson'; 'The Coming of the Friars' (1885); 'John Donne.'

Jest Book, a compilation of witty sayings and practical jokes. The oldest known English jest book is 'A Hundred Mery Talys' (about 1525). The best known collection is 'Joe Miller's Jest Book, or the Wit's Vade Mecum' (1739).

Jesuit (jéz'ü-it) Relations and Allied Documents, The, a series of 72 volumes on the travels and explorations of the Jesuit Missionaries in New France (1610-1791). The original French, Latin, and Italian texts, with English translations and notes; illustrated by portraits, maps, and facsimiles, and edited by Reuben Gold Thwaites. A republication of great magnitude and importance. The very great value of the work is that of original materials of the most interesting character for the history of North America from 1611, the date of the first landing of Jesuit missionaries on the shores of Nova Scotia. The reproduction of documents takes them in chronological order. The execution of the work by translators, editors, and printers (at Cleveland, Ohio) is every way admirable; and its completion will make a monumental addition to American historical libraries.

Jesuits, a religious order of the Catholic Church whose members, like those of similar societies, solemnly bind themselves to aspire to perfection by leading a life of chastity, by renouncing the possession of all personal property, and by obedience to lawful superiors in all that does not contravene the law of God. A certain number of them add a special vow of obedience to the Pope. They are called the Society or Company of Jesus, the latter designation expressing more correctly the military idea of the founder, which was to establish, as it were, a new battalion in the spiritual army of the Catholic Church. There are no female Jesuits, nor are there crypto or secret Jesuits. Romances are mostly responsible for such myths. Nor does the Society form, as is sometimes fancied, a sort of sect within the Church. R. W. Thompson, ex-secretary of the United

JESUITS

States navy, in his 'Footprints of the Jesuits' asserts that they are such, and independent of the pope, and in one instance he accuses them of being idolaters. As a matter of fact the Society of Jesus has always inculcated ardent devotion to the pope, the most uncompromising orthodoxy and an intense Catholic spirit. The descriptions of Jesuits as crafty, unscrupulous men constantly engaged in dark plots against all who stand in their way, are inventions of their enemies and have no foundation in fact. Finally they are not monks, as they are sometimes described. Technically they are classed among churchmen as clerics, living according to a rule and are properly regular clerics.

The special object of the Society beside the personal sanctification of its members is to propagate the Christian faith chiefly by teaching and preaching. Their teaching is restricted mainly to the higher studies, and includes literature, mathematics, science, philosophy, theology, and the cognate branches. Their preaching addresses itself to all classes, but, by predilection, and at stated periods in a Jesuit's life, by express injunction, it concerns itself with catechizing the ignorant, and instructing the inmates of hospitals and penal institutions, while it addresses itself also to more cultured and spiritual audiences. One special and characteristic feature of its ministry is known as the "Spiritual Exercises" or "Retreats" which it may be regarded as having introduced, or revived in the modern church, and are now a universal ascetic practice with the clergy and religious communities as well as with a considerable number of the laity. A "Retreat" is a withdrawal from worldly occupations for a more or less protracted period in order to scrutinize the state of the soul and to take means to amend one's life, or to strive for higher Christian perfection. The method of these "Exercises" is laid down in a small manual written by the founder of the Society. The book itself, which is at first sight fragmentary, and only suggestive in its character, is not easily understood or explained except by those who are trained to interpret it.

The Society was founded by Ignatius Loyola, a Spanish nobleman, who after being disabled in fighting for his country, betook himself to the solitude of a cave near the little town of Manresa, Spain, where he passed some months in prayer and severe bodily austerities. Later, desirous of working more effectively for the salvation of his fellow men, he determined to become a priest, and for that purpose studied in the universities of Alcala and Salamanca, and finally in Paris, where he gathered about him six companions, among whom were Francis Xavier, the future Apostle of Japan, Peter Faber, whom, with Ignatius and Xavier, the Church was to honor subsequently as a saint, and also Salmeron and Laynez, who were conspicuous luminaries at the Council of Trent which was then about to be convened against the doctrines of Luther, Calvin, and others who had just then arisen.

On 15 Aug. 1534 these seven men organized themselves into a society, and pronounced their vows in the crypt of a little chapel in what is now Rue Antoine, a short distance below the crest of the hill of Montmartre in Paris. It was only six years afterward that Pope Paul III. gave them and the others who had joined them meantime his solemn approval.

The peculiarities of their organization were the occasion of much antagonism at the very outset on the part of some of the most eminent men of the Catholic Church. The Inquisition strongly suspected its purposes and doctrines. The name of the "Society of Jesus" was objectionable to Pope Sixtus V. Unlike other orders they were to be dispensed from reciting the divine office in common, and were to wear no distinctive habit. The length of probation and the general structure of the Society were unusual. The members were first the professed who were relatively few. In them the governing power resided, and they were distinguished by a special vow of obedience to the pope. Then came the spiritual coadjutors, or priests, who did not take the special vow of obedience to the pope. Preparing for either category were the students or scholastics, and lastly there were lay brothers who were to devote themselves to domestic duties. Those who applied for admission were to pass two years of noviceship, and not one as in other religious orders, and were then admitted to what are called simple vows which could be easily dispensed with by proper authority if the subject were subsequently found unfit. Following the noviceship, two years were given to a review of the classical studies; then came three years of philosophy, mathematics, and the physical sciences; five years of college teaching and four years of theology, to end only with another year of seclusion and prayer, after which the candidate was permitted to take the solemn vows which bound him irrevocably to the order as a spiritual coadjutor or professed. The probation of the lay brothers was protracted to ten years. The Jesuit renounces by vow all ecclesiastical dignities, and accepts them only in unusual circumstances and by express command of the pope, under pain of sin in case of refusal. As the establishment of the Society of Jesus coincided with the Protestant Reformation the efforts of the first Jesuits were naturally directed to combat that movement. Under the guidance of Ignatius so much success attended their work in Germany and other northern nations, that, according to Macaulay, Protestantism was effectually checked. In England where Elizabeth had inaugurated a movement against her Catholic subjects, and previous to that under Henry VIII. the Jesuits stopped at no danger to go to the rescue of their brethren in the faith; and what they did there was repeated in other parts of the world. "In spite of oceans and deserts, of hunger and pestilence, of spies and penal laws, of dungeons and racks, of gibbets and quartering blocks, the Jesuits were to be found under every disguise, in every country; scholars, physicians, merchants, servingmen, in the hostile court of Sweden, in the old manor houses of Cheshire, among the hovels of Connaught arguing, instructing, consoling, animating the courage of the timid, holding up the crucifix before the eyes of the dying."

Such is the testimony of Macaulay, a Protestant historian. Though many died as martyrs on the scaffolds and in the prisons of England and elsewhere, yet their skill in evading detection as well as their courage in living in the midst of their enemies and their great success in winning converts well explain the hatred with which they were regarded in Protestant countries from the very beginning, while it gives us

JESUITS

the historical origin of the tradition of cunning and deceit which has always been associated with the name of Jesuit.

Under James I. they were accused of complicity in an alleged attempt to blow up both houses of Parliament, and though clearly proven to be innocent of the charge, Father Garnet, who was said to have been cognizant of the plot, was executed, and the accusation is still believed. Guy Fawkes' Day commemorates the event and perpetuates the calumny. It is probably in connection with this occurrence that the supposed Jesuit doctrine of "the end justifying the means" was first accredited to them and the accusation made that "it was their office," as Macaulay assures his readers, "to plot against the thrones and lives of apostate kings, to spread evil rumors, to raise tumults, to inflame civil wars and to arm the hands of the assassin." The first one who is accused of formulating the doctrine of the end justifying the means is Father Waggermann of Innsbruck 1762. Even the murders of Henry III. and Henry IV. of France were ascribed to them, and under Charles II. of England six Jesuits were accused by Titus Oates of conspiracy and put to death. These and other charges have been repeatedly disproved, yet writers of romance, and even writers of history, never fail to find readers credulous enough to accept them as true.

While the Jesuits were propagating the faith in Europe they were sending missionaries to every part of the world to preach the Gospel to heathen nations. Greatest of all these apostles was St. Francis Xavier whom all Protestant writers unite in glorifying and whom the pagans almost worshipped as a deity. His name is still mentioned with enthusiasm among the pagans in Japan and the Occident. The conversions which he effected and the miracles he wrought almost defy belief. It is a testimony to the solidity of his teaching that although Catholicity was apparently obliterated in Japan by a series of bloody persecutions, the French missionaries who entered the country in 1860 found 30,000 Japanese Christians there. In spite of the absence of priests, the doctrines and practices received from Francis Xavier which meant death to profess openly had been handed down from father to son for a period of nearly 300 years. One blot on the reputation of the Society in this field was the shameful apostasy of one of their superiors; but he atoned for his sin by a subsequent martyrdom.

In America the French Jesuits undertook the task of evangelizing the Indians, and at one time had 3,000 civilized and christianized Hurons under their control. In what is now New York, Father Jogues was cruelly tortured and slain on the banks of the Mohawk in 1646. In 1649 Garnier, Daniel and others were shot to death; and at the same time De Brébeuf and Lallement were burned at the stake while their flesh was slashed with knives and their hearts cut out and eaten by the Indians of Lake Superior. Others died from want and exposure. It was Jogues who discovered Lake George to which he gave the name of Lac du St. Sacrement. Later on Le Moyne came upon the salt springs near Syracuse. Marquette discovered the Mississippi which he named the River of the Immaculate Conception. He explored it as far as the mouth of the Arkansas, and returning home was the first white man with his companions to

travel over the territory of what is now the city of Chicago. Wisconsin has erected a statue to his honor. Other Jesuits reached the Pacific coast and established the missions of California which they handed over to the famous Franciscan Junipero Serra when the Society was suppressed. English Jesuits had come over with Lord Baltimore; and before that five Spanish members of the order had been slain by the Indians on the banks of the Rappahannock. The "Relations" of the French Missions have been recently published by an American publishing house and form 72 volumes of missionary and scientific information which the "Atlantic Monthly" considers the most precious material that could be desired for the history of this country. Similar records have been kept by the Jesuits of other nationalities. Marquette's diary and maps of the discovery of the Mississippi decided the controversy between France and England about the possessions of the western territory.

The missions of South America conducted by the Spanish and Portuguese Jesuits were remarkable in their character and extent. Father Ancheta, a native of Brazil, was particularly distinguished for his missionary success as well as his gift of miraculous powers. Peter Claver devoted himself to the thousands of negro slaves who were brought to the port of Cartagena. Other Jesuits traveled through Chile and Peru. Seventy of them on their way thither were said to be killed by Calvinists who intercepted them at sea. But their most famous work was what are known as the 'Reductions' or Christian Commonwealths of Paraguay. The description of these missions forms one of the most brilliant chapters of Chateaubriand's "Génie du Christianisme;" but a recent work entitled 'A Vanished Arcadia' by Cunningham-Graham gives a more reliable and scholarly account of what was accomplished there. Voltaire says: "When in 1768 the missions of Paraguay left the hands of the Jesuits, they had arrived at perhaps the highest degree of civilization to which it is possible to conduct a young people."

"For nearly two hundred years they controlled a district as large as France," writes Cunningham-Graham, "where they had established 32 towns in which there were 160,000 Indians whom they had converted and civilized, teaching them agriculture, the mechanical arts, commerce, and even forming among them a small army of defense. The annual income of the country was about 1,000,000 reales. The missionaries were finally expelled by Charles III. and the country fell back into its primitive condition of a tangled wilderness."

The reasons of their expulsions were first the jealousy of the Spaniards at being excluded from the territory, secondly the anger of the colonists at being prevented from enslaving the Indians, and thirdly the ungrounded suspicion that there were gold mines in the missions. An impression in the royal mind that the Jesuits had reflected on the circumstances of his birth made him an easy instrument in the hands of the enemies of the Society. "Curious as it may appear," writes Cunningham-Graham, "the bitterest opponents of the Jesuits were Catholics, and Protestants have often been their apologists. Buffon, Raynal, and Montesquieu with Voltaire, Robertson, and Southey have written favorably of the internal gov-

JESUITS

ernment of the mission and the effect it produced. When the Spanish general was sent to dispossess them, he set about it with more preparation than Cortes or Pizarro made for the conquest of Mexico or Peru. But there was no resistance, and all the wealth the fathers had was the poor clothes on their backs." The destruction of these missions was probably a part of the prearranged plan for the annihilation of the whole Society.

The missions of Japan which Francis Xavier had inaugurated continued after his death in spite of the fierce persecutions in which many Jesuits perished. He had been unable to teach China and died on a lonely island off the coast. Ricci, Verbiest, Schall and others carried out his project and became the advisers of the emperor as well as his astronomers, mathematicians and mechanicians. The great bronze astronomical instruments carried off by Germany on the occasion of the recent invasion of that country by the allied powers of Europe were the work of the Jesuits of the 17th century. As soon as the mission was started, great numbers of Jesuits came from Europe, half of them generally dying on the passage. In 1661 they possessed 151 churches and 38 residences there, and had written as many as 131 works on religion, 103 on mathematics, and 55 on physical and moral sciences.

Numberless other missions were established elsewhere; de Nobili for instance lived like a Brahman in India to reach that particular caste, and was almost suspected of apostasy for doing so. He is said to have made 100,000 converts. Jesuits overran the whole Indian peninsula and crossed the Himalayas into Tibet. Africa had long before been penetrated, and one of the first members of the Society was Patriarch of Ethiopia. The present explorers of the Dark Continent find remnants of former missions far in the interior. They had gone from Mexico to the Philippines in the earliest days; they had entered Tartary and Lebanon, and when their own efforts were thwarted they induced others to take their places. Thus De Rhodes, a Jesuit expelled from Japan, founded the Société des Missions Etrangères, a body of secular priests who have given a great number of saints and martyrs to the Catholic Church.

While the Jesuits were engaged in missionary work among the uncivilized peoples of the world they erected splendid churches all over Europe, and furnished such orators to the pulpit as Bourdaloue in France, Vieyra in Portugal, and Segneri in Italy. The "Book of Spiritual Exercises," according to St. Francis de Sales, "has converted as many souls as it has letters." But their apostolic work was not restricted to preaching, and we hear of a single French Jesuit who during his 40 years of ministry had established as many as 146 hospitals for the poor. They founded orphan and Magdalen asylums. They were the confessors of kings and princes and delegates of the Holy See, but they extricated themselves from these honorable charges as soon as it was possible to do so. At the time of the suppression they controlled and directed the majority of the ecclesiastical seminaries of Europe.

The success of the Society in the work of education forms a great chapter in its history. Their method is found in what is known as the "Ratio Studiorum" or Plan of Studies. It is

a complete system of pedagogy and covers the whole field from the lowest class of grammar up to philosophy and theology. The plan was first conceived by Ignatius himself, and subsequently elaborated by one of his successors, Claudio Aquaviva. Compayré, one of the chief pedagogists of the present time, denounces it as a mere system of memorizing. Bacon says of it: "never has anything more perfect been invented." Their colleges at one time covered all Europe, and in the single school of Louis le Grand they had as many as 3,000 students. Kings assisted at its public academic exercises. Among their scholars they can claim some of the greatest men of modern times, as for instance Popes Gregory XIII., Benedict XIV., Pius VII., St. Francis de Sales, Bossuet, Fleury, Flechier, Montesquieu, Malesherbes, Tasso, Galileo, Corneille, Descartes, Molière, Mezzofanti, Muratori, Buffon, Gresset, Canova, Tilly, Wallenstein, Condé, the emperors Maximilian, Ferdinand and others. Even Voltaire was one of their pupils. The disturbed conditions of modern times prevent a similar brilliant showing, but many of the most distinguished Catholic churchmen of to-day have studied in their schools, and notably Leo XIII. who was trained by them from his college classes to the end of his theological course.

Within their own ranks they have furnished great scholars in all branches of philosophy, theology, history, philology, literature, and science. It is sufficient to name such men as Suarez, De Lugo, Bellarmine, Toletus, Lessius, à Lapide, and to note that the treatises of Jesuit writers form the text-books in all the theological seminaries of the Catholic Church to-day. They have written in almost every language and on every conceivable subject, and the mere catalogue of their writers, though not yet complete, already fills more than seven large quarto volumes. Their missionary enterprises were never disjoined from scientific investigation.

Their history is marked by ceaseless activity in launching new schemes for the spread of the Catholic faith, and by absolute fearlessness in opposing error regardless of any consequences to themselves. These two characteristics may explain why even by some Catholics they are regarded as a disturbing element in the church. One of their most noted disputes with churchmen was with the Dominicans on grace, during which the Jesuit doctrine of grace was formulated. The contest lasted for nine years, and although great theological learning was adduced on both sides a truce was imposed by the Pope without any decision being arrived at. Of far greater consequence was their war with the Jansenists. It was chiefly on this occasion that the Society was accused of laxity in their moral code and that their great antagonist Pascal won fame by his "Lettres Provinciales," which like the famous "Monita Secreta" of former times purported to be the private instruction of superiors to members of the order. After this contest their expulsion from France was an easy task, as the Jansenists wielded great political influence and were backed by the irreligious element which was growing rapidly there.

They have been expelled over and over again from almost every Catholic country in Europe, always, however, coming back again to

JESUP—JESUP NORTH PACIFIC EXPEDITION

renew their work when the storm had subsided; and this fact has been adduced as a proof that there is something iniquitous in the very nature of the organization. Worse still in 1773 the entire order was suppressed by a brief of Pope Clement XIV. and all their goods confiscated. They then numbered 24,000 members and had establishments in all parts of the world and flourishing missions, all of which were immediately destroyed, but not one Jesuit uttered a word of complaint or protest. What is remarkable is that while Catholic popes expelled them they were protected by the schismatic Catherine of Russia, and the Protestant Frederick of Prussia, the friend of Voltaire. This very protection was urged as a reproach against them and as a proof of their guilt.

With the exception of the disastrous financial speculation of Lavalette, which was the sin of an individual and not imputable to the entire Society, as commercial transactions were absolutely prohibited by the statutes, the Society is proved to be guiltless both in its partial suppressions and in its total abolition. This is clear from the very brief of Clement XIV. which dealt the blow. In that document all the charges are enumerated, but not one is pronounced to be true. The Society was suppressed as a political necessity and for nothing else. The encyclopædist of France regarded it as their most redoubtable opponent and had vowed its destruction. "Destroy the Jesuits," said Voltaire, "and we shall make an end of the beastly Church." In this work the Bourbon kings had to be enlisted. Madame de Pompadour, the king's mistress, whom the Jesuits had refused to absolve, influenced Louis XV.; the Spanish and Portuguese ministers wrought on the fears of their sovereigns by forged documents containing threats and plans of assassination, and when all was ready the monarchs gave the pope a choice of suppression of the Society or schism. The pope yielded, and is said by Pius VI. and Pius VII. to have lost his mind in consequence. The vindication of the Society came immediately. The very pope who suppressed them approved of their corporate existence in Russia. Pius VI. who succeeded him in the following year re-admitted them into Italy, and Pius VII. on the fall of Napoleon re-established the Society in all its integrity on 7 Aug. 1814.

Since its rehabilitation the Society has continued to increase in spite of constantly increasing difficulties. In the beginning of 1902 it counted 15,231 members, of whom 6,743 were priests, and 4,542 scholastics in preparation for the priesthood. The general of the Society is Louis Martin, a Spaniard, who was elected in 1893. In the United States they number about 1,800, with colleges and churches in the principal cities and with flourishing missions among the Indians of the Rocky Mountains and Alaska. In Cuba and the Philippines their schools have achieved remarkable success, and the great meteorological observatories of Havana and Manila were established and are at present controlled by them. The chief houses for studies for the American members of the order are at Woodstock, Md., St. Louis, Mo., and Montreal, P. Q.

In some countries of Europe the same hostility still pursues them. In the revolutions of 1830 and 1848 their houses were closed and the members driven out of the country. In the

Kulturkampf inaugurated by Bismarck they were the first victims, and all the efforts of the Centre party have hitherto failed to secure their re-entrance into Germany. Similarly they were the first to be struck in the present religious persecution in France. On the other hand they have been the recipients of countless marks of esteem and affection on the part of Leo XIII., and he has placed the stamp of his approval on the Society by adding very many new names to its already long list of canonized saints and martyrs.

T. J. CAMPBELL, S. J.

Jes'up, Morris Ketchum, American banker: b. Westport, Conn., 21 June 1830. He was engaged in banking in New York 1852-84, but retired from business in the latter year. In 1881 he became president of the New York City Mission and Tract Society, for which he subsequently erected the DeWitt Memorial Church in Rivington Street, in memory of Rev. T. DeWitt, his father-in-law. He was made president of the Five Points House of Industry in 1872; was a founder of the Young Men's Christian Association, of which he was president in 1872. He was also elected president of the Metropolitan Museum of Natural History in 1881, and of the New York Chamber of Commerce in 1899. To the Metropolitan Museum of Art he has given a collection of native woods valued at \$100,000; to the Woman's Hospital in New York city, \$100,000; and to Yale University and Williams College, large sums likewise.

Jesup North Pacific Expedition, The, an American organization for archæological research, supported by Morris K. Jesup (q.v.), and conducted under the auspices and direction of the American Museum of Natural History. The work began in 1897 in British Columbia. In that year Prof. Harlan I. Smith began to dig in the Thompson River district. In successive years he worked a little farther east, and also around Puget Sound, and down the west coast of Washington. Results of these explorations have been compared and conclusions drawn as to the class of people who inhabited these regions in prehistoric times. Very interesting differences were found among them. Some were more highly developed than others. In particular, one small section east of the city of Vancouver was found to reveal traces of a people much more highly developed than any others of the section, and interesting in many ways to the archæologist. Some of the regions explored revealed the remains of coast tribes; others of interior tribes. At some points these characteristics merged, producing a different

JESUS CHRIST

type. New discoveries of one season explained things not understood in previous explorations. So to gather up missing links and further elucidate the whole region, especially that interesting little people near Vancouver, it was necessary to take up some new territory and thoroughly explore it. Prof. Smith, therefore, went into the Yakima Valley in northern Washington in 1903. On the map this section does not look far from the Thompson River district in British Columbia. And when one reflects how very similar are the white people now inhabiting the two sections and how near the two districts are, it is interesting to find that the prehistoric peoples inhabiting them differed at least as much as the Spanish and the Germans, according to Prof. Smith's conclusions. Not only their culture, but their skulls were different, as known by the skeletons brought back by the expedition. These ancient tribes seemed to have lived, each in its little nook of coast or river valley, for unnumbered ages, never going to see what was on the other side of the mountain; developing each its own little morsel of civilization in its own little way, its life and culture and development modified by the little corner of the earth's surface in which it sat down, seemingly to stay forever. Sometimes shell heaps are found miles in length, and with tree stumps six feet in diameter standing on nine feet of these layers, of which each is only an inch or two in thickness. It took a good many generations of Indians to pile up those successive layers with the shells from their shell-fish dinners. A stump of Douglas fir, over six feet in diameter, stood on a shell heap eight feet below the surface which contained human remains. The tree indicated an age for the top layers of more than 500 years. The material brought back included carved and sculptured pipes, stone mortars, pestles, and sinkers, bone implements used on spears, deer antlers used as handles, stone adzes differing from those found anywhere else, bone needles, shell ornaments, and the like. The expedition also found many paintings and sculptures on rock walls, which were photographed.

Jesus Christ, the founder of the Christian religion. Four documents dating from the second half of the 1st century, the "Gospels," give some account of the life of Jesus, chiefly confined to his brief public work and death. Beyond what they give little is known as to his history. Some of the most important facts are referred to in other writings of the New Testament, especially in the letters of Paul; secular history contains mere references to him; a number of later writings, the so-called "Apocryphal Gospels," purport to give additional information, but they are fictitious and worthless; and beyond a very few sayings which were probably rightly attributed to Jesus, called "Agrapha," tradition has preserved nothing of value which was not embodied in the Gospels. These narratives vary, but are rarely inconsistent: usually they may best be regarded as complementary, and the picture of the life and work of Jesus which may be drawn from them has been accepted as trustworthy throughout Christendom in all centuries, and while on many points confirmation from other sources cannot be expected, the investigations of impartial scholars have rather confirmed its accuracy than invalidated it.

Birth and Parentage.—According to the Gospels, Jesus was born in the family of a carpenter named Joseph, living in Nazareth (q.v.), a small town in southern Galilee. Descent from the line of kings of Judah which began with David is positively claimed for Joseph, and, as some understand the genealogical tables, for Mary, his wife, as well, but during the centuries of national disaster the descendants of David seem to have sunk into poverty and inconspicuousness. While Nazareth was the family home, the birthplace of Jesus was Bethlehem (q.v.), the village of Judea in which David himself was born, a fact which is explained by mention of a census said to have been made under Roman authority while Quirinius was Roman representative in Judea, and to have required that all citizens should be enrolled at the original home of the family. Though no other record of this enrollment has yet been discovered, late discoveries make the fact seem more plausible than it was formerly regarded by some scholars.

The Gospels represent Jesus as born of a virgin, conception having been due to special divine power. The date of his birth cannot be given with certainty as to day, month or even year. Since it must have somewhat preceded the death of Herod (April 4 B.C.), it probably occurred sometime in the year 5 B.C. (possibly 6). It is reported that Mary, in a village strange to her, and at the time overcrowded with visitors, could find no place to lay her new born babe but in a manger. But at the presentation in the Temple for the offering of the sacrifices which Jewish ritual prescribed after childbirth, the infant was joyously hailed by Simeon and Anna, aged saints profoundly possessed by the common Messianic expectation of the nation at that time, and, as shepherds from not far away had come in the night of his birth in obedience to a vision of angels, so, later, the Magi (q.v.) from afar guided by a star sought the child to offer him obeisance and rich gifts. This visit of the Magi, however, made Herod aware of the birth of a child who might grow up to be a dangerous rival of the dynasty which he hoped to found, and it is handed down to us that unable to trace it he ordered the slaughter of all the infants of the village up to the age of two years. But his parents, divinely warned, had taken the child to a safe refuge in Egypt, where they remained till the death of Herod, presumably only a short time. If they returned in the expectation of bringing him up in the ancient home of his line, they were deterred by fear of Archelaus who had succeeded his father as ruler in Judea, and consequently they turned aside to Nazareth where they were secure under the milder rule of Antipas.

Early Manhood.—Of the life of Jesus up to manhood nothing is known, except the mere mention of his visit to Jerusalem when 12 years old. It can be supposed only that he was subjected to the natural influences of a religious Jewish family of the time, of synagogue and of school, of a village at once quiet and yet close to the thronging traffic on one of the great thoroughfares of that age, and finally of the work of a carpenter, for such he is said to have been, till 30 years of age. It was about this time, possibly in the year 26 (or 27) that John the Baptist (q.v.) began his public career, and at once aroused great religious and patriotic fervor in the nation.

JESUS CHRIST

The careers of neither John nor Jesus are intelligible without an understanding of the expectant attitude of the Jewish people in the 1st century. The ancient prophets of the nation had centuries earlier foretold a renaissance of the Hebrew kingdom under a descendant of David, through the generations this hope smouldered in the hearts of the people, only fanned to a brighter flame by blasts of persecution and national disaster, and the whole influence of the sect of the Pharisees (q.v.), popular and powerful out of proportion to their numbers, increased its intensity under Herod and his successors. The people were ready to be fired by the proclamation so strikingly made by the gaunt desert-dweller that the fulfilment of the national hopes and dreams was near: "The kingdom of heaven is at hand." The preaching of John was, however, no less moral and religious than patriotic. His message was "Repent"; let the nation prepare by penitence to meet the king coming in his kingdom. This prophetic voice set the country in a blaze. Throng gathered to listen to the new preaching and by a striking symbol, a plunge in the rushing Jordan, to pledge themselves to the new movement. After a time Jesus joined the crowds which attended the ministry of John. It is impossible to say what connection may have existed between John and Jesus. Not only were their families related, but there may have been constant intimacy. John, however, based his later testimony as to Jesus, not at all on his own knowledge of him, but entirely on the divine revelation which was his commission. Jesus offered himself for baptism, insisting that the reluctant preacher should perform the rite, and thus pledged himself to the Coming Kingdom. While it is not claimed that the wonders which attended the baptism were known to others than John and Jesus himself, the story of the Gospels is that a heavenly voice asserted the Messiahship of Jesus, and that with the appearance of a dove the Divine Spirit came to him. The conviction of his mission to his nation and the world was no new thought to the carpenter of Nazareth, and it was with this thought in mind that he recognized the significance of the Baptist's public appearance, joined his auditors, and submitted to the ordinance which he administered. Yet it is not surprising, on the other hand, that he felt constrained, when his own conviction was confirmed, to seek the desert of Judea that alone he might adjust himself to the new responsibilities and burdens of the mission which he must undertake. Amid the solitude of the barren rocks and gloomy caves of that desolate region he meditated and struggled. Of this period we know only the striking story, necessarily autobiographic in origin, in which he depicts the struggles which he underwent as due to Satan's influence. Temptations thus forced in upon him to selfish use of his power, to sensational fanaticism and to compromise with evil in order to advance his ends, were successively resisted, and at the end of 40 days he came forth the victor in all these spiritual conflicts, ready to enter actively on his ministry.

The Ministry.—Jesus returned to the Jordan where John was still at work, and aided by his testimony associated with himself a little group who instinctively recognized in him a future leader of the nation. He went from there first

to his home district, where he and his companions were guests at a wedding at Cana, a little town which has been hallowed in all the Christian centuries by John's report of the changing of the water into the wine needed for the entertainment of the company in the prolonged merrymaking incident to such an occasion. Then, as it was near the Passover time, Jesus, accompanied by his mother and brothers as well as his few followers, after staying a short time at Capernaum, went on to Jerusalem. How long he remained in or near the capital city must continue a matter of inference from a few doubtful phrases, but it seems most probable that he remained in Judea for some months, perhaps from April to December. The chief events ascribed to this period are the first cleansing of the Temple and the night interview with the influential rabbi, Nicodemus, and while the effect on city or nation was not great, it was presumably at this time that Jesus formed the strong friendships in Judea, to which incidental reference is often made afterward. The closing of this portion of his ministry seems to have been due, on the one side, to the hostile jealousy of the dominant Pharisees which would hinder success in Judea, and, on the other, to the imprisonment of John the Baptist which made it possible for Jesus to work in Galilee without what might have seemed competition, and, indeed, made it advisable for him to take up the work which John had been obliged to drop.

On his return to Galilee Jesus soon recalled his disciples, who, if they had accompanied him throughout his work in Judea, had scattered for a time to their homes, and associated himself with them in a companionship which was thereafter unbroken till his death. He made Capernaum the central point of his ministry, returning thither from each of his repeated tours throughout the many scores of cities and villages which then existed in Galilee. Wherever he went the keynote of his preaching was the same as John's had been, "Repent, for the kingdom of heaven is at hand;" but as time passed his instructions, exhortations and warnings swept throughout the whole scale of human experience and touched every note of religious and moral truth. The keynote of his teaching about God was his love, infinite, untiring, eternal. On the ground of this love he proclaimed pardon to every penitent, even though a harlot or an outlaw. But this certainty and freeness of forgiveness was not allowed to diminish the loftiness and imperativeness of the standard of duty which he held up. Indeed, the high moral tone of his teaching, accompanied as it was by a constant and insistent demand for absolute sincerity, and his disregard for all mere forms, without the spirit in particular, his teaching and practice in reference to fasting, ceremonial purifications and Sabbath keeping, combined to set against him the Pharisees and through their influence the leaders and officials of the nation.

Popularity.—For a long time his popularity was great and throngs gathered to see and hear him, attracted in part by the reports of his miracles. Far and wide the stories were told that diseases yielded to his command, that the fevered, the palsied, the blind, the deaf and dumb, the lepers, the demonized, were restored to soundness, and, later, that on repeated occa-

JESUS CHRIST

sions he brought the dead to life. But these great works were distinctly secondary. He was first and foremost the Prophet of Nazareth, the Preacher. As such he spoke with peculiar attractiveness and power. His style was simple and direct, and his discourse was frequently adorned with unequaled parables, illustrations drawn from nature or common life, which, though sometimes veiling the truth from the thoughtless, sometimes added immensely to its clearness and effectiveness. His activity as a preacher at first won him steadily increasing popularity among the people at large, until, about two years after his work began, 5,000 men, whose hunger had been satisfied by his power on the lakeside, determined to make him king. But in this purpose they lacked all real sympathy with the character and aims which Jesus exemplified. The kingdom which centuries before the prophets of the nation had foretold was a kingdom to be sure, but a kingdom which should be based on a right relation of its subjects to God and existing only to serve the divine ends. The Jews as they read these prophecies had seen in them, only something political, worldly and selfish. Now when Jesus in fulfilment of prophecy had come to offer himself to the nation as its promised king, he would be king only as his kingdom might be the expression and instrument of a religious people, deeply, purely, unselfishly religious. So at the very climax of popular favor his clear vision instantly recognized how widely their ideals and purposes differed from his.

The Twelve Apostles.—For some time this condition of affairs had been anticipated, and Jesus had laid his plans and shaped his work accordingly. Since the Jewish people would have no such kingdom as he was about to establish, he had several months previously organized under the name of apostles a group of 12 of his disciples, to whom he would impart himself, and on whom he would so far as possible stamp himself, that they in turn might repeat his activity in their relations to others. Although he retained the name kingdom, what he looked forward to establishing was not a political but a spiritual community or body.

After the choice of the apostles the discourses of Jesus had been largely shaped for their special benefit: after his rejection of the offer of kingship from the unappreciative multitude, who in turn instantly deserted him when they saw that he would refuse to gratify their selfish hopes, his work was mainly for the benefit of the twelve, although he neglected no opportunity which came within his reach of trying to touch the soul of the nation or of individuals. Much of the last year of his life Jesus spent in seclusion. He made a journey, doubtless traveling in leisurely fashion, northwest from Capernaum to Sidon, returning as it appears by a roundabout route through the Decapolis, and another journey northeast to Cæsarea Philippi; some time was spent in Perea to the east of the Jordan; and though he seems more than once to have shown himself conspicuously in Jerusalem or its immediate neighborhood, yet during most of the time which he spent in Judea he secluded himself in an obscure village named Ephraim.

So far as the work of Jesus was concerned, the most significant event of the last year, if not of all the three years of his ministry, was the conversation with the apostles near Cæsarea

Philippi as to the opinion of him which generally prevailed and as to their own convictions. While Jesus is reported at least once to have claimed to be the expected Messiah, and while this claim was necessarily implied in much that he had said of himself, and while some of the twelve had very early expressed the opinion that they had found the one of whom Moses and the prophets had spoken, yet this view had never found expression as their matured conviction. Such expression Jesus at last sought. His first question was as to the common sentiment concerning him, and the frank answer was that while he was generally recognized as one far beyond the ordinary, he was not at all recognized as the Promised One. In face of this answer Jesus pressed the further question, "What am I to you?" and the answer of Peter, one speaking for all, was that he was the Christ. This answer assured the ultimate success of his mission, for these followers would win more. But he could not fail at the same time to foresee the irrepressible conflict between himself and the leaders of the nation, and so, relying on their faith in him as the Christ, he immediately began to familiarize them with the fact of his death, though this only confused and offended them, and at the same time to add promises of resurrection which they do not seem to have grasped at all.

The apparent failure of the mission of Jesus which he thus foretold, culminating as it did in his rejection and death, was due alike to what he was, what he taught and what he demanded. He himself was devoted with absolute single-mindedness to his work, sincere, unselfish, loving, beneficent, and pure with such perfect and manifest purity that only a few voices of detraction have ever been out of harmony with the else unanimous recognition and assertion of the sinlessness of his whole life. His teaching, while not in all respects original in matter or form, was in spirit and effectiveness such an advance on the Old Testament which he confirmed or the rabbis with whom he largely agreed that it seemed "a new teaching." He demanded of others the same perfection of sincerity, altruistic self-forgetfulness and supreme devotion to the will of God which he himself practised, and he as sternly denounced hypocrites as he tenderly welcomed penitents. All his teaching came with a unique tone of authority and this was made more significant by the claims which he advanced for himself. He occasionally asserted and constantly implied that he was a special messenger from God and unique representative of him, and from time to time he distinctly claimed divine attributes and powers. Thus he spoke; to confirm this he pointed to his miracles; as such he held himself up as the proper object of supreme and absolutely limitless devotion; the recognition of his supremacy he demanded of all and gladly accepted from his disciples, a self-assertion which in view of his sincerity and simplicity of soul is as significant as in view of his transparent honesty coupled with unsurpassed sensitiveness to evils is the absence of ever confessing a fault. Between such a one with such a message and such demands and the rulers of the nation at the time there was necessarily an irreconcilable antagonism which could end in no way but in his death.

JESUS CHRIST

The Messiah.—In the spring of the year 29 (possibly 30), after Jesus had been before the public for three years, the task of implanting the spiritual kingdom in the hearts of the select 12 was so far completed that it would be permanent, and at the same time the conflict with the authorities could not wisely be longer postponed. Accordingly Jesus went up to Jerusalem to the Passover with the throngs which assembled at that time from every part of the country. While he gave repeated proofs that in spirit he was walking in the shadow of the cross which he foresaw at the end of the road, yet this journey, unlike those which had preceded it, was intentionally made, by the sending of 70 messengers before him to proclaim his coming, a significant progress through the country. Reaching the neighborhood of Jerusalem, he stopped for the Sabbath at the neighboring village of Bethany, to which he returned each night till the end, and then on the following day he made a somewhat formal entry into the capital city. It needed only that he should mount a riding ass that those who accompanied him should be reminded of an ancient prophecy, and they, with another throng which came out from Jerusalem to meet him, acclaimed him as the promised and coming king, carpeting the road before him with green branches from the trees at the roadside and with their own clothes thrown before him in the zeal of their loyalty. Thus they led him to the Temple, where the procession dispersed. While informal and at first thought only a failure in its lack of definite result, this "triumphal entry" had deep significance as a public claim of his right to rule the nation as God's appointed representative, and he stopped short of assuming this office only because he desired and demanded first the acceptance of him by the nation. During the days that followed he repeated this claim in various ways; again he drove out of the Temple the huckstering crowds so out of harmony with its proper use, and in prolonged controversy with the representatives of all the parties of the time he bore himself as their Master and proved himself such. All this goaded his enemies at last to action, and through the treachery of Judas Iscariot, one of the inner circle of 12 disciples, almost at once an unlooked-for opportunity presented itself to them.

The Last Supper.—On Thursday evening of Passover week, after special precautions to keep secret the place of their assembling, Jesus sat down at a last supper with his apostles to what he knew would be his last interview with them before his death. While the traitor has gone out to secure his arrest, he pours out his soul to the others in words too tender and profound for their comprehension; he warns them that they will speedily desert him to go alone to his fate; he tells them something of the unique significance of his death in language which contains in germ the later doctrines of the Church, on this point; presenting them bread and wine, he instituted the second of the two rites of the universal church and finally commends them and all future believers in him to God in a prayer of incomparable elevation and pathos. He then went out to a resort familiar to him and his friends, an olive grove named Gethsemane in a valley close to the walls of the city. There

the horror of the coming hours, not craven fear of death, but distress at the very thought of the tremendous experience which he must undergo in soul, drew from him a thrice repeated prayer of such intensity that the very blood was forced through the pores of the skin, but on the prayer followed serenity of resignation and purpose which continued unruffled to the end. Then he awakened his disciples who to his disappointment had repeatedly been overcome by sleep and so had left him to his spiritual distress without even the sympathy of his friends, and went to meet the force of Roman soldiers and Temple guards which in needless precaution the officials guided by the traitor brought to seize him. He quietly submitted to arrest, and his followers struck but a single blow in his defense and then scattered in the darkness, two of them, however, John and Peter, following at a distance, the latter only to deny later all discipleship and even acquaintance.

Trial for Blasphemy.—While some details of the four accounts of the trials of Jesus are obscure, if not inconsistent, yet their general course may easily be made out. At the house of the high priest Caiaphas, or of the still more influential Annas, his father-in-law, and an ex-high priest, there was before daylight an informal session of all the Sanhedrin who could be gathered. Unable to find even perjured testimony which was sufficiently consistent to warrant his condemnation, the high priest as president of the great court of the nation put Jesus under oath, and asked him if he claimed to be the Christ. Firmly and positively Jesus answered that he was, whereupon his enemies without even pretense of investigation declared this claim to be blasphemy for which according to Jewish law he must die. But this verdict would be legal only if rendered in the daytime, and so, having been left during the interval to be the object of mockery by the guards, as soon as the day broke, he was formally arraigned and condemned. As, however, the right to inflict the death penalty had been reserved to himself by the Roman procurator, in order to accomplish their purpose they must secure his condemnation of Jesus in addition to their own, and accordingly the Sanhedrin conduct him to Pilate and demand his execution. But Pilate refused to order his execution without investigation, and when they charged him with instigating sedition against the Roman government, the judge instantly recognized their malicious insincerity and the innocence of the prisoner. In his consequent desire to release him Pilate in turn pronounced him innocent; sent him to Antipas, who only made sport of him and returned him: vainly tried to stir up the populace to demand his release according to the custom that a prisoner should be released at Passover time; ordered him scourged in hope that that cruelty would satisfy his enemies; displayed him bloody from the torturing lash and crowned by the soldiers with thorns in cruel jest, fancying that this sight would surely evoke pity; but finally, terrified at the mutterings of the crowd and fearing lest should he persevere charges might be made to the emperor against himself, Pilate ordered the crucifixion of Jesus.

The Crucifixion.—The execution took place at once, scarcely later than the middle of

JESUS CHRIST

the forenoon. Although so far weakened by the sufferings of the night and morning that the sufferer fainted under the cross which, as was customary, was laid on him to bear to the place of execution, he bore himself throughout with majestic patience and dignity. Under the jeers of his triumphant enemies, in sight of his mother and friends, in the unexplained and portentous darkness which beginning at noon lasted for hours, amid the indescribable physical tortures of the cross, he spoke but to pray forgivingly for those who were the agents of his suffering, and to commend his mother to John, her nephew and his most intimate and beloved disciple. At mid afternoon he uttered a cry to God, "Why hast thou forsaken me?" which can be understood only as expressive of intensest soul agony. As if this agony culminated and ended with the cry, he then spoke calmly of his thirst and took the drink which a sympathetic bystander pressed to his lips, then commanded his spirit to God, and with a loud shout expired, it would seem with a literally broken or ruptured heart. Although death seldom came so soon to the crucified, yet the fact is undeniable in the case of Jesus, for when somewhat later the criminals who had been crucified with him received a blow intended to hasten their death, the soldiers recognized that he was already dead, and yet one of them thrust a spear deep into his side, apparently touching the heart, and on Pilate's inquiry the officer in charge certified to his death. By leave of the governor two members of the Sanhedrin, who were secretly disciples, took down the body and hurriedly but reverently buried it at the close of day not far from Calvary, where he had been crucified, in a rockhewn tomb, which later was officially sealed.

Of the facts relating to Jesus during the next few weeks, no less than five (if the last verses of Mark are by another hand, then six) separate accounts are preserved, no two precisely agreeing, but, on the other hand no two being mutually contradictory, and one of these accounts, that of Paul, was written within 25 years of the events narrated. It is told that first women going at the dawn of Sunday entered the open tomb but found not the body of Jesus; that later Peter and John also found it empty; that Peter, then ten of the apostles together, and also two other men miles from Jerusalem, as well as Mary Magdalene, saw Jesus that same day in recognizable human form and talked with him; that these appearances and conversations were repeated at different places and in varying circumstances for about six weeks; that on one occasion he was seen by as many as 500 at the same time, some of whom were at first doubtful as to the facts; and that then these manifestations entirely ceased, except for the experience of Paul. It is certain that the disciples in these few weeks had come to be convinced that Jesus had actually been with them and that consequently they passed out of a state of gloom and despair into joyous and unflinching boldness; that the belief in the physical resurrection of Jesus was an essential part of the creed and preaching of the primitive church; and that the first day of the week became the Christian day of worship. No plausible explanation of these facts, of the empty tomb; of the reports and convictions of the

disciples; who claimed to have seen and talked with Jesus in human form, especially of the case of Paul; of the revulsion of feeling on their part; of the consequent foundation of the Christian Church, and of the consecration of the first day of the week, has ever been given except that after his death Jesus, in this as in so much else unlike all other men, entered by resurrection and later ascension upon a new course of life and a new course of activity. Without the resurrection as well as the life and death of Jesus historical Christianity could never have come into existence; by it he became the founder of the Church and the dominating personality of the ages.

DAVID FOSTER ESTES,
*Professor of New Testament Interpretation,
Hamilton Theological Seminary, Colgate University.*

Jesus Christ, Logia of, the sayings of Christ, a title given to certain first century papyri, discovered in the course of excavations at Oxyrhynchus carried on under the direction of Professors Grenfell and Hunt. The first find of these logia was made in 1897, but in 1903 a second collection was discovered. It has been suggested that these may be remains of the so-called Gospel of St. Thomas. Each of the recently unearthed sayings, like those of 1897, is introduced with the sentence 'Jesus saith.' These sayings are for the most part new, though one of them is in part known to have occurred in the Gospel according to the Hebrews. The new sayings are not so well preserved as the 1897 papyrus, in which the deep blackness of the ink was wonderful. In the later discovered papyri the ends of the lines are lost throughout, but there is this advantage: the introduction to the entire collection of sayings, of which both papyri are probably a part, is given, stating that these were the sayings in the logia which Jesus spoke through Thomas and perhaps another disciple.

The first saying is that one of which a part is already known to have occurred in the Gospel according to the Hebrews. It is one of the most remarkable sayings ascribed to Christ. It says: "Let not him that seeketh cease from his search until he find and when he finds he shall wonder; wondering he shall reach the kingdom and when he reaches the kingdom he shall have rest."

The kingdom of heaven is also the subject of the second saying, which is much the longest and most important. The kernel of it is that most remarkable and profoundly mystical saying recorded by St. Luke alone: "The Kingdom

JESUS COLLEGE—JETTIES

of God is within you," but the saying in the papyrus appears in quite different surroundings from those attributed to it by St. Luke and extends far into another region. When published the sayings will doubtless be widely discussed by the critics as the logia of 1897 were. They are of enormous interest on account of the variations they disclose from the accepted texts.

One variant which Prof. Hunt quotes as of great value is Luke xi., 52, which reads: "Woe unto you, lawyers; for ye have taken away the key of knowledge, ye entered not in yourselves, and them that were entering in ye hindered." The papyrus, however, reads: "Ye have hidden the key of knowledge, ye entered not in yourselves and to them that were entering in ye did not open."

The recently discovered papyrus contains part of the discourse of Christ closely related to certain passages in the Sermon on the Mount in St. Matthew and to the parallels thereof in St. Luke; and secondly, part of the conversation between Christ and his disciples. The latter presents a striking resemblance to the well known story recorded in the Gospel according to the Egyptians and in the uncanonical gospel used side by side with the canonical gospels by the author of the Second Epistle of Clement, which was written about the middle of the second century. It consists of an answer to the question put in the Gospel according to the Egyptians into the mouth of Salome; in the uncanonical gospel quoted by Clement into the mouth of some unnamed person, but by the recently discovered papyrus into the mouth of the disciples. The question, with some variations of form between the three, was: "When will Christ's kingdom be realized?" The answer as recorded in the Gospel according to the Egyptians was: "When ye shall trample on the garment of shame; when the two shall be one and the male as the female neither male nor female." The papyrus differs somewhat from this, and incidentally shows that the interpretation generally given to "When ye shall trample on the garment of shame" is incorrect. It is usually considered to signify "when ye put off the body; that is, to die." But the papyrus shows that the real point lies in a mystical allusion to Genesis iii., the phrase meaning, "When ye have returned to the state of innocence which existed before the fall."

Jesus College, Cambridge, England, founded by Alcock, bishop of Ely, in 1496. It has 16 foundation fellowships, open without restriction to all his majesty's subjects. Five were of the original foundation, and the others have been added by subsequent benefactors. Six of the fellows are required to be in orders. The mastership and one fellowship are in the absolute appointment of the bishop of Ely. To the other fellowships on a vacancy the master and fellows nominate two candidates, one of whom is elected by the bishop. There are numerous scholarships.

Jesus College, Oxford, England, founded by Queen Elizabeth in 1571 on the petition of Dr. Hugh Price, treasurer of St. David's, Wales, who left lands for the maintenance of a principal, eight fellows, and eight scholars. It was increased by different benefactors until it came to consist of a principal, 19 fellows, and 18 scholars; but by the ordinance of the university

commissioners the fellowships have been reduced to 13, a half of which as near as may be are to be filled up by natives of Wales, the other to be under no restriction by reason of birth. A fellowship founded by Charles I. for natives of Guernsey and Jersey has been converted into two scholarships for natives of these islands or persons educated at Elizabeth College, Guernsey, or Victoria College, Jersey. This was the first college founded on Protestant principles.

Jesus Island, Canada, an island in the Saint John River not far from where it joins the Saint Lawrence River; area, about 1,200 square miles.

Jet, a mineral, which is found in compact masses so hard and solid as to be susceptible of being turned on a lathe and manufactured into ornamental articles. It has been worked for centuries in Whitby, England. It is found in thin laminations, which subsequently thicken out to 2 or 3 inches in the upper lias strata in that neighborhood; a lower bed, from which the best quality is obtained, has a thickness of 20 feet, and is known as jet rock. Jet is supposed to have been worked in England as far back as the time of the Romans. Jet rosaries and crosses were common in the Abbey of Whitby when it was a resort of pilgrims. The jet manufactures of Whitby fell away about the time of Queen Elizabeth, and were revived in 1800. It is also manufactured at Scarborough, England.

Jetties are dikes at the mouth of a river or across a harbor bar to increase the riverine or tidal current by narrowing the channel, and thus scour out a deeper bed, to accommodate navigation. Single jetties are solely at the mouths of rivers with strong currents, to deflects these to one side of its natural channel, but in most rivers, and in all harbors they are double, forming an entire artificial channel. Briefly, the physical principles are: The power of water to transport solid matter varies as the square of its velocity, so that increasing the strength of current two fifths will about double its sand-carrying capacity; the velocity increases with increase of slope and decrease of friction; the slope is increased by narrowing the channel, since it forces flood waters inside or outside to rise higher at the entrance, and the friction decreases as the width of the channel; and lastly, if a channel of a given depth and width passes a given quantity of water, then a narrower channel involves either a permanently greater height of water if the bed were rigid, or the scouring of the bed to a depth which, multiplied by the new width, will produce an equal cross-section with the old. The increased slope and the correspondent velocity vanish as the water cuts a deeper basin; but the velocity due to lessened friction does not, nor do the deepened channel, the greater discharge through it, and the greater tidal fluctuation due to the larger basin. The channel is scoured along until the deepening sea establishes an equilibrium of action.

The system is not new. A number of important European rivers were jettied even before the middle of the last century, and others not much later. The Danube at Sulina had been deepened to 21 feet, from 8 feet before; and in 1874 Eads found seven German rivers, including the Oder and Vistula, improved so that with

JEUNE — JEVONS

initial channels of 4 to 7 feet, they then had 13 to 23.5. Several of these are still deeper now, the result increasing somewhat for many years under the same conditions. The Neva in Russia has also such works; as also the harbors of Calais and Dunkirk in France. In the United States a very great number have been constructed, both for rivers and harbors; the greatest of all are the jetties at the mouth of the Mississippi, and as the general principles are alike in all, these may be briefly described.

The Mississippi discharges its waters to the Gulf not by one channel, but in the main by three, running through "passes" 12 to 17 miles long from the delta land to the sea, and widely divergent. The largest is the Southwest Pass; next the easternmost, Pass à l'Outre, with two branches. In the middle is the smallest, South Pass, 600 to 800 feet wide, and taking not over a tenth the total discharge, with a shoal at its head only 15 feet deep, and a bar at its mouth only 8 feet; so that, with 30 feet of water through the delta, it was unserviceable for deep-water navigation. Capt. James B. Eads offered to build jetties to deepen the bar at Southwest Pass from its then 13 to 28 feet; but Congress preferred South Pass, as cheaper and simpler, needing work only at the head and foot. Work was begun in June 1875, and within nine months the water was 13 feet on the bar; by 1879 it was 29 feet; it is now over 30.

The west side of the pass had silted up into land 4,000 feet farther out than the east, so that the west side of the two parallel dikes built out to 30 feet depth in the Gulf was about 7,800 feet, while the east was 11,800. First piles were driven in two rows 1,000 feet apart (the piles 12 feet apart) to mark the lines of the projected jetty-walls. Then mattresses were built, of willow branches, or young willows 15 feet long, cut with the leaves on, laid in four courses, each crosswise to the next, and fastened together at top and bottom by pine planking $2\frac{1}{2}$ inches thick, dowelled with hickory pins; this compressed the willows to a thickness of about 2 feet, and their brush-ends projected 3 or 4 feet. These mattresses were 100 feet long; for the bottom course they were made 50 feet wide, but steadily narrowed for each of the four courses at first needed to bring them to the surface of the water, the top one being 20 feet wide. Wider ones were used in deep water. These were built on shore, on ways as for launching boats; towed by tugs to the places indicated by the line of piles, and sunk by loading one or two tons of stone on top. Once down, they speedily filled with sediment and became solid. At the sea ends foundations of mattresses 200 to 300 feet broad were laid. For two or three years these stone-laden mattresses gradually sank in the soft bottom, and new ones were added at the top to bring the surface even. The willows not imbedded in sediment were revetted with stone. Where exposed to storms, they were considerably sloped, and more thoroughly revetted. The sea ends were afterward capped with concrete blocks. The jetties have undergone considerable repairs since then, but have essentially done their work of making the river navigable for large vessels.

One of the difficulties was this: If obstacles were placed in the way of a free flow of water, the river would by so much at least desert this pass and run through the others; so that their

heads had to be closed up to a sufficient extent to prevent this. Plans for improving the Southwest Pass in like manner have been prepared by the government engineers, but have not been executed.

At the mouth of the Brazos, west of Galveston, Texas, an ingenious plan was adopted for avoiding interference in the work by flood-tides: A long trestle was built out to deep water above high tide, the mattresses hung under it by ropes, and the stone dropped on them from above to sink them. Instead of being launched from shore and towed, they were carried on a portable railway running on top of the trestle, and let down.

The Columbia River jetty is the most conspicuous example of the single instead of the double dike. It is $42\frac{1}{4}$ miles in length, the longest in the world. The bar at the mouth of the river, ever shifting and sometimes not over 12 feet deep, had half spoiled this superb river for navigation, and was greatly dreaded. But the river has a mean high-water discharge of 600,000 cubic feet per second, a mean tidal ebb of 1,000,000, with tides of 6.2 feet; and in 1884 a single curved line of brush mattresses with rubble-stone copings was begun, completed in 1894, to turn the current away from spreading itself on both sides and scour out the channel on one. This was finished in 1894; it has formed a permanent channel 30 feet deep, and made the river a highway of the heaviest ocean commerce, with lines to all Pacific lands.

Others are too numerous for more than brief mention. At Yaquina Bay, Oregon, 115 miles south of the Columbia—an estuary 20 miles long discharging into the sea through a narrow, tortuous, shifting channel, and over a sand-bar with 7 feet of water—parallel jetties about half a mile long, one of rubble-stone on a rock bed, one of brush and stone on a sand bed, have doubled the depth of water and made the channel calculable. At Galveston, the single jetty was a relative failure, it needing a double one to converge the tides; and in 1896 the government completed it, with sides of 35,000 and 25,000 feet, costing over \$8,000,000, and furnishing 27 feet of water between the island and the mainland. Other notable ones are at the mouth of St. John's River, Florida, beginning at the sides of the river-mouth and converging to 1,000 feet apart at the crest of the bar. Charleston's double one has sides of 15,000 feet each.

Jeune, LADY MARY STEWART-MACKENZIE, English writer on social topics. She is the wife of Sir Francis Jeune and has long been prominent in efforts to relieve the condition of the poor of London. A volume of essays selected from her contributions to periodicals has been published under the title 'Lesser Questions' (1894).

Jevons, William Stanley, English logician and economist: b. Liverpool 1 Sept. 1835; d. Bexhill, near Hastings, 13 Aug. 1882. He was graduated from University College, London. Having obtained an appointment in the Royal Mint, he went to New South Wales in 1854, but afterward returned to England, and in 1866 became professor of logic, philosophy and political economy in Owens College, Manchester, and this post he held until his resignation in 1876 in order to accept the chair of political economy in London University. He retired from this

JEW — JEWELRY

position in 1880 for the purpose of devoting his whole time to literary pursuits. His writings include: 'Pure Logic' (1864) and 'The Substitution of Similars' (1869), in which he sought to popularize symbolic logic through a modification of Boole's mathematical methods; 'Elementary Lessons in Logic' (1870); 'Theory of Political Economy' (1871); 'The Principles of Science' (1874); 'Money and the Mechanism of Exchange' (1875); 'Primer of Logic' (1876); 'Primer of Political Economy' (1878); 'Studies in Deductive Logic' (1880); and 'The State in Relation to Labour' (1882). Among works published posthumously are: 'Methods of Social Reform' (1883); 'Investigations in Currency and Finance' (1884); and 'Pure Logic' (1890). In a pamphlet on the 'Coal Question,' he presented a mass of evidence to show that England's progress would be checked by want of coal; in his work in political economy he attempted to put the chief definitions in the form of mathematical quantitative formulæ, and in this way did important work in revealing the nature and relations of economic facts; he also developed the theory of marginal utility. His 'Life and Letters' edited by his wife were published in 1886.

Jew, The Wandering, a poetical personage of popular traditions, who owes his existence to a story connected with the well-known scene in the history of Christ's passion. As Jesus was on the way to the place of execution, overcome with the weight of the cross, he wished to rest on a stone before the house of a Jew, whom the story calls Ahasuerus, who drove him away with curses. Jesus calmly replied, "Thou shalt wander on the earth till I return." The astonished Jew did not come to himself till the crowd had passed and the streets were empty. Driven by fear and remorse, he has since wandered, according to the command of the Lord, from place to place, and has never yet been able to find a grave. Shelley, Lewis, Croly, and Mrs. Norton in England, Schubart and Schlegel in Germany, and Sue in France, have turned this legend to account. Goethe has sketched Ahasuerus with great spirit and humor as a philosophic cobbler at Jerusalem who opposes Christ with a cold worldly logic which will not look above the things of earth.

Jew of Malta, The, a tragedy written by Marlowe (q.v.) about 1587, first acted 1592, and first published in 1633, edited by Heywood. Shakespeare was largely indebted to Marlowe's play for his 'Merchant of Venice.'

Jewel-weed, Touch-me-not, or Snap-weed, popular names for two plants, *Impatiens aurea* and *I. biflora*, of the natural order Geranaceæ, well known in damp shady places throughout the cooler parts of North America, where they form dense masses. They are characterized by sac-like pendulous yellow or orange, more or less spotted flowers, and by their sensitive seed pods which when mature burst with the slightest touch and throw the seeds to a considerable distance. Hence the second and third names above. The first name is probably a survival of their use as antidotes for so-called *Rhus* poisoning.

Jewell, joo'ēl, Marshall, American statesman: b. Winchester, N. H., 20 Oct. 1825; d. Hartford, Conn., 10 Feb. 1883. He learned the

tanning trade in his father's leather belting business; went West, where he was a telegraph operator for three years, and in 1850 returned and re-entered his father's business. In 1868 he was the unsuccessful Republican candidate for governor of Connecticut, but in 1869 he was elected, and re-elected in 1871. During his administration as governor the present militia system was adopted, and the erection of the new State House begun. In 1873 he was appointed United States minister to Russia, and was recalled to become postmaster-general in President Grant's cabinet in 1874. He resigned in 1876 on account of disagreement with the President's policy in the Whiskey Ring frauds. His work in the Post-office Department was very effective and led to the discovery of the Star Route scandal, and to the introduction of several reforms. In 1880 he was chairman of the Republican National Committee and managed the Garfield campaign.

Jew'ery, ornaments for personal adornment, usually made of gems and precious metals. At some remote period primitive man gradually migrated northward from the tropical belt in which he probably first came into existence, and as he felt the colder temperature inconvenient, especially at night, he found it advisable to invent some sort of covering or clothing, by means of which he could obtain warmth. What the first clothing was it is of course impossible to say, but it may be conjectured to have consisted of belts of grass or leaves knotted together either by their own stocks or by accessory vegetable fibres. When men became hunters, which they did not do until they had progressed far enough to have invented offensive weapons, they no doubt soon used dried skins for clothing. A rough tanning of such skins could have been managed by rubbing them with fat. Then came the difficulty of fastening them. Some savage tribes still wear cloaks which have only a hole cut for the head to go through, and this is likely enough to be a primitive type; then also they might have been tied up with strips of sinew, but at an early stage they were pinned together with a bone or large thorn. Here is the germ of the brooch. Numbers of such pins have been found in all places where the remains of primitive man exist, and they range from the simplest forms to quite ornamental ones. The heads of the carved specimens show a certain amount of progression, and are often decorated with engraved lines, dots, and circles. Ivory, wood, and bone are all commonly used, and in time, as metal workings became known, these carved pins are imitated in bronze or gold. From the Stone Age, through the Bronze Age, up to the Iron Age, in which we are still considered to be, pins and their derivatives, brooches and buckles, have been universally used, and it is an interesting study to endeavor to trace their utilitarian development as well as their artistic and technical beauties. Starting with the earliest metal pins, which are of bronze, it soon appears that the head or thickened end is treated ornamentally, hammered flat, and pierced. Into the pierced hole in the top of pins are often found wire rings coiled several times, or single rings, as in plenty of specimens found in Ireland. In other cases of Roman pins found in Britain, there are chains of which a few links

JEWELRY TRADE

only are left, and in one case at least a pin the head of which was threaded with a chain of several links, was found among the debris of one of the Swiss lake dwellings. The modern safety-pin is quite the same in all essential points as one which was found by Dr. Schliemann at Mycenæ, and the same form, with the arch more or less specialized in design, has been very largely used North and South, East and West. The Greeks made the arch short, and enlarged and ornamented the nose or hollow for the pin to rest in; the Romans made the arch big, and set it with beads of amber and bronze, and fretted it out in innumerable ways, curves, spirals, and all sorts of twists and turns which the fancy of the artist could devise. The Roman fibulæ are more usually made of bronze or silver, but the Greek are largely of gold, and of exquisite workmanship.

Among the Romans of about the Augustan age, cameos were largely used as pendants; coins also, richly set, were so used. Charlemagne, in the 8th century, wore a splendid reliquary as his necklace, which was sent to him by Haroun-al-Rashid. This was buried with him, and was found on his neck when the body was exhumed in 1169. The use of ornamental monograms in jewelry began during the 14th century. Diamonds used in jewelry before the beginning of the 17th century are always cut, either as "tables" or "roses," the "brilliant" not being then invented, and all colored stones were cut in the rounded form known as "ca-bochon."

A French jeweler, named Daniel Mignot, during the beginning of the 17th century, is supposed to have first set rows of jewels close together in consecutive order. This notion was, of course, very suitable for working the monograms then so prevalent, and it has been more or less used ever since. From the 16th century pearls were much in fashion, and pendants commonly have single pearls or groups of pearls dependent from them. Toward the end of the 17th century pendants are found made of gold only, but exquisitely pierced, chased, and engraved, and some specimens of Portuguese work are remarkable for delicacy of execution; these are sometimes set with very small diamonds. Sprays of leaves and flowers, and knots of ribbon, during the 17th century, are made in metal, and thickly set with crystals—paste or real jewels—particularly by Venetian, French, and Portuguese, followed at a safe distance by English workmen. The best of these are by Giles Légare, and in the 18th century his follower, Pierre Bourdon.

The jewelers of the beginning of the 18th century did not hesitate to mix gold and silver in their jewelry. Gold was commonly used for the settings of colored stones, and silver for diamonds. Summarized briefly: (1) Savage tribes have used for their ornaments natural objects easily worked. (2) The cultured nations of antiquity have generally made their finest pieces of personal ornament of gold. (3) During the period of the Renaissance gold and silver, colored precious stones, and vitreous enamels were very largely used. (4) During the 19th century the diamond particularly claimed the attention of jewelers. See DIAMOND; GEMS; PEARL, etc.

Jewelry Trade, The. The manufacture of jewelry in this country is one of the oldest industries of which there is tangible record, for to the native American Indian's love of personal adornment we trace the origin of jewelry in America. The Indian chiefs covered themselves with the best that the handiwork of their tribes could produce, and we are told that their wrists, ankles, heads, ears, and even noses, all bore tribute to their vanity and their love for adorning their persons with trinkets.

The history of the early Dutch settlers informs us that they brought with them such articles as they needed for their personal adornment in the new settlements; and in the English-speaking towns from the very foundation of the colonies no one's attire was considered complete without buckles, brooches, and rings made of the metals in vogue at that time. So the industry of gold and silver smithing was soon established, and in each of the three principal towns in the colonies there were numerous gold and silver smiths, whose principal products were medals and other trinkets for Indian chiefs, and snuff-boxes.

Another product of the early silversmiths much in evidence was elaborate boxes in which were enclosed the parchments conferring the freedom of the city upon distinguished guests. These boxes or receptacles were usually made of silver with a lining of gold, and frequently of gold studded with precious stones. After Andrew Hamilton defended the liberty of the press in New York in 1734 the corporation bestowed their citizenship upon him, enclosing the parchment conferring this in a very elaborate box; and later others were presented to Lafayette, Washington, and Scott. The making of ornamental insignia conferred upon distinguished men developed into an important feature of the goldsmith's work, and the craft received so many accessions to its ranks that in 1788, when the adoption of the Federal Constitution was celebrated in Philadelphia, 35 goldsmiths and jewelers turned out in the procession. More than 20 years before this the profusion of silverware, jewelry, and other evidences of wealth in a prominent New York residence, it is said, incited Townshend to introduce the historic bill known as the Stamp Act, the entering wedge by which the colonies were finally separated from the mother country. The colonies which had the richest inhabitants, and as a consequence those who spent most in personal adornment, were South Carolina, Virginia, Maryland, Pennsylvania, New York, and Massachusetts. The tools used in the earlier days were much like those used by workers in other metals at that time, except that they were smaller and better finished for finer work. The extreme tenuity and the lack of brittleness of gold and silver gave play to great ingenuity in varying ordinary patterns with fanciful designs, and the attaining of a polished or burnished surface made necessary a more tender treatment. In the earlier years of the century the frosting of gold and the satin finishing of silver were unknown arts, everything coming from the workshop with a glittering surface, most of the ornamental or decorative work being either crude enameling, applied work, or engraving. Later the precious metals were also used conjointly with other metals, wood, mother-of-pearl, glass, porcelain, pearls, and gems; but most of these attempts

JEWELRY TRADE

were ambitious efforts to realize the ideals formed from studying, in books and single engravings that from time to time found their way to this country, the illustrations of metal-work. However, nearly every one who engaged in the business at that time learned it thoroughly, in the old-fashioned way that embodied all branches of the trade, so that a hundred years ago it was impossible to draw a distinction between the occupation of jeweler and either goldsmith or silversmith, or between watchmaker and either clockmaker or maker of fine mathematical instruments — each of these branches involving the others. An artisan, though expert, rarely found sufficient work to employ all his time in any one department of his handiwork, and thus, from no matter of choice, but from compulsion, divided his time and skill between his own and kindred trades. The seller of these goods then was a workman rather than a dealer, and it was essential for him to have an intimate knowledge of all kinds of metal and fancy work. The more progressive of these artisans developed by degrees into manufacturers, beginning usually with one, two, or three articles in stock, such as spoons, forks, rings, and other small pieces; and later hollow silverware, tea-pots, etc.

Providence became early one of the centres of the trade; for the industry secured a footing in that city soon after the Revolution, when the manufacture of silverware was begun by Messrs. Sanders & Pitman and Cyril Dodge. In 1805 four establishments were located there. These belonged to Nehemiah Dodge, Ezekiel Burr, John C. Jenckes, and Pitman & Dorrance. Their products were chiefly silver spoons, gold beads, and finger-rings, and they employed in all about 30 men. Some of them soon branched out into cheap gold jewelry, silver and other alloys being largely used, with a very small fraction of gold, while large articles were plated by the hammering process. Breast-pins, ear-rings, sleeve-buttons, and key-rings, in addition to the articles mentioned, were among the early products at Providence. About the same time work was also begun at Attleboro, which town for many years held pre-eminence in the trade. In 1812 it was stated that there was then sufficient gold and silver ware manufactured to meet every demand in the United States. In Newark the business of manufacturing goods of this kind began early in the 19th century. The town was favorably situated for manufactures, and the men originally interested in the enterprise, Hinsdale & Taylor, combined industry with enterprise. Philadelphia was always very prominent as a manufacturing town, and a large trade, particularly with the South and West, sprang up there. Bailey & Company were one of the jewelry houses early established in that city, and the firm, under a different name, still exists. About 70 years ago Maiden Lane, of New York, became the great centre of the jewelry business in this country. With the improvements in manufacturing elsewhere, new ideas began to affect the trade. The fresh desire for novelties gave an impetus to the trade, and New York became the natural market for the introduction of every new product. In the New York 'Mercantile Register' of 1848-9, in the chapter devoted to manufacturers of silverware, watches, jewelry, etc., we find the advertisements of the following houses, in the order named: Ball, Tompkins & Black (late Marquand &

Company), 247 Broadway; Allcock & Allen, 341 Broadway; Gale & Hayden, 116 Fulton Street; Tiffany, Young & Ellis, 271 Broadway; Wood & Hughes, 142 Fulton Street; Samuel W. Benedict, 5 Wall Street; George C. Allen, 51 Wall Street; Squire & Brother, 92 Fulton Street and 182 Bowery; and others. Some of these houses have gone out of existence, one still retains its original firm name, and three are conducted under different firm names, which yet embody some part of the original title.

The great advance of American art is nowhere more pronounced than in the art metal-work of the gold and silver smiths, which has long since placed American products at the head of the art metal-work of the world. Because of this and our wider knowledge of articles into whose manufacture good taste enters as an important factor, it is not surprising that, relatively to the population, far more jewelry and silverware are demanded than formerly. The designers now employed by gold and silver smiths are men of liberal education, who can, if required, draw and model from life, and paint in oil or water-colors. Much work in ornamental gold and silver ware has been done in this country by such men within the past 50 years, notably in the way of loving-cups, vases, metallic designs, and presentation pieces. As conspicuous among these may be mentioned the gold medals, valued at \$1,000 and \$500, presented by the State of New York in 1858 to Dr. E. K. Kane and Commander H. S. Hartstein, the Arctic explorers; and the silver vase made in honor of William Cullen Bryant, now in the Metropolitan Museum of Art. The testimonials presented to Cyrus Field upon the completion of the Atlantic cable in 1866 include a gold medal struck for the occasion, a gold box, and many pieces of silverware. Other notable specimens are the silver services presented to the arbitrators of the Alabama claims in 1873; the silver centrepiece, "Liberty Enlightening the World," presented to August Bartholdi in 1886; the testimonial presented to William Ewart Gladstone in 1887; the loving-cup to Edwin Booth; and a great number of yachting trophies for international and other regattas. Many of these trophies annually made are of exceptional merit, and examples of art metal-work that cannot be duplicated or equaled in any other country.

The discovery of gold in California in 1848 and 1849 gave us a home supply of this metal, and gave employment to metallurgists and miners. The opening of the expositions in London and Paris revealed to us the forms of art and the increasing business of the manufacturing jewelers in this country, and made comparatively easy the acquirement of inventions in machinery and tools necessary to reduce the cost of products. Since 1860 all kinds of goods for which plating is employed have been largely prepared by electro-metallurgy, the centre of production being chiefly in Connecticut, there being also large plants at Newark, N. J., and Providence, R. I. This process is highly valuable, because it places within the reach of people of limited means attractive tableware and other articles of utility now deemed indispensable, which, if not as artistic and as highly finished as solid silverware, are serviceable, and in many instances possess exceptional merit. The production of silver-plated ware, although a great industry, has not retarded or encroached upon the demand for

JEWETT

solid silver; in fact, many instances of recent date would indicate that, with the present low valuation of silver bullion and the mechanical improvements that have further reduced the cost of production, solid silver is rapidly increasing in popular favor and making serious inroads upon the sale of all small articles still manufactured in plated ware.

The production of watches is another American industry closely related to the jewelry trade. They are manufactured in a number of States, notably Massachusetts, Illinois, and New Jersey; the making of the watch-cases forms a separate industry, which thrives especially in Brooklyn and Philadelphia. The highest grades of watches, such as complicated chronographs, calendar and stop watches, and very small watches for ladies, are still imported from Switzerland. Until about 1850 precious gems and articles of virtu of high order were seldom sold in the United States. New York or Philadelphia jewelers acted merely as agents to obtain for patrons some desired articles from a European house. But now the objects of art and other accessories of a modern jeweler's stock represent many thousands of dollars, and include opera-glasses, Sévres ware, fine pottery, ceramics, enamels, glass, objects in rock-crystal, clocks, bronzes, marbles, plaques, antiquities, curios, and many costly pieces of bric-à-brac and cabinet ornaments that appeal chiefly to collectors and connoisseurs of art. In diamonds and precious stones America is in the front rank of nations as consumer, and New York is the largest market for gems and precious stones in the world. The art of diamond cutting and polishing, although established here for a number of years, recently, through the changes made in the tariff regulations, received such an impetus as to attract many diamond cutters from Holland to this country; and if further revisions are made in the tariff, admitting diamonds in the rough free of duty, it is not unlikely that the industry, which for generations has centred in Amsterdam and Rotterdam, will be centred before many years in New York, Brooklyn, and other cities of the United States.

In the matter of statistics the earliest figures that we have as to the production of jewelry are that in 1812 \$100,000 worth was produced in Providence. But as late as 1860 the returns were small. The jewelers and watchmakers of Philadelphia produced in that year \$691,430 worth; the silverware men, \$516,000; makers of gold watch-cases and chains, \$1,714,800. In New York the production was: of gold chains and jewelry, \$2,497,761; gold watch-cases, \$337,600; silverware, \$1,250,605. Newark made \$1,341,000 worth of jewelry; Providence, \$2,251,382 of jewelry, and \$490,000 in silverware. In 1890 taking the total production by cities, Providence was still first, and then, in order, are New York, Newark, Philadelphia, Brooklyn, San Francisco, Cincinnati, Boston, and Chicago. The bulk of the gold and silver products of Providence, Newark, and other eastern manufacturing centers is sold in New York.

The figures for 1880-1900 are as follows:

	1880	1890	1900
Establishments.....	739	783	908
Capital.....	\$11,431,164	\$22,246,508	\$28,120,939
Employees.....	12,697	13,880	20,676
Wages.....	\$ 6,441,688	\$ 8,038,327	\$10,746,375
Value of product....	\$22,201,621	\$34,761,458	\$46,501,181

These statistics, however, do not indicate what has been accomplished from an artistic standpoint. American jewelry and silverware have steadily advanced in the quality and the character of products as much as the mere quantity. When the industry was in its infancy we looked to London and Paris for ideas, designs, and models. But we no longer accept the models and ideas of our French and English cousins in the designing of our jewelry and silverware. Dealers no longer import foreign jewelry and silverware into this country, because American products are fully equal, and in most cases superior, to those of other countries, in both correctness and originality of designs and workmanship.

The success of 'American jewelry abroad is evidenced by the victories over its European competitors of a leading New York firm at the Paris expositions of 1878 and 1889, and the appointment of the same house by royal letters as jewelers, gold and silver smiths to the courts of England, Russia, Austria, Belgium, Italy, Denmark, Greece, Spain, Portugal, Rumania, Egypt, and Persia.

In conclusion, what additional progress has been made, and shown at the World's Columbian Exposition, and at later American "fairs," is of too recent date to present in detail in this article. Much has been written and printed upon the art metal display of the gold and silver smiths, publications at home and abroad for many months dwelling with lavish and minute detail upon the many extraordinary features of the exhibit, which the London "Art Journal" summarizes in an elaborate review, October 1893, as follows: "Judging by the productions exhibited, one may well be in doubt whether our much-boasted European pre-eminence in these things is to last much longer, and whether, after all, we shall not in the near future be compelled to regard the firms of New York as at least our equals, if not superiors, in the production of high-class gold and silver work."

CHARLES L. TIFFANY,
Tiffany & Co., New York.

Jewett, joo'ët, Milo Parker, American educator: b. Saint Johnsbury, Vt., 27 April 1808; d. Milwaukee, Wis., 9 June 1882. He was graduated from Dartmouth College in 1828, from the Andover Theological Seminary in 1833, and was professor of rhetoric and political economy in Marietta College (Ohio) in 1833-8. Having become a Baptist, he resigned his professorship, in 1839-55 was principal of the Judson female institute established by him in Marion, Ala., and at the same time edited the 'Alabama Baptist.' He then established a young ladies' seminary at Poughkeepsie, N. Y., assisted Matthew Vassar (q.v.) in founding Vassar College, was its first president in 1862-4, and subsequently was active in educational and religious work at Milwaukee, Wis. Among his writings are a treatise on 'Baptism' (1840), and pamphlets on 'The Relations of Boards of Health and Intemperance' (1874) and 'The Model Academy' (1875).

Jewett, Sarah Orne, American novelist and writer of short stories: b. South Berwick, Maine, 3 Sept. 1849. She was educated at Berwick Academy and became a contributor to the 'Atlantic Monthly' in 1869, in which periodical the larger part of her work has appeared. Her usual theme is the New England character seen

JEWFISH—JEWISH CHARITIES

from its most attractive side, its gentler aspects given greater prominence, and its harsher ones not unduly emphasized. Her works include: 'Deephaven' (1877); 'Play Days' (1878); 'Old Friends and New' (1879); 'Country By-Ways' (1881); 'The Mate of the Daylight, and Friends Ashore' (1883); 'A Country Doctor,' a novel (1884); 'A Marsh Island,' a novel (1885); 'A White Heron and Other Stories' (1886); 'The Story of the Normans,' an historical work (1887); 'The King of Folly Island, and Other People' (1888); 'Betty Leicester' (1889); 'Strangers and Wayfarers' (1890); 'A Native of Winby, and Other Tales' (1893); 'The Life of Nancy' (1895); 'The Country of the Pointed Firs' (1896); 'The Queen's Twin and Other Stories' (1899); 'Betty Leicester's Christmas' (1899); etc. Her literary style possesses great charm.

Jewfish, a huge Californian game-fish (*Stereolepis gigas*) of the sea-bass family (*Serranidae*). It has a single dorsal fin, the soft part of which is shorter than the spinous portion, and is brown with black blotches and becomes much darker with age. Among the dense growths of kelp in moderately deep water along the coast of southern California the jewfish finds a congenial home. It haunts the neighborhood of islands and is especially abundant about Santa Catalina. Belonging to a family of game-fishes and reaching a weight of 300 to 500 pounds, it has long been a favorite object of sport for ambitious anglers. It is commonly taken on hand-lines baited with small fish, is exceedingly gamy, and brings a good price in the market.

Two other fishes of the same family but more closely related to the groupers are known as the Florida or black jewfish (*Garrupa nigra*) and the spotted jewfish (*Promicrops guttatus*). The former ranges from Florida to Brazil, and the latter widely through the warm parts of both Atlantic and Pacific oceans. The black jewfish is quite common about the coral reefs, in the caverns of which it lurks. Although not especially gamy, its enormous size and weight, sometimes reaching even 1,000 pounds, have induced a few anglers to essay its capture with rod and reel. It is easily distinguished from the Californian jewfish by its greater robustness, strong canine teeth, and rounded caudal fin. Consult Jordan and Evermann, 'American Food and Game Fishes' (1903); Holder, 'Big Game Fishes of the United States.'

Jewish Calendar. The Jews date their era from the Creation, which according to their tradition was 3760-1 years before the Christian era. The Jewish year is a lunar year and consists of twelve months, with an additional one for leap year. The months have alternately 29 and 30 days, the first and thirtieth days being called New-moon. Each cycle of 19 years has 7 leap years, the 3d, 6th, 8th, 11th, 14th, 17th, and 19th. The spring months are called Nisan (in which the Passover is celebrated), Iyar, Sivan; summer includes Tammuz, Ab, Elul; autumn Tishri, Heshvan, Kislev; and winter Tebeth, Shebat, Adar, with 2d Adar for leap year. The civil year began with the month of Nisan; the religious with Tishri. Rules for the computation of the calendar were issued, after various meth-

ods had been employed in earlier centuries, by Hillel II. (330-365). The date usually assigned by Jewish writers to the year when Hillel fixed the calendar is 670 of the Seleucidan era, or 4119 A.M., or 359 of the Christian era.

Jewish Charities. On 26 April 1655, the board of directors of the Dutch West India Company wrote to Governor Stuyvesant as follows: "After many consultations, we have decided and resolved upon a certain petition made by said Portuguese Jews, that they shall have permission to sell and to trade in New Netherland and to live and remain there, provided the poor among them shall not become a burden to the company, or to the community, but be supported by their own nation."

The records of the Department of Charities of the city of New York on 31 Dec. 1902 show that in a Jewish population approximating 600,000 in Greater New York, in the almshouse on Blackwell's Island there were 17 pauper Jews, of whom the majority were blind, idiotic or possessed of some peculiar defect which prevented admission to existing Jewish charitable institutions. These figures indicate how thoroughly the Jews of New York have assumed the responsibility imposed upon them over 250 years ago. The same is true of Jews throughout the United States. In our modern day, under more favorable conditions and auspices, the Jew has, to some extent, become non-sectarian in his philanthropies. Hospitals, as a rule, supported and endowed by Jews, throw open their doors to sufferers irrespective of creed, color or nationality. Other instances could be cited of charities not medical, organized along similar lines. The free employment bureau of the United Hebrew Charities of New York makes no distinction with its applicants. The Educational Alliance in the same city offers its clubs and classes to Jew and Gentile alike. Jewish agencies, giving material relief, or to use a better term, those which care for the needy in their own homes, in the main confine their work to beneficiaries of their faith, without, however, making any rigid distinction. On the other hand, the trend of Jewish charity has been in the direction of caring for the Jewish poor, solely through Jewish agencies, and without the intervention or co-operation of other sectarian or non-sectarian societies or institutions.

The problem of the Jewish charitable societies of the United States to-day is the problem of the care of the immigrant. As such, it passes beyond merely local lines. In some of its manifestations it is national in character and in a few it has an international significance. The fact that the large bulk of the needy Jews in the United States reside in New York is accidental, and concerns the Jews of Denver and San Francisco equally with those of the eastern seaboard cities. In so far the problem is a national one. Moreover, to deal intelligently with the question requires a knowledge of the immigrant's antecedents, the impelling motive which brought him to the United States, and an acquaintance with his previous environment. And here the international phase of the question comes in. Roughly speaking, it may be said that there are no American-born Jewish poor. Of the 10,924 families who applied for assistance to the United Hebrew Charities of New York during the year ending 30 Sept. 1903, 2 per cent

JEWISH CHARITIES

were born in the United States. And of these the majority of heads of families were of the first generation. Jewish dependents who have an ancestry in the United States of more than two generations are practically unknown.

In the year 1881 began that great wave of emigration from eastern Europe, the end of which is not yet. Driven by a relentless persecution, which endangered not only their homes but frequently their lives, thousands of Jews were compelled to flee from their homes to seek new residence on these shores. The Russo-Jewish committee which originally undertook the work of caring for these immigrants turned it over very shortly to the Hebrew Emigrant Aid Society, which came into existence in December 1881. In one year this society spent \$250,000, \$50,000 less than had been spent by the United Hebrew Charities of New York in the seven years of its existence. In the first and only annual report of the Emigrant Aid Society, its president outlined as tersely as possible the efforts that had been made to provide homes and occupations for the thousands of fleeing exiles who reached these shores during the momentous summer of 1882. In the month of July the committee spent for board and lodging alone over \$11,700.

With the gradual falling off in immigration, the Emigrant Aid Society went out of existence, and the care of the needy immigrant who remained in New York and who became impoverished after residence, reverted to the United Hebrew Charities. In 1885 immigration again began to grow heavier and continued to grow in such numbers that in the following five years over 120,000 immigrants arrived at Castle Garden. In 1890 the immigration reached the figures of 32,321, the largest number ever recorded up to that time. With all that had been done, the real work of the charities was but to begin. In 1891 the religious persecution of the Russian Jews reached a climax. In the year ending 30 September 62,574 immigrants arrived at New York, of whom nearly 40,000 arrived between June and September. The entire charitable effort of the New York Jewish community was for the time directed out of the ordinary channels and applied to this monumental question of caring for the arriving Russian Jews. The Baron de Hirsch Fund, instead of utilizing its income for its educational work, appropriated over \$67,000 to the United Hebrew Charities to assist in the work of the immigration bureau. Over \$175,000 was spent by the United Hebrew Charities during this year. In September of 1891 it became apparent that there would be no cessation to the immigration, and that much larger funds would be necessary to give anything like adequate assistance to the unfortunates who were arriving at the rate of 2,000 per week. The enthusiasm which was aroused at a banquet tendered to the late Jesse Seligman brought into existence the "Russian Transportation Fund," which added over \$90,000 to the revenues of the United Hebrew Charities and which was given by citizens of New York, irrespective of creed. Later in the year, a standing committee of the society, known as the Central Russian Refugees Committee, was organized and was made up of representatives of the Baron de Hirsch Fund, the Russian Transportation Fund, the United Hebrew Charities and the American Committee for Ameliorating

the Condition of the Russian Exiles. The last committee was organized to secure the co-operation of relief societies in other cities, in order that the various European societies who were assisting the persecuted Russians to emigrate should thoroughly understand the attitude of the New York organization. The year, October 1891 to September 1892, will ever be a memorable one in the history of Russian emigration and of Jewish philanthropy; 52,134 immigrants arrived at the Barge office in that time. The treasurer of the United Hebrew Charities paid out the enormous sum of \$321,311.05, of which \$145,200 was spent by the Russian Refugees Committee between February and September.

Since the year 1881, fully 600,000 Jewish immigrants have arrived at the port of New York alone. Of these the bulk comprise refugees from Russian and Rumanian persecution, Austrians and Galicians. They came from countries in which many of them lived under conditions of appalling poverty. The records of the immigration bureau show that from the standpoint of material wealth, these immigrants are below the average of immigrants from other European countries. Due to their previous condition, a goodly percentage is illiterate. On the other hand, the number of skilled artisans and craftsmen is so large as to be distinctly noticeable. From the standpoint of dependency, it will be of interest to study to what extent this large body of immigrants has added to the dependent and delinquent classes of the communities in the United States. The only figures that are at hand are those of New York, which are higher than would be found in other cities and towns for reasons that are obvious.

In December 1899 a study was made of 1,000 families who had originally applied to the United Hebrew Charities for assistance in October 1894. Of these 1,000 applicants it was found that 602 had not applied for assistance after December 1894. Of the balance, 67 families were dependent on the society to a greater or lesser extent in January 1899. More detailed investigation disclosed the fact that nearly all of these 67 applicants were made up of families where the wage-earner had died, leaving a widow with small children, or of respectable aged and infirm couples unable to be fully self-supporting, or of families in which the wage-earner had become incapacitated through illness. In other words, after five years over 93 per cent of the cases studied were independent of charitable interference. The marked feature in the care of the Jewish poor in the United States is the almost entire absence of the so-called pauper element. Even the 67 families above mentioned cannot be included in this category. Widowhood is the resultant of purely natural conditions, and when it afflicts the poor mother with a family, it frequently produces a condition of dependence which has in it no characteristics of demoralization.

If there is one cause more than another leading up to this condition, it is the absence of the drink evil among Jews. The instances in which drunkenness lies at the bottom of Jewish dependency are so infrequent that they may be ignored. Combined with the absence of this vice, there are other virtues engrained on the Jew for centuries, all of which tend to the preservation of his self-respect and his self-esteem. Among these are the love of home,

JEWISH CHARITIES

the inherent desire to preserve the purity of the family, and the remarkable eagerness which he shows for education and self-improvement.

From what has preceded, it will be comprehensible that the Jewish charities of the United States, having a special problem with which to deal, have instituted special methods for its solution. In the main, relief organizations have followed the organized methods of sister societies. In the past 25 years, new organizations of all kinds have sprung into existence to meet the demands made by the constantly increased immigration. To revert to New York, when the Central Russian Refugees Committee went out of existence in January 1893, the decrease in immigration no longer warranting its continuance, the active work of assisting the arriving immigrants devolved upon the United Hebrew Charities. The work of this society is typical of similar Jewish organizations throughout the United States. The report of the fiscal year ending 30 Sept. 1903, shows that 10,924 individuals and families applied for assistance. Of these, 6,260 had applied for the first time. Material relief was granted to 7,200; 1,802 were found not to require assistance of this kind, and 1,202 were refused assistance for some cause or other. The society conducts an employment bureau which is free to employer and employee, and during the last fiscal year found employment for 3,892 applicants. It grants relief in kind, including groceries, clothing, shoes, furniture, etc. The extent of the society's work in this direction will be gathered from the statement that 51,875 garments and pieces of furniture were distributed last year. The annual disbursements for material relief alone amount to over \$150,000 per annum. Ever since its organization 30 years ago, the society has endeavored to uphold the principles of organized charity. In some instances it has antedated the charity organization societies themselves; as in the giving of relief in amounts adequate to make the recipient independent of further intervention on the part of the relief-giving agency, and the establishment of a graded, carefully regulated and supervised system of pensions covering if necessary a long period of years. As a rule, these pensions are given only to families where the wage-earner has died, and where, unless such provision were made, no recourse would be left, except the breaking up of the family and the commitment of the children to orphanages and similar institutions. To obviate the necessity of such commitment, the United Hebrew Charities disburses annually over \$35,000 in pensions. In the history of the society there is no form of relief which shows such good returns for the investment made. Families so supported do not become pauperized, since the subsidy which is granted enables the surviving parent to devote her time to the proper rearing of her children so that they may become useful and intelligent citizens.

Along the lines of making families self-supporting the United Hebrew Charities frequently grants assistance, presumably as a loan, in amounts varying from \$50 to \$250. These loans are made in special cases where it is not possible to make the applicant self-supporting through the ordinary channels of employment, etc. A wage-earner who has been incapacitated through illness or injury and hence unable to follow any routine work, may still be estab-

lished in some small business venture and be able to support his family. Thousands of dollars have been spent by the United Hebrew Charities along these lines with the most gratifying results—not only have beneficiaries become independent of the society, but many of them have managed to repay the loans made to them. Of all the problems which confront the average charity organization, possibly the most perplexing is the one of the family in which the mother must be the wage-earner. The kindergarten and the day nursery have by no means solved the problem. They are at best but makeshifts in an attempt to solve a situation which has its root in economic and industrial conditions. Again, the factory removes the mother from her sphere of influence over her children, and opens up opportunity for the growth of incorrigibility and waywardness on the part of the latter. In the hope of partially overcoming this difficulty, the United Hebrew Charities has for some years conducted a work-room for unskilled women in which the latter are taught various needle industries, in the hope that they may eventually be sufficiently accomplished to work in their own homes, and in this fashion supplement the family income. The amount of such work that can be found is limited. More and more, daily, the factory is competing with home industry to the exclusion of the latter. A study made by the society in 1902 showed that work could be obtained for women to do at home in industries such as silk-belt making, men's and women's neckwear, garters and hose supporters, paper boxes, slip covers for the furniture trade, over-gaiters and leggings, dressing sacques, hats and caps, flowers and feathers, beaded purses and other beadwork, dress shields, incandescent light mantles, embroidery and art embroidery, passementerie work, bibs, knit goods, etc. In the society's work-room the effort has been made to teach such industries to unskilled women, so as to enable them to become at least partially self-supporting.

It is needless to state that in a system as comprehensive as the United Hebrew Charities desires to be, provision has been made to alleviate distress in all its forms. Under the plan of dividing the city into districts, immediate relief can be given to emergency cases. These districts are in charge of co-operating societies known as Sisterhoods, who are responsible for the condition of the poor who have been placed in their care. Each of these agencies is practically a miniature United Hebrew Charities. Not only have they organized centres for the distribution of material relief, but along the lines of a more progressive philanthropy, the sisterhoods have developed day nurseries, kindergartens, clubs and classes of various kinds, employment bureaus, mothers' meetings, and in fact have become a social centre for the poor of their neighborhoods. Since a large percentage of the distress which is met with is occasioned by illness, medical relief of all kinds has been organized. Each district as a rule has its physician and its nurse, and where these are not at hand, co-operation has been effected with other organizations specially equipped for such work.

In very recent years, the spread of tuberculosis among Jews has merited the earnest attention of the society, and among its other activities it has been a pioneer in developing a

JEWISH CHARITIES

systematic plan for caring for such tuberculous applicants in their own homes, for whom no provision could be made in existing sanatoria. The campaign thus begun has been not only a charitable, but a social one. Not only have these unfortunates been given food, nourishment and medical care to aid them toward recovery, but in addition thereto, instruction has been given them in the rudiments of sanitation, and in the prevention of infection. It is significant that the work of the United Hebrew Charities in this field has been followed to some extent by the recently organized Committee on Tuberculosis of the Charity Organization Society.

The name "United Hebrew Charities" as applied to the New York organization is somewhat of a misnomer, since it does not include all Jewish charitable agencies in the city of New York. It would be more proper to speak of it as the consolidation of all the purely relief societies which existed in New York prior to 1874. Aside from these, there are to-day hospitals, orphanages, technical schools for boys and girls, trade schools, day nurseries and kindergartens, guilds for crippled children, burial societies, loan societies, societies for maternity relief, and a goodly number of smaller organizations which have been founded by the immigrants of the last twenty years. Among the most important large organizations and institutions in New York may be mentioned: The Mount Sinai Hospital, Lebanon Hospital, Beth Israel Hospital, Montefiore Home, Hebrew Orphan Asylum, Hebrew Sheltering Guardian Society, Hebrew Infant Asylum, and Hebrew Free Loan Association. It is estimated that there are over 1,000 Jewish organizations and societies in the city of New York to-day, whose activities to a greater or lesser extent are directed along philanthropic lines. Practically all of the larger organizations, such as the hospitals, etc., work in co-operation with the United Hebrew Charities. In some of the other cities in the United States, where the question of the care of the poor is not so complex as in New York, closer co-operation has gone by leaps and bounds. In cities like Philadelphia, Cincinnati, Chicago, Cleveland, and others, the individual societies have formed federations of charities, the purpose of the federation being to express the philanthropic impulse of the community in terms of greatest economy, the smallest amount of friction and the highest possible efficiency. In Philadelphia the federation is the common treasury. It acts as the common collection agency of all moneys and distributes them pro-rata among the various societies and institutions whose autonomy is not impaired by this method. In other cities, this plan with some slight variations is in force. In New York sporadic attempts to form a federation have been unsuccessful owing to the immensity of the problem. There are indications at present that federation may become a possibility in the near future.

In addition to these local federations, the various societies throughout the United States have joined together to form a national body known as the National Conference of Jewish Charities. At present it comprises the relief organizations of 53 cities. Two biennial conferences have been held and the third will be held in the city of New York in May 1904. The published reports of these meetings indicate con-

clusively the wisdom and the necessity of founding such a national organization. The rules governing the transportation of dependents which have been in force in the National Conference of Jewish Charities since its inception were adopted with alterations and additions at the last meeting of the National Conference of Charities and Correction at its meeting in Atlanta in May 1903. At the meeting of the National Conference of Jewish Charities held in Detroit in May of the same year, the writer introduced a resolution advocating the establishment of a central bureau for the placing out and boarding out of dependent Jewish children in private homes. At that time the work of devising such a plan was delegated to the Independent Order B'nai B'rith, a fraternal Jewish order, which at present has the entire subject under discussion, and has drafted a plan which has been submitted to the various Jewish societies and institutions throughout the country. In New York city, under local auspices a similar movement has been inaugurated. Since July 1903, at which time work was begun, applications have been received for children from 84 Jewish families. Sixteen children have been placed in boarding homes and four in free homes.

Some idea of the extent to which Jewish charities have been developed in the United States may be gathered from the following: In practically every city and town there are benevolent societies which look after the interests of the poor in their midst. Jewish orphan asylums are established in the cities of Atlanta, Baltimore, Boston, Brooklyn, Chicago, Cincinnati, Cleveland, Newark, New Orleans, New York, Philadelphia, Pittsburg, Rochester, and San Francisco. In New York there are three institutions and in Philadelphia there are two. New York has four Jewish hospitals and Philadelphia has two. Baltimore, Chicago, Cincinnati, Denver, New Orleans, and San Francisco have each one. Homes for the aged and infirm are found in most of the large cities. Similarly, educational movements along philanthropic lines are developing throughout the country. These include organizations such as the Hebrew Educational Society of Brooklyn, the Hebrew Education Society of Philadelphia, the Jewish Training School of Chicago, the Hebrew Free and Industrial School Society of Saint Louis, the Hebrew Industrial School of Boston, the Clara de Hirsch Home for Working Girls, the Hebrew Technical School for Girls, the Hebrew Technical Institute and the Baron de Hirsch Trade School, the last four being situated in the city of New York. The Maxwell Street Settlement of Chicago and the Neighborhood House in Saint Paul are under Jewish auspices. Cincinnati, Milwaukee, and Cleveland have Jewish settlements. In New York the Educational Alliance, the largest institution of its kind in the United States, has within the past few years developed a settlement with resident workers. Along educational lines, the Jewish Chautauqua Society, a national organization, has for the past two years conducted a summer school in philanthropy in connection with its summer assembly held in Atlantic City, N. J. At these sessions, important communal problems of interest to Jewish workers in philanthropy have been considered.

Other national organizations of importance are the Jewish Agriculturalists' Aid Society, the

JEWISH CHAUTAUQUA — JEWISH FRATERNITIES

Baron de Hirsch Fund, and the Jewish Agricultural and Industrial Aid Society. The first named, with headquarters in Chicago, is engaged in placing farmers throughout the Northwest, particularly in Dakota. The work of this society while not on an extended scale, has nevertheless given results and has demonstrated the fact that it is possible to take residents of congested centres, remove them to country districts, and make farmers of them. The Baron de Hirsch Fund was established under a foundation of the late Baron de Hirsch, the deed of trust being incorporated in March 1890. Its activities at present are directed to the conduct of the Baron de Hirsch Trade School in New York city and the Agricultural Colony at Woodbine, N. J., where the Fund has an Agricultural and Industrial School. The Fund likewise gives money to co-operating societies in various cities for the purpose of granting tools and teaching trades to recently arrived immigrants. The Jewish Agricultural and Industrial Aid Society is an off-shoot of the Baron de Hirsch Fund, receiving money from the latter society and from the Jewish Colonization Society, which was created under a de Hirsch endowment. Its purpose is to find agricultural and industrial positions for Jewish immigrants. Under the care of this organization are the various colonies in south Jersey, aside from Woodbine, and the organization has made farm loans to farmers in various parts of the United States, particularly in Connecticut. Probably the most important phase of this organization's work is the attempt to remove residents of the congested centres of large cities to places throughout the United States, where work has previously been found for them. In the first year the organization sent away 1,800 persons. In the second year 3,200 persons. During its present fiscal year, beginning 1 Jan. 1903, it has sent out 5,190 individuals, and its work is constantly increasing. The plan of the society is to find industrial positions anywhere in the United States, and having found them, to obtain individuals able to fill them from New York and other large cities like Philadelphia, Chicago, and Boston. In order to carry on the work as effectively as possible, the society cooperates with the Independent Order B'nai B'rith, which has lodges distributed throughout many of the smaller towns and communities in the United States, and with the benevolent organizations and societies represented in the National Conference of Jewish Charities. It has an office in New York city known as the Industrial Removal office, which is the centre of the activities of the society. From here all applicants who desire to leave the city are sent away, provided with the necessary transportation and with the guarantee that provision will be made for them at their destination until such time as they become full-fledged wage-earners. Should conditions require it, it is not uncommon for the society to send the wage-earner in advance and to make provision for the care of the family remaining here through the United Hebrew Charities. As soon as the society hears from its correspondent that the wage-earner is in a position to care for his family the latter is sent on and a reunion of the family accomplished.

On the literary side of Jewish philanthropy, it is interesting to note that the United Hebrew Charities of New York city is publishing a monthly magazine, 'Jewish Charity,' which is

devoted to the consideration of all topics of interest to workers in Jewish philanthropic fields.

LEE K. FRANKEL,
United Hebrew Charities, New York City.

Jewish Chautauqua, founded in 1893 by Rev. Dr. Henry Berkowitz of Philadelphia, and incorporated in 1899, with a body of officers representing the chief cities in the United States. This society has about 3,000 members, divided into various sections. Its courses include preparatory, two years, with readings in Jewish history and literature; Bible, four years; and special courses in post Biblical history and literature, 'Jewish Characters in English Fiction,' 'Beginners and Advanced Hebrew.' Its chief work of late years has been embodied in its summer assembly, at Atlantic City, N. J., which is held annually in July and lasts three weeks. It includes a summer school, popular lectures and conferences, literary and social entertainments, in which many prominent speakers participate. During the session of 1903 the condition of religious schools, dependent and delinquent children, how to relieve congestion in large cities, the status of the Jews of Russia, the attitude of Jewish university students toward Jewish problems, were the topics discussed. The average attendance at the morning sessions was from 150 to 350 persons and at the evening from 300 to 800 persons. During the summer of 1903 an English organization on the plan of the Jewish Chautauqua was formed at Ramsgate.

Jewish Exchequer, a special division of the Court of Exchequer of England (1200-90) which dealt with lawsuits between Jew and Christian, chiefly in reference to debts due the former, and recorded the taxes imposed on the Jews. The fact that it was found necessary to have a centre for Jewish business indicates the prominence in trade and finance of the Jews in England from the reign of Henry II. to the period of their expulsion (1290). The court did not long survive their departure. Many important data from its records have been jointly published by the Selden Society and the Jewish Historical Society of England.

Jewish Fraternities. While societies for mutual benefit exist in large numbers among the Jews in every land, in the United States, the fraternities or orders have acquired special popularity, and promote not alone Jewish solidarity but aid in maintaining many charitable institutions. These organizations as a class give pecuniary benefits in case of illness, and death-endowments, which latter insurance feature is now being made optional. The oldest and most influential is the Order of Benai Berith ("Sons of the Covenant"), formed 60 years ago, and having a membership of 30,000. Its 315 lodges extend over the entire country, and it has 13 lodges in Algeria, Bulgaria, Egypt, Turkey, and Palestine, 42 in Germany, 16 in Rumania, and 10 in Austria. It supports orphan asylums in Cleveland, Ohio, Atlanta, Ga., San Francisco, Cal., a home for the aged at Yonkers, N. Y., a free library in New York, while it co-operates with an orphan home in New Orleans, a technical school in Philadelphia, and a hospital for consumptives in Denver, Colo. The next leading order is the Free Sons of Israel, founded in 1849, with 103 lodges and 11,000 members. The Free Sons of Benjamin (1879) has 192 lodges; 14,088 male and 1,361

JEWISH SECTS

female members. The Berith Abraham (1859) has 288 lodges and 42,000 members. The I. O. Berith Abraham, with 302 lodges and 56,949 members, was founded in 1887. The Ahavas Israel Order (1890) counts 124 lodges. In addition there are seven other fraternities which have been recently started. The Order of Kesher Shel Barzel, founded a home for the aged at Cleve-land. Special efforts are now being made by the Benai Berith to institute lodges among the Russian and Rumanian immigrants, and the project of establishing a Jewish University of the highest rank has been brought to its attention.

A. S. ISAACS,

Prof. German Literature, New York University.

Jewish Sects. To the fact that Judaism has never been a sluggish stream, but was ever in active movement, we owe the existence of sects among the Jews. The right of liberty of thought was always exercised, and to the conflict of opinion the survival of Judaism is largely due. Apart from the individualism which is a marked element in Jewish character, the influence of surroundings has had a formative effect, and the rise of sects in the nations among which he lived accustomed the Israelite to the spectacle of sects in his own community, due usually to the interpretation of text or ceremony, or to the initiative of some resolute leader. The history of Jewish sects displays the same bitterness and hostility that characterize sectarian feuds in general, although since the dispersion there has been more rattle than fang in the conflict between schools and parties in Jewry. The synagogue has never proclaimed any dogma of infallibility, and the rabbi was never regarded as absolute authority over conscience and soul. Climate, temperament, and environment were often the determining factors in precipitating the conflict which was waged, not by fierce encounters on the bloody field, but by debate in the schools and in polemical treatises that aroused partisan outcry and led to peaceful secession within the fold. Judaism and the law were never at stake—it was only the interpretation of one body of teachers or individual opinion which had to shift its ground.

Samaritans.—A brief summary of Jewish sects may best begin with the oldest of all. The Samaritans, termed in the Talmud (q.v.) "Cuthim," are traced to the mixed multitude who were made to settle in Samaria on the fall of the kingdom of Israel. The religion of the new colonists was a blending of Mosaism and heathenism, which led to a gradual separation from the Jewish body. They took no part in the revived commonwealth under Ezra and Nehemiah, but formed their own community, with their own temple, which was destroyed about 120 B.C. by John Hyrcanus I. (q.v.). The Samaritans gradually lost whatever prestige they had claimed. They now exist as a small sect, with constantly dwindling numbers, at Nablus (the Arabic form of Neapolis, the name given to Shechem under Vespasian). Here perhaps 100 survivors follow their traditional rites, and sacrifice as of old on Gerizim. The Samaritans now possess interest only from an archaeological point of view, although their ritual and literature have value for students of the Bible and of post-Biblical history.

Pharisees.—This party, often misunderstood and maligned, and which has had the ill-fortune

(similar to that of the Jesuits, for example), of supplying the term "pharisaic," in the sense of hypocritical, was the great popular party in Judea, including the representative leaders and men of learning in the Asmonæan era, who strove to maintain the traditional faith and ceremonies at all hazards and despite political entanglements. It is the opinion of Graetz, the best-known Jewish historian, that, deriving their name from *Perushim*, "the explainers" (of Scripture), they formed the learned body of the nation, and can only be called a party by way of distinction from the Sadducees and the Essenes. The Pharisees were the religious enthusiasts of their day, loyal to every traditional observance, naturally with the defects of their virtues when such rigid adherence became formalism. But it is faulty generalization to stigmatize all Pharisees as hypocrites because some were insincere, as occurs in the history of every creed.

Sadducees.—This sect, probably named from one of their leaders, Sadok, constituted the party of wealth and political power, who made the law subordinate to the exigencies of the national life, and to whom the traditions of their religion were secondary when the independence of the nation was to be upheld. Hence the differences in interpretation of the law, which led to violent feuds and internece conflict at a critical era when union might have checked the advancing Roman legions.

Essenes.—Sprung from the Assideans of the early Maccabæan days, resembling in some respects the Nazarites, the Essenes were rigid separatists from contamination, large numbers of whom were ascetics, favoring celibacy and forming a kind of religious brotherhood whose relation to early Christian practices, like baptism, is a suggestive topic for study. They were mystics, too, the logical forerunners of the sect of Chasidim, which was to acquire more notoriety than good repute in later centuries. The Essenes exercised no political influence. It was reserved for the Pharisee and the Sadducee to employ intrigue, hatred, and bloodshed against each other until Jerusalem fell.

Karaïtes.—About the middle of the 8th century this important sect arose among the Jews in Moslem lands. Their name means "readers," and they were followers of the Old Testament, but not the Talmud or rabbinical interpretations. Just as a sect in Islam rejected the traditional ruling, so almost contemporaneously a sect in Jewry abandoned rabbinical tradition. The leader in the movement was Anan ben David, a native of Babylon, who, chagrined at his failure to become an ecclesiastical dignitary, resolved to organize a revolt against tradition. For a time the movement made headway, but it never gained many adherents, and to-day exists in remnants only in Jerusalem and parts of Turkey, in Egypt, Galicia, and the Crimea. The Karaïtes, however, contributed largely to the study of the Old Testament, for the conflict between the Talmudists and their opponents led to closer and more accurate inquiry, and Scriptural investigation was followed with scientific thoroughness. The Karaïtes were keen disputants, and their polemical onslaughts on the Talmudists furnish a piquant phase in the history of Jewish thought. They failed, however, in their protest, and no reformation resulted. It is of interest to note that to-day in Russia the Karaïtes receive special consideration from the government, and

JEWISH WOMEN'S COUNCIL

apparently are not subjected to all the harsh exactions under which the rabbinical Jews suffer. Their very limited numbers, however, may account for the toleration.

Sabbatians.—In the 17th century a remarkable sect arose among the Jews, the followers of Sabbathai Zebi (1626-76), who was born in Smyrna, went to Jerusalem in 1664, and there proclaimed himself the Messiah and predicted his approaching rule over the universe, with his headquarters in Jerusalem, restored and made glorious. The news spread rapidly and produced profound excitement in Turkey and elsewhere. It was a century of gloom and anxiety for the Israelite, the era of Jewish massacres in the Ukraine, and with the greater avidity he turned to hopes of a revived nationality; many in sober European lands began to prepare for the journey eastward. Such Zionist dreams are of frequent recurrence, and numerous have been the false Messiahs in Jewish history. Sabbathai's career, however, was to receive a sudden check: the Sultan of Turkey, Mahomet IV., disliking popular excitement, imprisoned the prophet when he visited Constantinople, and after two months' confinement his pretensions faded away. He made a tame confession of his dishonesty and became a convert to Islam when the Sultan suggested the step. Many of his adherents in Turkey, Poland, Italy, Austria, Holland, and Germany were not discouraged by his conversion, but still believed in his Messiahship. In 1668 on the Passover he declared that he had received revelations from the Holy Ghost and was permitted by the Turks to preach in the synagogues. A sect of Sabbatians was gradually formed, with special doctrines and rites of their own, gradually dissolving into minor bodies of no influence. The Sabbatians in Turkey adopted Islam in 1687, with Sabbathai's successor, his brother-in-law Jacob Querido, at their head. On his death, his son became their Messiah (1695-1740). This Jewish-Turkish sect still exists and numbers about 4,000 adherents. Sabbathai's followers in Poland fell into crass mysticism, with harmful influences on Jewish development. In Italy they soon ran their course, and in Holland and Germany they were unmasked and sought flight.

Frankists.—These were a sect named after their founder, Jacob Leibovitz Frank, born in Podolia about 1726, died at Offenbach 1791, who was one of the apostles of Sabbathai Zebi. His vagaries were as pronounced as those of his master. Ultimately, after heated disputes with the rabbinical Jews, he abolished the law, and his sect became Catholic and was absorbed by the dominant religion in Poland.

The Chasidim.—The people who bear this name, meaning "the pious ones," constitute a sect dating from about the middle of the 18th century, and which exercised a profound influence on the Jews of eastern Europe. In its inception, as Dr. Schechter states in his "Studies in Judaism," it was a revolt against the excessive casuistry of the contemporary rabbis and "a protest of an emotional but uneducated people against a one-sided expression of Judaism" without feeling and affection. It was to develop rapidly into mysticism, the reveries and revelries of the Cabala, which produced incalculable evil wherever it spread. Its founder was Israel Miedzibocz (1698-1759), later called

Israel Baal Schem, shortened into Bescht, born in a small village in Bukowina, and about whose childhood and youth wondrous legends are narrated. He became a rabbi in Podolia and Wallachia, teaching his doctrines to eager disciples and working miracles. In some respects he was an Essene of the 18th century, and he has been both condemned and admired. A religious revivalist, he drew much of his inspiration from the 'Sohar,' aptly called the Bible of the Cabalists, a clever literary forgery of the 13th century; but his idealism became a downward development in the sect's subsequent history. Under his successor, Beer of Mizrach, Chasidism extended to a more learned circle, who in their turn exercised a wider influence which led to many divisions and degeneracy. They were fiercely opposed by the rabbinical Jews. In Wilna their writings were publicly burnt (1772), and they were put under the ban. Solomon Maimon in his autobiography gives an account of this sect. It is still in full swing in eastern Europe, an aberration that will pass away with the spread of modern culture.

Other Sects.—The Falashas of Abyssinia, the Daggatouns of the Sahara, the Black Jews of India and Cochin-China, may be regarded as sects or colonies, along with the few remaining Jews in Kai-Fung-Fu, Province of Honan, China, and are mentioned to show the variety of type in present-day Israel. The divisions into "orthodox," "conservative" and "reform" Jews are largely arbitrary, and await more exact classification.

A. S. ISAACS,
Prof. German Literature, New York University.

Jewish Women's Council. Founded September 1893, this organization has been of marked value in awakening the interest of American Jewesses in the history and literature of their special creed as well as in developing among them modern methods in educational and charitable. Affiliating with the National Council of Women it has arrayed on a common platform its representatives. The latest survey of its condition and workings was given at its third triennial in Baltimore, Md., 2-11 Dec. 1902. There were present 3 officers, 7 directors and 52 delegates from 26 sections, with 2 delegates from Junior sections. Addresses were made by Miss Jane Addams, of Hull House, Chicago, on "The New Social Spirit"; other topics discussed were: "Aspects of Judaism in Cities and Small Towns," "Federated Charities," "The Juvenile Court." The Council consists of 64 active sections, with about 8,000 members, and 16 junior sections, with about 500 members. There are 82 study circles, 2,000 members, studying Jewish history and literature, and 12 circles studying methods in philanthropy. It has 18 religious schools among the poor, with 19 paid and 141 volunteer teachers, reaching 2,500 pupils. Thirty-three sections carry on activities in philanthropy, with settlements, sewing and industrial schools, five kindergartens, one manual training school, two gymnasiums, two free baths, two day nurseries, four personal service groups, two kitchen gardens, and other forms of useful activity, often open to all creeds. Cooperation is encouraged with the State Federation of Women, International Congress of Women, the National Jewish Hospital for Consumptives at Denver, Colo.,

JEWS AND JUDAISM

the National Needlework Guild and the Consumers' League. Mrs. Hannah G. Solomon, of Chicago, is president of the organization (1902-5).

Jews and Judaism, the religion of the Jewish people—whether called Jews, Israelites, or Hebrews—based upon the Old Testament, and developed in their ages of alternate wandering and settlement in various lands. Judaism presents a series of changes from age to age, and is inseparable from the history of the Jewish race. The story of Judaism is the story of the Jew. From its rude beginnings in the era of Abraham the Patriarch, down through the centuries of Bible environment; from the formation of a kingdom to the final destruction of Jerusalem by the Romans; from the period of dispersion East and West to the dawn of the Middle Ages; then through successive social and political upheavals to the birth of modern times and the gradual shifting of nations and ideas until the present day;—through all these vicissitudes Judaism has ever been moving, influenced by every current and new condition. In the days of Abraham it was ethical Monotheism; in the era of Moses, Mosaism; in later ages, when it was likely to degenerate, Prophetism arose to inspire new life. When the national existence was reaching its end Talmudism was its protecting garment, to continue as Rabbinism for a long period, and it is still vital in many lands. Then with Moses Mendelsohn (q.v.) and the French Republic, modern Judaism began a new era, which was to develop still further with the spread of individualism in life and thought, under whatever names, conservative or reform, it was known. To realize what Judaism is, it must be studied in its broader range as well as in close detail. It must not be limited to one period, and it must not be made co-extensive merely with its Biblical or post-Biblical epoch. Judaism awaits its historians, and their task is one that demands not only the exact knowledge of the origin, growth, and development of Jewish tradition, customs, rites, and laws, but also a comprehensive survey of the civilizations with which the Jew came into contact, and to which he gave and from which he received so much. Judaism may be only on the threshold of its influence, for at no period since its beginning has it been more diffused and universalized through the planting of the Jew in every land on the globe.

Ancient Jewish History.—The early history of the Jews is identified with that of Palestine, as told in the Old Testament. The narrative proper begins with Abraham and the Patriarchs, and continues through the story of Joseph in Egypt, to which Israel and his family remove, and the years of oppression under the Pharaohs. Then Moses appears as a deliverer, the revelation on Mt. Sinai follows, and a code of laws is given to the people, who form a theocracy, with rites sacrificial, after the fashion of their day, and a hereditary priesthood. The conquest of Canaan begins a new era—the period of the judges—but as the nation grows more warlike and becomes envious of its neighbors, the judge must give way to a king, and Saul, David, and Solomon successively reign. The builder of the temple, the central figure in Oriental legend, could not assure peace to his kingdom, and a division followed. Of the two kingdoms that of

Israel, with its capital first at Shechem and later at Samaria, was the more extensive and populous, embracing 10 of the tribes; but it was addicted to idolatry and fell captive to Sargon of Nineveh (721 B.C.). The kingdom of Judah, consisting of the tribes of Judah and Benjamin, was more faithful, but deplorably weak, and was conquered by Nebuchadnezzar, by whom the temple was destroyed (586 B.C.). In 536 B.C. Cyrus allowed the temple to be rebuilt, and in 516 B.C. it was finished under Ezra and Nehemiah.

Persian rule and influence, to which the Jew owed much, were succeeded by the sway of Egypt, not less vital for Judaism's growth. Under Ptolemy II. (Philadelphus), the Septuagint version of the Old Testament was written, which familiarized the Greek world with Jewish thought. Another change of masters subjected the Jew to Syrian supremacy, under which occurred the Maccabean revolt, followed by internal schism and a gradual weakening of national vitality under Herod, with Rome eager to despoil.

The Final Dispersion.—A fierce struggle to regain fatherland and liberty in the last days of Nero was fruitless. The temple was again destroyed, Jerusalem reduced to ruins, and the dispersion began in earnest (70 A.D.). A further revolt by Bar-Cochba, in the reign of Hadrian (132-135 B.C.) was ineffective. Jews were forbidden to enter Jerusalem, whose very name was changed to *Ælia Capitolina*.

A period of intense significance for Judaism had now arrived. It was to exchange one strip of land for the wide world, and for better or worse encounter new currents which were to change its form and destiny. The Palestinian phase was to give way to a broader development, which might have been a dangerous experiment if the Old Testament basis, the sacredness and authority of the law (*torah*) had not been retained. The remnant of Judah, however, met the issue with courage, and in every land of their dispersion managed to preserve a certain national character, due to their observance of national customs and traditions, while the ages of persecution only made them more firmly attached to their religion.

Jewish Learning.—The story of the Jews in the dispersion is a record of varied experience, a history written in sadness. The dispersion was a *via dolorosa* from land to land. Long before the final overthrow Jewish settlements were made in Italy and Asia Minor, in Egypt, North Africa and Babylonia. But now enforced exile scattered them in all directions. Happily the leaders concerned themselves with intellectual and spiritual factors, and in Palestine and Babylonia schools arose which were to preserve the religion and national consciousness more effectively than priest and sacrifice ever could have done. When Johanan ben Zakkai founded his school at Jamnia, while the ruins of Jerusalem were still smoking, the Romans were unaware that a power had arisen which was to maintain Judaism through centuries of Roman, Christian, and Mohammedan sway, and amid every mediæval and modern condition. The study of the law, the interpretation of tradition, the development of custom and prayer, the rise of synagogues, the organization of a distinct religious hierarchy, the birth of Talmudism; these were

JEWS AND JUDAISM

the factors which made the vanquished victors, and gave them life and influence when conquering races had passed away. It was fortunate that in the struggle between the Persian and Byzantine empires, as in later centuries between Caliph and Christian, or between rival pontiffs and emperors, the Jews were largely students, and had no "dark ages," such was the marvelous influence of their torah and Talmud, while in the conflict of opinions they preserved their intellectual vitality and breadth.

In the Middle Ages.—It is impossible within present limits to give more than a brief outline of the history of the Jews in the dispersion. With the breaking up of the Roman empire and the rise of Islam, the Jews began to feel the pressure of still other new masters, whose rule was not without its occasional gleams of sunshine. In the East, with Islam firmly settled in Persia and Mesopotamia, the condition of the Jews improved, their academies flourished, and a line of famous scholars, the gaonim, kept alive Jewish learning until 1036 A.D. In the West, chiefly in southern Europe and Spain, the spirit of persecution was rarely absent, although there were golden centuries in Spain under the caliphs, and learning flourished in France and Italy despite the enmity of pontiff and king. Jewish traders became the intermediaries in commerce; Jewish physicians were notable figures at the courts; and Jewish teachers gave instruction to lovers of learning. The liberal spirit of the caliphs at Bagdad, Cordova, and Cairo was emulated in Christian countries. In Spain, the Hebrew "Sepharad," the Jews enjoyed a high degree of favor under the caliphs (711-1150). They furnished ministers of state, scholars, scientists, poets of distinction. For 150 years (1150-1300) their condition under the Catholic kings was fairly prosperous. But soon restrictions became the order of the day, they lost the rights of Spanish citizens, were secluded in special quarters of their own, and massacres ensued, while some of their stateliest synagogues were converted into churches. This was the period when many Jews yielded to baptism, practising in private, however, Jewish rites: they were called "Marranos," or secret Jews, and included some of the noblest families in Spain. With the birth of the Inquisition at Seville in 1480, conditions became still more intolerable, and expulsion followed in 1492, 300,000 Jews leaving Spain. Four centuries later Spain was to offer shelter to Jewish refugees from Russian persecution; and its government is now restoring the famous synagogue at Toledo, which had been turned into a church, and showing a spirit of reparation that tells the story of humanity's progress.

The Jews in Modern History.—The exiles from Spain, the Sephardic branch of modern Jewry, found refuge in Italy and Holland, after a temporary stay in Portugal, where they took active part in the Renaissance. Great numbers, too, emigrated to Turkey. It was Elias Levita who, through his students, Sebastian Münster and Paul Fagius, introduced Hebrew studies into Germany, while Leo Hebraeus (Judah Abra-banel) was a famous Neoplatonist. Luis de Torres, a Jewish youth, participated in the quest of Columbus, and a Jew, the pilot Gaspar, aided Vasco da Gama in his search for a water-route to the Indies, whose plans, too, were assisted by Abraham Zacuto, the scholar and astronomer,

a teacher of the University of Salamanca, and later astronomer and chronographer to Manuel the Great of Portugal. Dark days followed the exile from Spain, and in the general sorrow mysticism spun its weird spell as the Cabala gained adherents, while the methodical study of the Talmud was to degenerate into one-sided scholasticism and intellectual jugglery. It was an era relieved, however, by some bright names. Joseph Nasi, Duke of Naxos, was a favorite of Sultan Selim II., who wished to make him king of Cyprus; Solomon Ashkenazi was Turkish ambassador to the republic of Venice; Benedict Spinoza, the thinker, and Sabbathai Zebi, the pseudo-Messiah, were products of the same century. Manasseh ben Israel, whose features were painted by Rembrandt, opened negotiations with Oliver Cromwell for the return of the Jews to England, from which land they had been banished in 1290. With the further migration of the Jews into Slavic countries and their closer segregation, due to the spirit of persecution, which was as bitter as in the era of the crusades, a new language or jargon—the Jewish-German—arose among them, which is now (1903) receiving careful scientific study. In the year of Luther's Pentateuch translation (1523) a Jewish-German dictionary appeared at Cracow, and in 1540 the first Jewish-German translation of the Pentateuch was issued there.

In the Middle Ages the charge of usury was often brought against the Jews, and doubtless was a motive for popular outbreaks against them. Usury is strictly prohibited by the Mosaic law. If, in ages when the Jew was disqualified from following agriculture or other ordinary pursuits, he had recourse to finance and often lent money at excessive rates, kings, nobles and priests were just as guilty, although the Jew was usually the scapegoat. "Every country has the Jews it deserves," is Karl Emil Franzos' pertinent saying. With civil and religious liberty there would be no cause for the ghetto, for narrow exclusiveness, for charges of usury, and other accusations. The 17th century, with the Thirty Years' War, which made nearly all of central Europe a battle-ground, had its full share of persecutions for the Jews, and many of the fairest communities were despoiled, the Jews in Poland losing 200,000 men, women, and children in the Cossack invasion (1648-51). That century marked the lowest ebb of Jewish life and aspiration. It was, fortunately, to be succeeded by the dawn of a new era. It was Moses Mendelssohn (1729-86) who strove to awaken his coreligionists to new life, and to rise to the level of the highest culture of their time, without abandoning the essentials of their religion. As his friend Lessing sought to emancipate German literature from French models, so Mendelssohn labored to free the Jew from mediævalism in thought and custom. It was a return to Jewish idealism and humanity that he advocated, a departure from the social and intellectual ghetto forced upon them by bigotry from within and without. From him dates the era of emancipation which was ushered in as well by the French Revolution. With their gradual acquirement of full citizenship in European lands, resolute changes in forms and ritual were imperative; and the mediæval atmosphere in prayer and ceremony was to pass away. Scholasticism was also to be overcome by Leopold Zunz (1794-1886) and the coterie of well-equipped scholars who opened

JEWS AND JUDAISM

a new path in the study of Jewish history and doctrine and showed the evolution of prayer and ceremony. With him were ranged S. L. Rapoport (1791-1867), S. D. Luzzatto (1800-65), Zacharias Frankel (1801-75), Abraham Geiger (1810-74), Samson R. Hirsch (1808-88), H. Graetz (1817-91), L. Loew (1811-75), Samuel Holdheim (1806-60), and the still surviving Moritz Steinschneider (1816).

To-day the condition of the Jews abroad may thus briefly be summarized: In Russia, Rumania, and Galicia, which contain the great majority of Israelites, they suffer social and political exactions, and are under strict mediæval restraint so far as their religious state is concerned. They are more or less rigid Talmudists, and are least influenced as a whole by the modern movement, although there are signs among them of new life. The revolution of 1848 completed the work of the French Revolution in assuring political equality to the Jews in Western Europe. In 1858 Lionel de Rothschild was the first Jew to take his seat in the English Parliament. London has had several Jewish lord mayors and a Jewish master of the rolls (Sir George Jessel). Anti-Semitism has rapidly lost its fangs in France, Austria, Hungary, and Germany, whose Jewish citizens are indistinguishable, save in religion, from those of other creeds. In Italy, Rome grants a site for a new synagogue not far from the Arch of Titus, mute witness of Israel's vitality. A Jew is Italian minister of war. What a transformation since the days when Jews were thrown to the lions or forced to live in the catacombs! As a result of the admission of Jews to every field of activity, they furnish their quota of famous names in all lands in music, art, science, literature, philanthropy, commerce, and politics.

Zionism, etc.—The Zionist movement of the past decade, so far as it aims at a restored Jewish nation in Palestine, numbers the largest body of adherents in Russia and Rumania; but with their full acquirement of political rights their attitude will change. Great Britain's offer of land in East Africa for a Jewish settlement under British sway is seriously considered by Dr. Herzl and the Zionists (1903), and may pave the way for practicable colonization both there and elsewhere, which will materially lighten the Jew's burden in persecuting lands, and give him new life and activity under more favorable conditions.

Continuity of Judaism.—The outline of Jewish history from the earliest times to the present, with observation of conditions throughout the world, proves that Judaism has always been a living religion in every environment and despite the cross-fertilization of ideas that it has encountered in Babylonia, Rome, Egypt, Persia, Arabia, Spain, mediæval Germany, and Italy. The law of adaptation has left its mark on the thought and principles of the Jewish belief. While the sources are in the Pentateuch or torah, the stream of Jewish tradition is continuous, and Judaism, practically the tradition of the Jews, may be defined as ethical monotheism illuminated by national customs and observances. A double stream of thought is to be discerned—a particularistic and a universal, exclusiveness and breadth, Jewry and the wide world, the God of Israel and the God of humanity. These tendencies appear not only in the Old Testament, but throughout the entire stretch of Jewish lit-

erature, and are still to be met in the views of modern rabbis of the various schools, old and new. But Judaism is none the less a fixed religion, even if it is difficult to define, and demands no assent to formal articles of belief. Its first intuition is belief in God, no blind power, but with the attributes of unity, incorporeality, eternity, omniscience, and omnipotence, and whose justice is tempered with mercy. The reality of revelation is its second principle, the revealings on Sinai through Moses, and their confirmation through the prophets of laws and statutes, the moral and ceremonial law—the immutability of the torah. As a necessary corollary comes a third principle, future reward or punishment for those who obey or transgress the law. Compensation in the hereafter implies the soul's immortality. Whatever varying views were held as to these principles and their interpretation by earlier and later rabbis, amid all exaggerations and aberrations to which they were subjected, giving rise to sect and schism, the ethical basis of Judaism was unquestioned, and action, not moralizing, was always the highest duty. The creed of Judaism has been defined from time to time by different rabbis, the most famous of whom, Maimonides (1130-1205), gave the most widely accepted exposition in 13 articles embodying these points: Belief in a creator, in His unity, incorporeality, eternity, and that He alone is to be worshipped; belief in prophecy, and that Moses was greatest of all prophets both before and after him; that the torah was revealed on Sinai, and possesses immutability; that God knows the thoughts and actions of men; belief in reward and punishment, in the coming of the Messiah, and in the resurrection of the dead. These articles were opposed by some of his contemporaries, as they have also been by some later rabbis, who frame different classes of doctrine or dogma and otherwise modify Maimonides' principles, which are still, however, regarded as authoritative by the large majority of Jews to-day. (See MAIMONIDES.)

Ceremonial and Festival Usages.—The ceremonial code and historic ritual are vital factors in the preservation of Judaism—"signs," and observances like circumcision, the Sabbath, the festivals, and the dietary laws. Their aim is to quarantine the Jew from idolatry and secure the permanence of his God-idea, and to ensure self-control over passion and appetite, promoting physical and moral growth, and maintaining family happiness and purity.

The chief Jewish festivals are the New Year, the Day of Atonement, Tabernacles, Passover, and Pentecost, with Purim, Hanukkah (to celebrate the victory of the Maccabees), and Fast of Ab, in memory of the fall of Jerusalem.

The breadth of Judaism is not to be lost sight of amid the many observances that are part of its historic programme. The Jew's original Semitism has developed into a cosmopolitanism which makes him a citizen of every land that assures him civil and religious liberty. He can be conservative in England, liberal in Germany, a formalist in France, a pietist in Poland, a mystic in Turkey, and can wear in the United States an intellectual coat of many colors that would astound his brethren in India. The breadth and catholicity of Judaism are organic; the Jew does not seek proselytes; he believes with Maimonides that "the pious of all nations

JEWS IN AMERICA

have a share in future bliss.⁹ His aspirations are not tribal; he believes in the perfectibility of humanity; and whether his Messiah be a person or an epoch, he holds that the time will come when all men will acknowledge the unity of God and the brotherhood of man.

Jewish Statistics.—The figures of Jewish population, as contained in the 'American Jewish Year Book' for 1900-01, are herewith given. For the British Empire the total is 148,149, divided as follows: England, 97,350; India, 17,194; Australia, 15,268; Canada, 6,414. For other countries: Austria-Hungary, 1,871,414; Russia, 5,700,000; Rumania, 300,000; Germany, 567,884; Turkey, 350,000; France, 72,000; Italy, 50,000; Netherlands, 97,324; Egypt, 25,200; Morocco, 150,000; Belgium, 4,000; Argentina, 6,735; Denmark, 4,080; Greece, 5,792; Persia, 50,000; Serbia, 4,652; South Africa, 10,000; Switzerland, 8,069; Sweden and Norway, 3,402; Spain, 2,500; Peru, 498; Bulgaria, 22,617; Venezuela, 411; Abyssinia, 120,000; China, 300; Algeria, 43,500; Tunis, 4,500; Curaçao, 831; Surinam, 1,250; making, with the United States (1,200,000), a total of about 11,000,000 for the world. For Jewish statistics of the United States see JEWS IN AMERICA.

Bibliography.—Among the more important ethical and philosophical writings of the rabbis which are generally regarded as setting forth what is characteristic in Judaism—not to refer to special works of one-sided tendency—the following are recommended: Saadya (10th century), 'Emunoth Vedeoth' (Beliefs and Opinions); Bachya (11th century), 'Choboth Ha Lebaboth' (Duties of the Heart); Hallevi (12th century), 'Cuzari'; Maimonides (12th century), 'More Nebuchim' (Guide of the Perplexed); Albo (15th century), 'Sefer Ikkarim'; Troki (16th century), 'Chizzuk Emunah'; Mendelssohn (18th century), 'Jerusalem.' For general information on the subject of Jews and Judaism may be read: Graetz's 'History of the Jews'; Morris Joseph's 'Judaism as Creed and Life'; Stanley's 'History of the Jewish Church'; Daly's 'The Settlement of the Jews in North America'; Kayserling's 'Christopher Columbus and the Participation of the Jews in the Spanish and Portuguese Discoveries'; 'Publications of the American Jewish Historical Society'; Schechter's 'Studies in Judaism,' and many issues of the American Jewish Publication Society. Within recent years in particular a rich and extensive literature has sprung up in this line of study in England, Germany, France, Russia, Italy, and elsewhere.

A. S. Isaacs,
Prof. German Literature, New York University.

Jews in America. Although the Jewish population of America has been greatly increased by immigration only since 1881, Jews have been closely identified with American history for centuries, and some of that race even settled in this country in Columbus' day.

Before taking up the history of the Jews in America, some statistics concerning the American-Jewish population at various periods will be in order, as tending to throw light on more isolated historical incidents relating, for the most part, to the experience of a small fraction only.

Statistics.—The latest and most authoritative statistics as to the present Jewish population

of the United States are furnished by the 'American Jewish Year Book' (September 1903), wherein it is computed that the total number of Jews in this country is 1,127,268, of whom 500,000 are credited to New York State, 28,000 to California, 75,000 to Illinois, 25,000 to Indiana, 26,500 to Maryland, 60,000 to Massachusetts, 50,000 to Missouri, 25,000 to New Jersey, 50,000 to Ohio, and 95,000 to Pennsylvania; all the other States and Territories, including Hawaii, Porto Rico, and the Philippine Islands, and also the District of Columbia, likewise containing some Jewish residents. In making up this total, account is taken of the fact that 761,598 Jewish immigrants arrived at the ports of New York, Philadelphia, and Baltimore from 1881 to 1 July 1903. The same authority computes the Jewish population of America, exclusive of the United States, as follows: Canada and British Columbia, 25,000; British West Indies, approximately, 2,500; Argentina, 22,500; Brazil, 3,000; Cuba, 4,000; Mexico, 1,000; Curaçao, 103; Surinam (Dutch Guiana), 1,121, and Venezuela 411; making 1,186,903 in all for America. These figures are mere estimates, than which nothing more accurate is at present obtainable; but they are no doubt approximately correct, being based upon partial actual counts, analyses of death-rates, and reports of competent judges in the various localities; and having also been reviewed from time to time in the light of criticism and new data. If anything, the figures are probably somewhat too low, the city of New York, in its five boroughs, being credited by competent judges in 1903 with a population of over 600,000 Jews, which would make the estimate for the State above quoted about 150,000 too low. Estimates for other districts are also likely to be low; although that given for Cuba is undoubtedly too high. In rough figures, then, the Jewish population of the United States to-day may be estimated at 1,200,000.

The first systematic attempt to secure statistics of the Jewish population in the United States culminated in the publication of a report by the Union of American Hebrew Congregations in 1880, giving estimates for each State and city in the Union, and aggregating 230,257 persons. In connection with the national census of 1890 statistical information was gathered regarding Jewish congregations in the United States, and the total number of Jewish communicants was estimated at 130,496, belonging to 533 church organizations. Of these, 316 organizations, having 122 church edifices, valued at \$2,802,050, and 51,597 communicants, are to be credited to Orthodox Judaism, while Reform Judaism counted 217 organizations, having 179 church edifices, valued at \$6,952,225, and 72,899 communicants. A very large majority of the Jewish immigrants arriving in the United States since 1890 belong to the orthodox wing, and even the figures of 1890 undoubtedly disregard numerous small, often unorganized, orthodox congregations, from whom it was relatively more difficult to secure reports. In 1818 the Jewish population of the United States was estimated at 3,000 only; in 1848, at 50,000. In South America there were several thousand Jews prior to 1650, the greater part of whom were in Brazil, as noted below; but hostile laws and the persecutions of the Inquisition, while driving some

JEWS IN AMERICA

to the West Indies, and even as far north as New Netherlands, caused several thousand Jewish settlers in Spanish and Portuguese territories to totally give up their Jewish identity.

It might be said that there were successive tides of Jewish emigration to America from European countries, fairly well separated from each other in point of time. During the first 250 years after the discovery of America the settlers were mainly Jewish immigrants of Spanish-Portuguese stock, with only an occasional sprinkling of German, French, English, and Polish Jews. German Jewish emigration becomes considerable only a short time before the American Revolution (though evidence is accumulating that it took upon itself larger dimensions and at an earlier period than is commonly believed); it was stimulated by the reactionary measures following the Napoleonic wars and the revolution of 1848, and began to include emigrants from the Austro-Hungarian empire, and later on an increasing number of Poles. The Russian-Jewish exodus, which began about 1881, was by far the heaviest of these various currents of emigration, and was itself succeeded or joined by a Rumanian-Jewish wave about 1900. For Jewish statistics of other countries see JEWS AND JUDAISM.

Jews in the Spanish and Portuguese Colonies.—Before the discovery Jews were actively identified with the fate of America, as may be said without reference to the curious and once widely accepted theory that the American Indians are descendants of the lost Ten Tribes. Emilio Castelar, the late Spanish statesman and historian, referring to the coincidence that the Jews were expelled from Spain in the year that Columbus started on his first voyage of discovery—a circumstance noted by Columbus himself in his journal, and repeatedly thereafter commented upon by Jewish historians—makes this observation:

It chanced that one of the last vessels transporting into exile the Jews expelled from Spain by the religious intolerance of which the recently created and odious Tribunal of the Faith was the embodiment, passed by the little fleet bound in search of another world, whose creation should be new-born, a haven be afforded to the quickening principle of human liberty, and a temple reared to the God of enfranchised and redeemed consciences.

But Jewish aid to Columbus was not limited to Jews accompanying him on this first voyage (including Luis de Torres, a new convert to Christianity, who went as interpreter because of his knowledge of Arabic, and settled before 1500 in America), nor to the circumstance that Columbus carried with him, as aids on his voyage, a sea-quadrant called "Jacob's Staff," invented by a Spanish Jew, and astronomical tables and charts invented by another Jew. The more significant and important fact is that Jewish financiers at the Spanish court were his leading patrons, and advanced the money for his voyage, as evidenced by original account-books still found in the Spanish archives; so that it was a mere recognition of this circumstance that induced him to address the first two letters (now justly famous, and the earliest copies of printed editions of which command thousands of dollars from book-fanciers) narrating his discovery to those two secret Jewish friends, Louis de Santangel, chancellor of Aragon, and Gabriel Sanchez, royal treasurer. In the light

of such facts the late Herbert B. Adams wrote that "not jewels, but Jews, were the real financial basis of the first expedition of Columbus." The revenues needed to fit out the second expedition were secured from the proceeds of the property, of which the expelled Spanish Jews were despoiled by the Inquisition at the time of their expulsion from Spain.

In spite of prohibitions upon Jewish settlement in Spanish and Portuguese America, many Jews rapidly emigrated to the New World from among those exiled from Spain and Portugal; occasionally, in spite of the inconsistency involved, in view of those prohibitions, Jews and Jewesses were forcibly transported to America by the state through the agency of the Inquisition. By 1548 Jews are referred to not merely as having settled in Brazil, but as introducing sugar-culture there, which they transplanted from Madeira. The smoking of tobacco had been introduced to Europeans even before 1500 by Luis de Torres, a companion of Columbus. Occasionally, enormous sums of money had to be raised and given to the crown in order to effect suspensions or revocations of prohibitions upon Jewish settlement in the Spanish and Portuguese colonies. But the Inquisition and its terrors were introduced even into the New World; hence Jews found it advisable to try to conceal their faith under the cloak of Christianity; and it is principally in the records of the Inquisition that we find proofs of the Jewish practices of many of these settlers—called Marranos or secret Jews—whose trials commonly resulted in imprisonment, frequently in death at the stake, and were at all events followed by confiscation of their property.

In Brazil, Jewish settlers actively aided the Dutch in effecting their conquest of that country, about 1620, after which the Jews *en masse* threw off their Christian disguise and publicly professed their own religion. The Dutch West India Company (q.v.), which obtained the proprietorship of Brazil, had many influential Jewish stockholders, and under their auspices large numbers of Jews from Portugal, Holland, and Germany immigrated. Jewish residents are referred to about 1640 as owning the principal sugar-plantations of Brazil, and as heavily interested in the diamond industry then developing there; and there is also evidence that a Jewish literature sprang up in Brazil at this time. Some idea of their numbers may be gathered from the fact that at the time of the surrender of Recife (Pernambuco) to the Portuguese, after its recapture from the Dutch, soon after the middle of the 17th century, that city alone contained about 5,000 Jews, even after many had departed from the city. In smaller numbers they were also established in other cities of Brazil, in Mexico, Peru, the West Indies, and at other points. The Dutch capitulation of Brazil in 1654 led to their flight in large numbers from that country, their migrations leading them northward, particularly to the West Indies, and one party of refugees even becoming the nucleus of a Jewish settlement at New Amsterdam (New York city) in 1654. Many, however, remained in the South American colonies, and their Jewish identity was gradually lost under the hostile influences at work. The settlements under Dutch auspices at Surinam,

JEWS IN AMERICA

Cayenne, and Curaçao, are deserving of particular attention.

Of the professing Jewish inhabitants now to be found in these districts, enumerated in the statistics just considered, very few are descendants of the original Spanish settlers, the great bulk of them being comparatively recent arrivals from Germany, Russia, and Rumania. Through the munificence of Baron de Hirsch (q.v.) millions of dollars were employed about 1891 in the purchase of land and equipment for the use of agricultural colonies of Russian Jews established under his auspices in Argentina, where several thousand Jews settled, though they have met with only moderate success.

West Indies.—Reference has already been made to early settlements of Jews in Cuba and other West Indian islands. Their settlement in Jamaica was particularly important on account of their numbers and the once great commercial importance of the island. For the latter reason, their residence in the Barbados, at St. Eustatius, Martinique, and in the Danish West Indian colonies also led to important consequences. Reference will be made hereafter to this circumstance. Except in Cuba, the decline of the above named places commercially has caused a decided diminution in the number of their Jewish inhabitants, and to-day the chief interest in the settlements is historical.

Early Settlements in the United States before the Revolution.—There are indications of some isolated and casual arrivals of individual Jews within the present limits of the United States prior to the arrival of the party from Brazil in colonial New York during the Dutch régime, in 1654; these were in Maryland, Virginia, and New England, to say nothing of a party of Jewish soldiers and sailors who seem to have reached New Netherlands (New York) in 1652. These instances (other than those in the Dutch colony) are purely casual, however, and unimportant, because Jews were not allowed at this time to live as avowed Jews in any of the principal countries that then had colonies in America except Holland. Prohibitions against their settlement were in force (though occasionally ignored) in Spain, Portugal, England, and to some extent in France. Holland alone at this time welcomed the Jewish refugee, to her great commercial advantage; and this "common harbor of all opinions and of all heresies" was, logically enough, destined to establish a precedent for granting religious liberty also in the New World. It is true that in New Netherlands Governor Peter Stuyvesant (q.v.) was decidedly hostile to the Jewish arrivals, as were also some of the early Dutch ecclesiastical authorities; but, thanks to the leveling and humanizing influence of commerce, and to Jewish holdings of stock in the Dutch West India Company, the directors of that company, 26 April 1655, instructed their governor that the "Jews shall have permission to sail to and trade in New Netherlands, and to live and remain there, provided the poor among them shall not become a burden to the company, or to the community, but be supported by their own nation"; and Stuyvesant was strongly reproved soon after for seeking to thwart these clearly expressed wishes of the company. The emancipation of Jews was, however, only gradual; certain restrictions were continued through

the whole colonial period, though they decreased from time to time, and in importance. Public worship, as distinguished from private religious services, was forbidden them till near the close of the 17th century, as was also selling at retail, and certain political rights of citizenship were also denied; but these restrictions in the course of time were largely removed in practice, so that the adoption of the first constitution of the State of New York, in the Revolutionary period, which established absolute religious liberty, conferred in effect few, if any, privileges on the Jewish residents of that State, which they had not already virtually enjoyed. In the interior, the number of Jewish residents had grown somewhat by emigration from Germany, Hungary, Poland, and also from England, which, under Cromwell, readmitted the Jews soon after the time of their settlement in New Netherlands; but the increase in numbers through immigration was not great till after 1800, for there were few Jews in England, and still fewer who desired to emigrate from there, while emigration to New York and New England prior to the above date from any of the other designated countries was very small.

To Newport, R. I., Jews emigrated very soon after they first settled in New Amsterdam, and Roger Williams (q.v.) in terms included them in his programme for establishing a colony where religious liberty would be accorded to all sects and creeds. In the course of time they erected a synagogue here also, as well as in New York, and established a community which contributed most materially to the commercial prosperity of Newport, which city far outrivaled New York for some decades before the Revolution, and until, during that struggle, its shipping interests received a blow from which they never wholly recovered. Here also, there were some retrogressions during the colonial period from Roger Williams' enlightened declaration of principles; but on the whole, Jews were most prosperous residents of Newport during the latter portion of the colonial period. Even though the colony never was numerous, it embraced such merchant princes as Aaron Lopez and Jacob Rodrigues Rivera, and its fortunes were commemorated, after all the old-time residents had departed, in Longfellow's famous lines on "The Jewish Cemetery at Newport." Already in the colonial period Jewish settlers occasionally found their way into Connecticut, also to Boston, and even, it would seem, to Maine, but they were very few in number, and the present Jewish residents of New England date almost entirely from the period of German settlement after 1848, followed by a much more considerable Polish and Russian-Jewish settlement toward the end of the 19th century. About 1820 Major Mordecai M. Noah, at one time United States Consul to Tunis, developed a fantastic plan for founding a Jewish state for the oppressed Jews of other lands under his own "judgeship," near Niagara Falls, at a place he named, "Ararat, City of Refuge," and attempted to tax all the Jews throughout the world for this purpose, but the scheme merely aroused amused attention. Other less ambitious early colonization schemes also were formed.

Pennsylvania, under William Penn's generous plan for founding a home for victims of persecution, attracted Jewish settlers, and in the early

JEWS IN AMERICA

decades of the 18th century a little stream of immigration began which brought a number of German, English, and Polish Jewish settlers to the colony, whose numbers were increased, after the capture of New York by the British in 1776, by the arrival of Portuguese Jews from that city. The Jewish settlement in Lancaster, Pa., was made about the time of the American Revolution; and there was a small Jewish immigration into Maryland and Virginia, with communities in Schaefersville, Easton, Baltimore, and Richmond. Before the close of the Revolution a Portuguese synagogue had been erected in Philadelphia; soon a German Jewish congregation was established there; and about the same period one was erected in Richmond, Va. The laws of Maryland prohibited Jewish settlement, and as early as 1658, Dr. Jacob Lumbrozo, "the Jew physician," figured there as defendant in a blasphemy trial, which nearly cost him his life. Baltimore is of particular interest because it was the only city in the United States in which systematic and long-continued efforts were necessary, subsequent to the Revolution, in order to secure full civil and political rights for Jews as such: they acquired them finally in 1826. Georgia attracted Jews almost immediately after the founding of the colony, parties of both German and Portuguese Jewish settlers having arrived at Savannah in 1733. Some of these were indigent Jews, who were assisted to emigrate by coreligionists in England. Offshoots from this colony migrated to South Carolina before the first half of the 18th century, and a congregation was formed in Charleston in 1750. By the time of the Revolution, and for some decades thereafter, Charleston contained one of the most important and prosperous Jewish communities in the United States. In both of these colonies Jews seem to have figured as holders of responsible civil office before the close of the Revolutionary War.

The various places which contained Jewish communities prior to the Revolution have now been enumerated; the total Jewish population embraced in them and in other and more isolated settlements was, as seen, somewhat less than 3,000 in the year 1800.
